	PAGE		PAGE
A		Charlton, Dickinson & Co., Professional Customs	615
Abandoned Project, Editorial	2	Chase, A. B., The Caving System at the Darlen Mine	238
Abbe, Paul O., Spiral Feed for Tube-Mills	144	Charging of Blast-Furnaces, E. H. Messiter	528
Abbott, James W., A Fundamental Problem	143	Chloride Solutions, Copper in, Gustave Fernekes	592
Abt, Ploche, Nevada	176	Choix-Guadalupe y Calvo Mining Districts	636
Abt, Professional Customs	617	Circumstances, Mining Under Adverse	E. McCormick
Abt, Professional Customs	617	Clark, Albert L., Wall Street	808
Abt, Professional Customs	617	Clean-Up, Melting, and Refining of Gold Bullion	277
Abt, Professional Customs	617	Coal Fields, Alaska	89
Abt, Professional Customs	617	Mines, Fatalities in, Editorial	792
Abt, Professional Customs	617	Mineral in California	186
Abt, Professional Customs	617	Cobalt, Frank C. Loring	814
Abt, Professional Customs	617	Coffee Creek Mining District, The Geology of the	25
Abt, Professional Customs	617	Collins, Edgar A., The Combination Mine	397
Abt, Professional Customs	617	Collins, George E., A Fundamental Problem	79
Abt, Professional Customs	617	Colorado, Lodes in the Tertiary Eruptives of	180
Abt, Professional Customs	617	Combination Mine, Edgar A. Collins	397
Abt, Professional Customs	617	Compressed Air, Hose Connections	314
Abt, Professional Customs	617	In Cyanidation, Andrew F. Crosse	560
Abt, Professional Customs	617	Comstock Lode, The Great, G. McMillan	168
Abt, Professional Customs	617	Concentration of Slime, Wilton E. Darrow	268
Abt, Professional Customs	617	Concluding Notes on Guanajuato, T. A. Rickard	83
Abt, Professional Customs	617	Concrete, Reinforced, Editorial	507
Abt, Professional Customs	617	Tank to Store Tailing	237
Abt, Professional Customs	617	Conditions at Goldfield, Editorial	724
Abt, Professional Customs	617	Congress, The Mining, Editorial	631
Abt, Professional Customs	617	Construction of a Gasoline Assay-Furnace	719
Abt, Professional Customs	617	Of Wooden Trestles, R. Balfour	152
Abt, Professional Customs	617	Converter Hood, L. S. Austin	100
Abt, Professional Customs	617	Converters, Hydraulically Operated, Copper	375
Abt, Professional Customs	617	Conveying Tailing in Launderers, G. A. Overstrom	332
Abt, Professional Customs	617	Ditto, C. W. Van Law	157
Abt, Professional Customs	617	Tailing Through Pipe, C. W. Van Law	78
Abt, Professional Customs	617	Copper, Editorial	374
Abt, Professional Customs	617	Converters, Hydraulically Operated	375
Abt, Professional Customs	617	In Chloride Solutions, Gustave Fernekes	592
Abt, Professional Customs	617	Market, Editorial	285
Abt, Professional Customs	617	Statistical, James Douglas	520
Abt, Professional Customs	617	The Price of, Editorial	380
Abt, Professional Customs	617	Production of, Editorial	151
Abt, Professional Customs	617	Secondary Ores of, H. E. West	111
Abt, Professional Customs	617	The Uses of, Lewis T. Wright	161
Abt, Professional Customs	617	Core-Drill in Prospecting, The Diamond	222
Abt, Professional Customs	617	Corporation, Zinc, Editorial	662
Abt, Professional Customs	617	Correctives, Financial, Editorial	645
Abt, Professional Customs	617	Cost of Filtering, E. Burt	96
Abt, Professional Customs	617	Of Mining, Ross E. Browne	113
Abt, Professional Customs	617	Crisis, Financial, Henry A. Wise Wood	791
Abt, Professional Customs	617	In San Francisco, Editorial	412
Abt, Professional Customs	617	Lessons of the, Editorial	566
Abt, Professional Customs	617	Crosse, Andrew F., Compressed Air in Cyanidation	560
Abt, Professional Customs	617	Crystals and Water in Veins, Editorial	190
Abt, Professional Customs	617	Cuchillo Parado District, R. H. Burrows	108
Abt, Professional Customs	617	Cullinan Diamond, Editorial	221
Abt, Professional Customs	617	Curiosities of Mining, Mark R. Lamb	521
Abt, Professional Customs	617	Curle, J. H., Present Status of the Gold Mining	147
Abt, Professional Customs	617	Industry, Andrew F. Crosse	560
Abt, Professional Customs	617	Cyanidation, Compressed Air in, Philp Argall	655
Abt, Professional Customs	617	History of (I. H.), R. Stuart Browne	677
Abt, Professional Customs	617	In Nevada, G. A. Denny	111
Abt, Professional Customs	617	In the Transvaal, G. A. Denny	111
Abt, Professional Customs	617	Of Ore Containing Both Coarse and Fine Gold	709
Abt, Professional Customs	617	Ditto, E. M. Hamilton	715
Abt, Professional Customs	617	Ditto, Edward H. Sutter	742
Abt, Professional Customs	617	Ditto, C. W. Van Law	742
Abt, Professional Customs	617	Slime Ore for, Mark R. Lamb	658
Abt, Professional Customs	617	With the Brown Vat, Francisco Narvaez	689
Abt, Professional Customs	617	Cyanide Filter, The Burt Rapid	717
Abt, Professional Customs	617	Practice at Copala, Dana G. Putnam	645
Abt, Professional Customs	617	Practice at the Homestake Mills, F. L. Bosquell	21
B		D	
Bad Ground, Sinking Through, F. W. Adgate	183	Daniels, Joseph, Deep Thinking	521
Baker, Arthur, Esperanto	811	Darlen Mine, Caving System at the, A. B. Chase	238

Editorial.

WE SHARE the pleasure of this community in learning that Mr. Benjamin Ide Wheeler will remain President of the University of California despite the opportunity to become the executive head of the Massachusetts Institute of Technology. That a professor of Greek should have received the offer of the presidency of a technological college immediately after it had been declined by a professor of Latin goes to prove that men of scientific or technical training are not available for the purpose. It suggests either that professors of science lack executive ability or that successful technical men cannot afford to accept positions of this kind.

HOMESTAKE MILLING PRACTICE has become an altogether different procedure from what it used to be. Ten years ago the methods in use were mainly interesting for their incompleteness, but since Mr. C. W. Merrill became advisory metallurgist, the treatment, after stamping, has become not only modern but original. In filtering of slime and in other details of cyanidation (such as precipitation of the gold) Mr. Merrill has led the way by suggestive improvements. For these reasons we are glad to publish the excellent article by our friend Mr. F. L. Bosqui, himself an authority, as he is a specialist, on the cyanide process.

SUGGESTIONS FOR FIELD OBSERVATIONS are likely to be useful to mining engineers, and particularly when they are offered by such a geologist as Mr. S. F. Emmons. Hints of this kind are invaluable to the younger men in the profession, for they do most of the scouting for the veterans, whose duty it is mainly to make inferences from facts collected by their more active assistants. The three pages that Mr. Emmons has contributed will find their way into the notebooks of many of our readers, for they epitomize the main structural and chemical features of ore deposits. A few copies will be prepared in pamphlet form, for gratuitous distribution to those that ask for them.

OUR CORRESPONDENT at Johannesburg and Mr. Edgar P. Rathbone, late Inspector of Mines to the Transvaal Government, both contribute a few remarks upon the labor situation on the Rand. The cost of ordinary labor is the vital factor in large mining operations and at times we are apt to forget it when emphasizing the value of mechanical devices and new processes. The history of ancient mining demonstrates this vital fact, for forced labor ensured economy even without the mechanical appliances now deemed essential. Tube-mills and slime-filters at Johannesburg are secondary to Kafir and coolie labor; the former may save one or two per cent in costs, the latter represent a saving of 10 or 20 per cent as compared to other labor available.

In most mining districts of the United States the labor cost represents from 65 to 80 per cent of the total expenditure at a mine. In Mexico it is 55 to 58 per cent.

OUR contemporary, *The Canadian Mining Journal*, contains an article on the Boston Richardson Mining Company's work in Nova Scotia. It does credit to the author, Mr. Percy Brown, and emphasizes the narrow margin under which gold is won from the 'saddle reefs' of the eastern Province of Canada. Furthermore, it testifies to careful management when ore yielding \$2.70 can be exploited to advantage.

ABSOLUTE STAGNATION marks the mining business of London at the present time. Ever since the war South African shares have been declining until now the hopes of a revival have vanished. The recent labor disturbances have had a bad effect, although this is a small and temporary factor as compared to the interference of the Liberal Government with the regulation of Chinese labor. All the speculators except the biggest financiers have seen their profits vanish, and many men that came home from the Rand with a handsome competence are now facing poverty. In the Siberian department there has been a collapse, and in the Australian stocks the failure of the plans of the Zinc Corporation and the Deep Leads has had a bad effect. On the whole, the mining market is under the gloom of a funereal fog. It is a time of reaction from excessive speculation. Happier days will come after a period of readjustment.

AN ENGLISH RAND is the alluring title of a supposititious goldfield in Gloucestershire. Our London correspondent has referred to some of the incidents connected with this interesting episode in British mine speculation. It has all the characteristics of former funny happenings. In the first place the Chastan Syndicate, which is the company of issue, has for its chairman Admiral Sir Henry F. Nicholson, K. C. B., undoubtedly a worthy sailor and a skillful commander, but sadly out of place as the head of a scheme to dig gold out of the ground. Now, if R. T. Bayliss, Walter McDermott, Edgar Taylor, J. H. Curle, or some other knowing gentleman, someone saturated with experience in the various forms of gold mining, had been selected as chairman, we would have considered it a strong point—but these Admirals, Generals, and noble Earls that lend themselves to industrial enterprises have no sense of humor. They are plainly absurd. It ought to be recognized that such practices become serious when good names are used as lures for subscriptions to stock and as a guaranty of respectable business. They succeed in their first purpose and fail wholly as to the second. However, that is another story. The English Rand, as this gold-bearing territory in Gloucestershire is labeled, has been examined by several engineers. The property covers leases aggregating 1,814 acres and "commands the reef" for 12 miles. There is a persistent layer of conglomerate; it is said to be like the blanket of the Rand and West Africa; it is said to be uniformly gold-bearing; it is

claimed to be rich enough to be profitably exploited. The first of these statements meets with undoubted confirmation; the second is affirmed without objection; the third is doubted; the fourth is vigorously denied. After the shares had fluctuated wildly on the Stock Exchange a firm of reputable engineers was engaged by leading shareholders, and the report was unfavorable. Messrs. McCarthy and Halse took samples and found the conglomerate to contain 6 grains of gold (that is, about 24 cents) per ton, in other words, they confirmed the geological occurrence of a large body of gold-bearing conglomerate and disproved the supposition that it could be made the basis of a profitable mining enterprise. Thereupon, the directors tried to excuse the finding of these engineers by stating that the samples were "taken absolutely from the surface and very small in size and weight," thus introducing two time-worn fallacies, namely, that depth is necessary in gold mining and that large bulk samples are required in ascertaining the average content of a lode. This episode illustrates the conditions most likely to bring mining companies to grief. Apparently the chairman is an admiral and the directors are at sea.

An Abandoned Project.

WE HAVE REASON to believe that the plans of the Guggenheims to build a big smelter close to San Francisco have miscarried. Work is being stopped at San Bruno. A large part of the machinery intended for this plant has been diverted to Ely and to other smelters controlled by the American Smelting & Refining Company. In their decision to drop the project it is probable that two factors were responsible; the first being the failure of the Dairy Farm mine in Placer county, California, from which a large supply of copper ore was expected. At 500 feet the orebody became lean and it is now quite evident that this mine cannot do what was expected of it. The other reason for stopping work at San Bruno was the strong protest and organized opposition of the citizens of San Mateo, who claimed that the sulphurous and arsenical fumes would kill vegetation and cattle. This was based largely on error and prejudice, assisted by a professor of chemistry who was an expert witness against the Anaconda Company; it seemed to us that the position of the smelter people was strong, for they were entitled to complete their plant and to prove that, with the sulphuric acid annex, they could mitigate any possible nuisance caused by obnoxious fumes. However, that problem will not be tested, it appears now, and the people of San Mateo will be able to buy the smelter site and erect upon it a chemical brewery, an oil refinery, a tannery, or some other sweetly smelling manufactory. Most of the grading, retaining walls, and foundations, besides railroad tracks, have been completed, so that the smelter company has done a good deal of work that will be useful to others. The episode is regrettable. A large smelter near San Francisco would have stimulated local industry and emphasized the importance of the City as a technical centre. In the opposition to the project, the Guggen-

heims suffered from their own exaggerated talk of the tonnage to be treated, 5,000 tons per day being mentioned at one time, although the plant was to begin with a capacity of 1,000 tons daily. This had the effect of warning possible competitors, such as Schwab and others, to keep off the field, but it excited the owners of villas and orchards at San Mateo and Burlingame. In the meanwhile the fiasco of the Dairy Farm mine was probably the most decisive factor and it goes to prove that smelters dependent on single mines are in a precarious condition unless ample precautions are taken to prove the ore reserves. The decisions in the smelter-smoke cases at Salt Lake were given after the San Bruno project had been started, as also the judgment obtained by the State of Georgia against the Tennessee smelters. These afford unpleasant precedents. In this matter the smelting companies have suffered from blackmailing and ignorance, as much as from their own doings, but back of it all is their carelessness and lack of consideration for the rest of the community. To put smelters in the middle of a distinctively agricultural region like that of the Salt Lake Valley was to invite trouble. There is plenty of desert land in the same State where fumes could injure only sagebrush and rabbits. For the San Bruno enterprise there was much better excuse; the projectors of it wanted to be at tide-water and near a large distributing centre. They chose a site least likely to interfere with others and they purposed to employ every known device to mitigate injury from the smoke. They have suffered from the reckless action of the smelter managers elsewhere. It is time for metallurgists to tackle this subject earnestly. All of us that are interested in the welfare of the mining industry appreciate the importance of the smelting department; if the smelters are driven out of business, the mines and miners will suffer. In the first place, we refuse to believe that the skill of the chemist and metallurgist is beaten, we expect to see the invention and application of devices perfectly able to prevent the destructive escape of noxious fumes. The manufacture of sulphuric acid is one of them; it can be used for making superphosphate, which is a valuable fertilizer, more marketable however on the Atlantic coast than here. Next, sites must be chosen where the ineffective smothering of smoke will not render the smelter liable to blackmail and persecution. It is argued that if a smelter makes a desert within a radius of 15 miles, the owners of such an establishment ought to buy a tract of desert land of equal dimensions and erect their plant there, where none will molest them and they will molest none. This is the last resort. Smelters need water and fuel, besides labor and supplies. These are more expensive in deserts than in fruitful valleys. That there is injustice on the part of the community and carelessness on the side of the smelter people, is proved by such exceptions as the Tacoma smelter, next door to a beautiful park, by the three Denver smelters, on the immediate outskirts of a large and handsome city, and by the five smelters at work in the thickly populated environs of New York. In all of these cases a little care on one side and a little

fairness on the other have obviated interference with one of the most useful forms of human enterprise.

Mint Purchases of Silver.

THE Director of the Mint has issued an order making a change in the regulations governing the receipt and payment for bullion, and it is interesting because these regulations have existed ever since the Government undertook to refine its purchases of gold and silver. The order reads: "From and after July 1, 1907, the deduction of $\frac{1}{100}$ of the standard weight of gold from silver contained in deposits at the mints and assay offices of the United States, will be discontinued. The depositor will be paid for the full weight of the silver contained in the deposit, based on the Assayer's report." This is an important matter to depositors of bullion. In the past it has been the custom to deduct from the silver contents an amount equal to $\frac{1}{100}$ of the standard weight of the gold in such deposits, that is, the depositor did not receive pay for that amount of silver. The justification for this deduction lay in the fact that it was impracticable to make a complete separation of the silver and gold in the refining operation, and that the amount of silver retained by the gold was equal to $\frac{1}{100}$ of the weight of the gold. Under the old process, of refining with nitric acid, this was true. Of course, a more complete separation of the metals could be obtained, but at such expense as to make it too costly and therefore impracticable, and this silver remaining with the gold was figured as part of the alloy in preparing the bullion for coinage operations. To illustrate; if it was found there were 10 parts of silver (out of a thousand) still remaining with the gold, then it was only necessary for the melter and refiner to add 90 parts of copper, whereas if the gold was pure he would be required to add 100 parts of copper. But about twenty-five years ago sulphuric acid replaced nitric in the process of refining; this was more economical, and therefore it became practicable to obtain a more thorough separation of the silver from the gold, according to the quality of the acid. The fineness of the gold obtained through this process varied from 990 to 997.5 per thousand, but no change was made in the manner of settling with the depositors. In the last few years the Government has been perfecting an electrolytic process of refining, which results in obtaining almost pure metal in either gold or silver at a still less cost than in the other process heretofore used, and therefore the Director of the Mint has apparently found that there was no further reason or justification in withholding from the depositor any part of his silver, it being all recovered, with a complete separation of the two metals. The experimental work of perfecting the electrolytic process has been done at the Philadelphia Mint, and after reaching satisfactory results, an electrolytic refinery was recently installed in the Denver Mint upon the completion of the new building there, and the new system is also being placed in the New York Assay Office. At the present time the work of installing the new process is going on in San Francisco, the last charge under the sulphuric acid process having been returned from the old refinery at this Mint last week.

Personal.

H. C. HOOVER is at Melbourne.

CHARLES MOLSON is at New York.

WILLIAM M. MEIN has returned to Johannesburg.

H. K. WHEELER, of Los Angeles, is examining mines in Arizona.

ALBERT BURCH is on his way to southern Chihuahua, Mexico.

JOSEPH C. HOPPER will remain in England until September.

T. E. SCHWARTZ has returned to Denver from southern Arizona.

PHILIP L. FOSTER is on his way from New York to London.

J. H. CURLE was here this week. He is now on his way to London.

JOSEPH L. GIROUX has returned to Los Angeles from New York.

JAMES W. NEILL has been to look at the copper mines of Yerington, Nevada.

T. B. BASSETT left Los Angeles on June 29 to examine mines in Sonora, Mexico.

CHARLES E. KNOX is general manager for the Montana-Tonopah Mining Company.

FRANK OLDFIELD was married at Pittsburg on June 22. He is now at Reno, Nevada.

R. J. FRECHEVILLE is examining the copper mines of Tanganyika, in central Africa.

W. J. PARKER, of New York, has gone to Cobalt, Ontario, to take charge of an important mine.

ROY W. MOORE is examining the Artemisa, near San Felipe, in the State of Sonora, Mexico.

V. G. HILLS, of Denver, has been examining tungsten properties in Boulder county, Colorado.

BYRCE TURNER is general manager for the Montgomery-Shoshone Mining Co. at Bullfrog, Nevada.

O. J. REYNOLDS has returned to San Francisco from the Santa Barbara district, in Chihuahua, Mexico.

H. P. GARTHWAITE, general manager of the Butters Salvador Mines Co., has arrived in San Francisco from Salvador.

FOSTER HEWETT, of Pittsburg, is on his way to examine the property of the American Vanadium Co., at Cerro de Pasco, in Peru.

FRANCIS J. PECK has purchased the property of the firm of Crowell & Peck, which has been dissolved. A new firm, Francis J. Peck & Co., will conduct the same business as formerly, with offices in the Williamson Bdg., Cleveland.

Dividends.

On July 5, the Bunker Hill & Sullivan Mining & Concentrating Co. will pay dividend No. 118 of \$180,000. This makes the amount of dividends paid since January 1, \$1,260,000, and total to date \$9,126,000.

Publications Received.

'Contributions to Economic Geology, 1906.' Part 1. Metals and Nonmetals, except Fuels. Bulletin 315. United States Geological Survey.

'The Juneau Gold Belt, Alaska.' By Arthur C. Spencer. Bulletin No. 287. Well illustrated. This most valuable report includes a description of the Alaska-Treadwell and other mines on Douglas island.

'Census of Manufactures,' 1905. Electrical Machinery, Apparatus, and Supplies. Bulletin No. 73, by Thomas C. Martin. Published by the Department of Commerce and Labor, Bureau of the Census, Washington.

A Big Pump.

The largest high-pressure pump in the world is said to be installed in the Dry Diggings placer district in southern Oregon, on Rogue river, and is used to operate a battery of hydraulic monitors. This pump is one of the largest pieces of mining machinery ever manufactured, and could never have been installed but for the fact that it was unloaded directly from the cars to the foundation prepared for it at the mines. The pump was built by the Byron Jackson Machine Works of San Francisco, and was one of the last big installations executed by this company before the earthquake-fire. It is of the five-step centrifugal type, and weighs, aside from bearings and gears, just 70,000 lb. Other pumps have been built that lift as great a volume of water, but they do not deliver it under such enormous pressure as this one. The pump is tested to withstand a maximum pressure of 250 lb. per square inch. It has a capacity of 13,000,000 gal. per 24 hours, or 9,000 gal. per min. This enormous volume is delivered through a half-mile of steel pipe, of 22 in. diam. The water is lifted to a height of 100 ft. and forced through two four-inch nozzles, hurling streams a distance of 500 ft. These powerful streams play upon a high bank of gold-bearing gravel.

General Mining News.

ALASKA.

During this summer the geological survey of Alaska is to be continued by 11 parties, several of which are already in the field. By further subdivision there will be 14 separate groups of explorers, comprising 20 technical men and 21 assistants. Five parties will study economic geology, five will make topographic maps in the Yukon-Tanana, one party will map the Kasaan peninsula, and two hydrographic parties will study the water resources of the most important placer districts. Fred H. Moffit assisted by A. G. Maddron, will examine the copper deposits of the Chitina river, a tributary to Copper river. Much development work is being done in this district.

A settlement has been reached by the mine operators and employees at Ellamar, and the Ellamar Mining Co. has granted the demands of the union for \$4 per day for miners, and has abolished the black list. There is a great demand for miners and laborers at Valdez and Knights island, and 200 more men could go to work at once.—New discoveries of copper ore are being made on Knights island, and 250 men are at work there.—At the Young group of claims on Chickagoff island, two Hendy mills of two stamps of 850 lb. each, have been ordered, and a steam power-plant. A. M. Archangelsky is the superintendent.—Casey & Howard, who bonded the Golden claims from W. P. Mills & Co., are driving on the vein. More miners are needed.

Reports of the good strike at Unalaklik have been confirmed. Roke, Maekle, Spencer, & Gaines made the discovery, after prospecting for two years through the McKinly range and down the Kuskokwim. They have sluiced out some big nuggets and some of the gravel runs 75c. per pan. The Innoko river is 500 miles long, and can be navigated to within 60 miles of the strike with light steamers.—A good deal of prospecting is going on in the Snook region, on the Snook, Boulder, Independence, and Willow creeks, and Cripple river. Good pay-ore has recently been uncovered on Cripple and Boulder rivers.

ARIZONA.

GRAHAM COUNTY.

(Special Correspondence).—The Arizona Copper Co., at Clifton, has just put into operation one of the finest gas-plants in the Southwest, and has just completed a large reservoir above town which will help to supply the concentrator and plant with water. The flume has been repaired and is handling the water satisfactorily. Other improvements are being made and the plant generally is in better shape than for some time past. Judging from the number of improvements already made and the many under consideration, there does not seem to be anything in the recent rumors that the works would soon be moved away from Clifton.—Work will be commenced next week on the new furnace and it will be ready for business not later than July 15.—F. H. Perry, superintendent at the New England & Clifton copper mines for the past four years, has resigned and will devote his time in the future to the development and management of the Laura D mine, on which he has a lease, and from which he has already made two shipments.—In the Standard mines good ore has been encountered and will soon be making a good showing. The best showing is in the shaft of the Copper Center mine, where a good body of high-grade sulphide ore has been opened. The tunnel from the Standard being driven to tap the Copper Center property at depth, has reached a length of 1,000 ft., but up to the present the expected orebody has not been reached. Copper stain is showing in the face of the tunnel, and it is expected that the ore will soon be found. The tunnel has now reached the point where the orebody was expected, but it may be that the vein changed its dip and may require more prospecting to find it. Standard Consolidated stock has been low the past few years, but some sales have been made recently at \$3.

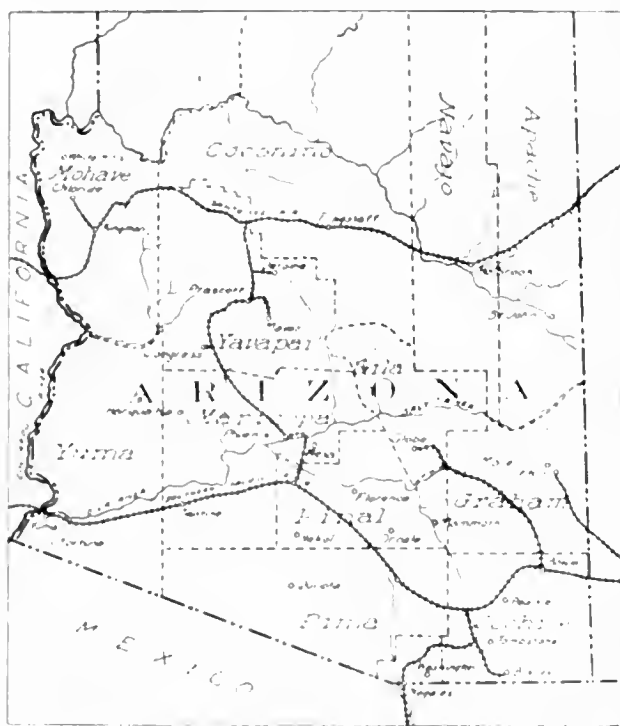

Phoenix, June 22.

Horace Moses is the new superintendent for the New England Copper Co., at Clifton, he having succeeded Mr. Perry, who resigned to operate the Laura D. mine.—I. N. Stevens, superintendent for the Chase Creek Copper Co., announces a strike in the tunnel that cross-cuts the country for 1,750 ft., reaching a depth of 900 ft. The portal is near the Coronado railroad.—A 40-man force is employed at the Gold Belt property, four miles from Morenci. Ore is being hauled, and a 100-burro pack-train will soon be carrying ore. In 15 months the company has done 473 ft. of shaft work, and 796 ft. of tunneling.

The Ash Peak company is not shipping at present, pending the erection of a mill. Arthur Murphy is the manager.—The Gold Belt D. & R. Co. has shipped another carload of ore to the Shannon smelter. The burro-train will soon be packing ore.—The directors of the Shannon company have declared another dividend of 50c. per share, payable July 1.

PIMA COUNTY.

(Special Correspondence).—The work on the Twin Butte mine, near Tucson, has been on the first or 165-ft. level.

Map of Arizona.

From this mine, 12,000 tons of ore have been shipped to El Paso, and it all came from this level. The second level has been opened and connected with the first, but no ore of consequence has been stoped, although there is plenty of it developed. Some time ago it was decided to stop shipping and continue sinking, and opening up the third level. This work is going ahead nicely, and the shipping of ore will be resumed at an early day. With the mine opened in this way, it is expected the working costs will be reduced. The building of a railroad from Tucson to the Twin Butte mine was completed about a year ago, but only recently was the work of surfacing and ballasting the track finished. About 75 men are employed in the mine.

Phoenix, June 29.

PINAL COUNTY.

(Special Correspondence).—In the Kelvin mining district, the London-Arizona mine is looking well. The orebody extends downward at an angle of about 15° and lies along the contact of limestone and quartzite. The tunnel is being run along the top of the quartzite and the caving system will be used in mining. It is a plan of the company to build a smelter on a mesa close to the Gila river, as soon as enough ore is blocked out to justify the expenditure. A gravity-train will be built down to the smelter site, making handling of ore from mine to smelter cheap.

Phoenix, June 29.

CALIFORNIA.

AMADOR COUNTY.

Several men are at work on the Hazard mine, between the Fremont and the Bunker Hill, under the supervision of L. R. Poundstone, who is employed by Lane & Hayward. The Little Amador will start work, also, and Amador City may be lively again. The Little Amador has not been worked for 25 years; the shaft is 800 ft. deep. There was a 40-stamp mill on this property, between the Keystone and the Bunker Hill, and it is understood that good ore was showing in the shaft when work was suspended.

SIESTA COUNTY.

The Delmar smelter will be rebuilt, and will have double the capacity of the old, and be arranged on a different plan. Both old furnaces have been torn down and the converter-room has been dismantled, and an extension will be put on the west end of the building. D. M. Riordan is the managing director for the Bully Hill company.

TUOLUMNE COUNTY.

The Reed gravel mine has been purchased by operators from Alaska.—The Zenora shaft is 112 ft. deep and the vein has widened from 4 to 20 in.—The Blue Lead mill is running, equipped with seven stamps and three vanners.—Some rich ore has been struck on the 170-ft. level of the Duffield.—Sinking at the North Star will be resumed this month. W. G. Phipps is the manager.—Work on the new 100-stamp mill for the Grizzly, Dead Horse, and New Albany properties is progressing rapidly. These mines have produced large amounts of gold.—About 20 men are employed at the Spring Gulch mine, and new equipment is being installed.—The Eagle-Shawmut company, which is operating an 80-stamp mill, is arranging to have a spur built from the Yosemite Short Line railroad to the mine.—Marble quarrying machinery is being installed at the quarry near Vallecito, and 100 men will soon be employed.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—Reports of a strike in the 850-ft. tunnel on the Orofino mine, six miles east of Murray, have come to Spokane. The vein was encountered a few days ago and proved to be nine feet wide. Two feet of the lode is shipping ore, which carries 35% lead and some silver. The rest of the vein is concentrating ore. The strike was made at a depth of 165 ft. There is some doubt as to whether it is the Orofino vein that has been cut, for, according to surveys, the vein should lie about 40 ft. ahead of the present breast of the tunnel. A drift will be run 100 ft. each way, and then a shaft will be sunk. The Orofino is the west extension of the Bear Top mine and is held under bond by Missoula men, represented by M. R. Rutherford. One payment has been made on the bond and others come due in October and April.—The Hecla Mining Co. has paid a dividend of 10c. per share, or a total of \$100,000 for June. This brings the Hecla's dividends for 1907 to \$280,000, and total dividends of \$1,280,000 to date.—The Hercules Mining Co. has paid its regular dividend in June of \$92,000, bringing the total this year up to \$572,000. The grand total to date, including the present dividend, is \$2,392,000.—W. D. Greenough, manager of the Snowstorm mine, near Mullan, says the company will soon increase its dividends. He says they are getting \$98,000 per month from the smelting company for ore shipped and are only giving out a dividend of \$45,000 per month. At present they have under way improvements to the amount of \$50,000 in bunk-houses and boarding houses. The orebodies are opening up in good shape and the Snowstorm mine will be one of the large copper properties of the country within the next two years. Shipments are 400 tons per day, but lack of labor is the only thing that is holding down the production to this figure. The company paid its regular monthly dividend of \$45,000 in June. This brings the dividends for this year to \$315,000. The company has maintained its rate of three cents per share for five consecutive months.—Work will begin soon on a concentrator for the Moon Gulch M. Co., in Moon gulch, in the Coeur d'Alene. The property consists of six claims. The lower tunnel on the property is in 480

ft. The capital was recently increased from 1,000,000 to 1,500,000 shares. A carload of ore has been shipped.—W. W. Wait and David Cross, of the Temple Mining Co., have made arrangements to finance the Rob Roy M. Co. in the Coeur d'Alene. At a meeting of the board of directors a few days ago, the resignation of McInnis, president of the company, was accepted, and these officers were named: President, Sam D. McDonald; vice-president and manager, J. N. Davis; treasurer, Hugh Toole. W. W. Wait has been elected secretary of the company in place of O. A. Olsen. The property consists of five claims in the Sunset Peak district, and development work has been carried on for 12 years. The property has been developed by two long tunnels and some shaft work. There is a well defined vein, and good ore has been exposed. The company is capitalized at \$1,500,000. Work is to be resumed at once under the management of J. N. Davis, and orders have been placed for ore-cars, tracks, supplies, and equipment.—W. Clayton Miller, of the Federal M. & S. Co. (of which Charles Sweeney, of Spokane, is president) states that within two years no mill in the Coeur d'Alene will be producing coarse tailing. The re-grinding machinery will be in operation at the Morning mill before the snow flies and from that time on the mill will discharge nothing but slime. Re-grinding machinery will be installed in all other mills of this company. The closer milling will not only increase the district's output, but it will be a material factor in solving the tailing problem.—Directors of the Reindeer Copper M. & M. Co., operating in the Coeur d'Alene, have resigned and a new board has been named. The new officers are H. A. Keough, president, and J. B. Wilcox, secretary and treasurer. The reason for the resignations is that it cost the company \$50 per foot to sink a shaft on the property, an expense it could not bear. The new board has levied an assessment of one cent per share to carry on development work, and it is now planned to run a lower tunnel of 4,000 ft. to tap the ore. This will cost \$50,000.—Directors of the Missoula Copper M. Co., which owns a group of claims on Snowstorm hill, near Mullan, will award contracts soon to drive an 1,800-ft. tunnel to tap at depth the two veins crossing the company's ground. The work will cost \$20,000.—Work has been started on the 100-ton concentrator at the Stewart mine, near Wardner. The Stewart has been shipping steadily the last two months, the ore being forwarded to the smelter at the rate of 20 tons daily.—The Federal M. & S. Co. paid its regular quarterly dividend of \$510,000, June 15. The common stock obtained \$300,000 and \$210,000 was divided among the holders of the preferred stock. This makes a total of \$1,020,000 disbursed this year and a total of \$5,650,000 to date.—S. P. Williamson has just returned from the Pittsburg group, on which he recently took a \$100,000 bond. Work is being done on the tunnel preliminary to employing a larger force of men. The group is one of the oldest locations in the Pine Creek district in Idaho. It was located by Gus Smith, of Wardner, and is owned by him. It adjoins the Nabob, and is believed to have the same vein. Ore has been found in the tunnel, which is in 200 feet.

Spokane, June 29.

WASHINGTON COUNTY.

Reports state that a rich strike has been made by the Belmont Mining Co., in the Heath district. This company was organized but a few months ago and the stock is owned by Weiser and Boise people. E. M. Heigho is president and Avery C. Moore is treasurer.

MONTANA.

FERGUS COUNTY.

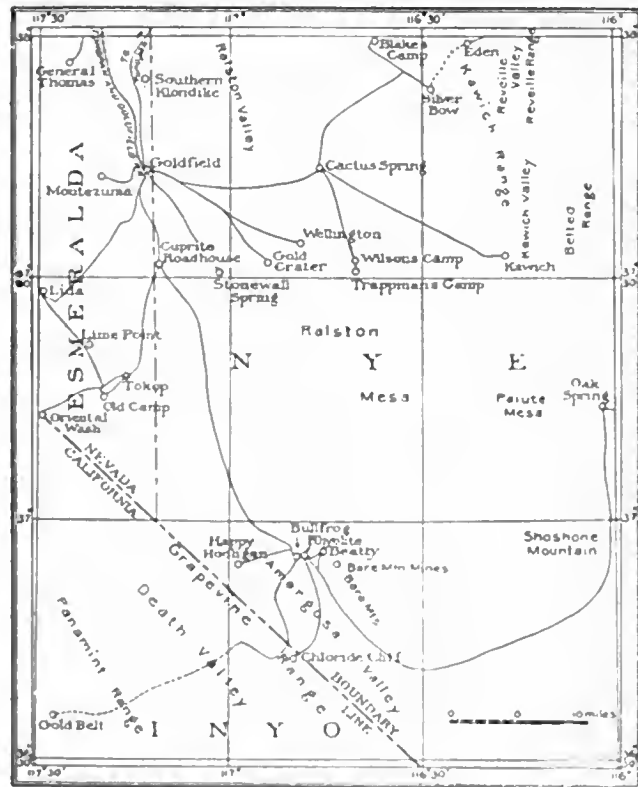

The Barnes King Development Co. is capitalized at \$2,000,000, divided into 400,000 shares par value \$5 each. The Barnes King property is in the Kendall district, which is the largest gold-producing district in Montana. The gold-bearing veins have been worked at different points for two miles in length on the veins. This property consists of 23 mining claims, composed of 200 acres of ground, equipped with a mill of 210 tons daily capacity. The mill has produced, since starting, more than \$1,700,000 in gold bullion

from Barnes King ore. The method of extraction is by cyanide, and is simple and cheap. The Development company bought the Barnes King property January 1, 1907, and immediately started development and equipment work on a new machine shop, new air-compressors, and a new shaft at the south end of the property. Part of the new machinery has already arrived at Lewistown. About 1,000 ft. per month of development, drifts, and tunnels have been run in the mine, and in doing this work a new vein parallel to the present workings has been discovered and opened up. This is the most important discovery of ore made in the history of the Kendall mining district, as the ore assays from \$10 to \$24 per ton in gold, and has been opened by drifts and cross-cuts, showing a body 25 ft. wide and 400 ft. long.

NEVADA.

LANDER COUNTY.

(Special Correspondence).—The Bullion Transportation Co. has been organized to carry freight and passengers from

Part of Nevada.

the Southern Pacific at Beowawe to Tenabo, 25 miles. Fifty men are engaged in the construction of a first-class road. This company now has at Beowawe a 60-h.p. traction engine for freight, and two automobiles. P. B. Locker is the president.—The telephone line from Beowawe has been completed and is now in operation.—The Nevada-Phoenix M. Co. has installed a 25-h.p. gasoline hoist and is down to the 200-ft. level, and is shipping two carloads of ore per week.—The Little Gem Mining Co. has a two-drill compressor in place. A pump has been installed, as water was encountered on the 300-ft. level. This mine has been a steady shipper for the last 10 months.—The Gold Quartz M. Co. has its new 15-h.p. hoist in operation, and is sinking the main shaft, which has reached the 200-ft. level, encountering at that point vein-matter in the granite. They are shipping from the 100 and 30-ft. levels ore running well in gold and silver. The Riggs lease on this property continues in ore, and is a steady shipper. Twelve tons of good ore is sacked and ready for shipment.—The Pocatello-Nevada M. Co., of which John Toombs is president, has reached 150 ft. in the shaft with a whim, and is cross-cutting to the vein. This company owns the Dexter, Pauline, Jack Rabbit, and Two Johns claims.—The Widows mine is one of the best of the smaller producers. A shaft is 100 ft. deep on the incline, following the vein. The ore from this property averages \$70 per ton. P. B. Locker

and T. Raleigh are interested in this company.—The Grand Victor, Great Western, and Vollante claims, adjacent to the Gold Quartz, were recently purchased by the Nevada Hills company. Machinery is being installed for development work.—The town of Tenabo is growing rapidly, and miners and carpenters are in demand.

Tenabo, June 28.

LYON COUNTY.

(Special Correspondence).—A strike is reported on the third level at the Ramsey-Comstock mine, the pay-shoot being on the hanging wall, where it is wider than on the second level. Picked samples ran \$500 per ton. There is not as much copper showing in the ore taken from the cross-cut as is found in the drift above, but more of it is showing as they drift north on the shoot. The conditions on both levels are almost identical and it is quite evident a few feet will uncover rich specimens of gray copper ore. When they drive about 35 ft. a raise will be run to the next level. The ore pans free gold, along with the rich sulphides.—Another high-grade find has been made at the Ramsey-Consolidated mine, locally known as Dago No. 2. The company is sinking the shaft outside the hanging wall and has encountered some ore. This one is about 3 ft. wide and contains gray copper, gold, and silver. Nearly 3 oz. gold, 7 oz. silver, and 3% copper, or \$58 per ton. Finding gray copper in this parallel vein calls attention to the strike, as this mine is on a belt separate from the Ramsey-Comstock, where the same character of ore was found.

Another strike was a cross vein encountered at the 150-ft. level. They have encountered water in the mine; the shaft is 270 ft. deep and will be continued another 30 ft. before cross-cutting is done.—At the Ramsey-Bonanza mine, ore has been struck in two places in a cross-cut being driven from the lower incline shaft to the vertical working shaft. The first strike is quartz, occurring near the hanging wall accompanied by a talc seam 18 or 20 in. thick. The second strike was made a few feet further on, in an ore carrying sulphides. They are now sinking again in the shaft and are down about 70 ft. from the surface, and will go 500 ft. deep.—At the old Garavanta mine they have encountered the hanging wall of the great dike, known as the Mother Lode, and have found ore of low grade, with some milling ore exposed, although at intervals are ore-shoots of shipping value. Near the hanging wall of the porphyry dike they have found a vein five feet wide that is richer than any so far encountered. The strike occurred at the end of the 650-ft. tunnel. Above this tunnel two more are driven, each over 400 ft. long, and showing ore. Farther up the ravine two incline shafts are sunk on either wall of another parallel vein. At this point a cross-cut was run 80 ft. toward the hanging wall, on the 120-ft. level. Water drove the workers out, but they are arranging to put a pump and hoist in and will soon be at work on this part of the property.

Ramsey, June 20.

SAGE COUNTY.

At Manhattan, a little work is being done on the Seyler-Humphrey ground by lessees, but not by the company itself, as there are no funds and the treasury stock is exhausted. The company must raise more money in some way, and a scheme for reorganization is being planned. This was one of the typical Manhattan stock flotations, which sold shares at a good price during the boom, but now the inevitable slump has come.—The Manhattan Mining Co., operating the Annie Laurie claim, has recently suspended operations, owing to lack of funds. The Manhattan Homestake Co., also managed by Bond & Co., closed down several weeks ago.—It is reported that operations may be resumed on the Manhattan Buffalo, but the property is idle at present.

NEW MEXICO.

GRANT COUNTY.

Santa Fe engineers have surveyed a line for the proposed extension into the Burro Mtn. mining district. This line will be 14 miles long, and will leave the Silver City branch a short distance above Whitewater, running up a cañon to the Tyrone property and to the Burro Mountain company's mines, and serving the Comanche, Copper Gulf, and other properties in the neighborhood.

LINCOLN COUNTY.

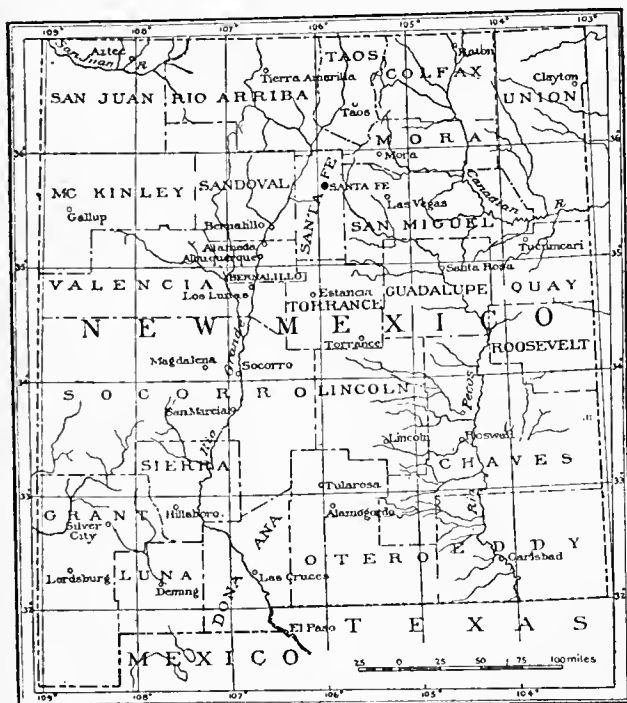

Three companies are working in the Red Cloud mining district, which was a producer of some gold, silver, and copper ore, 20 years ago. The principal companies are the Corona Queen, of which Thomas M. DuBois is superintendent; the Columbia Copper Co., of El Paso, with Martin Fishback in charge; and the Iron & Copper Co. of Denver, for which J. Morris Finn is the manager. Steam-hoists, pumps, and other machinery has been ordered for all these properties. There are 200 men employed in the district.

OTERO COUNTY.

The Tularosa Copper Co., operating at Bent, is turning out concentrate from its 30-ton mill. Plans are being considered for a larger plant. The main shaft is down 75 ft., but stoping has been carried for 300 ft. each way on the vein. The company operates with water-power, supplemented by steam.

SAN MIGUEL COUNTY.

Development work on the copper mines of the Pecos Mining Co. has ceased for the present, and the miners have

Map of New Mexico.

been laid off. The company, for which O. W. Alexander is the superintendent, is considering the construction of a branch railroad from the mines to the Pecos switch on the Santa Fe railroad, 23 miles.

OREGON.

BAKER COUNTY.

L. V. Swiggett announces that a mill will be built on the Golden Chariot ground. It will consist of four batteries of three stamps each, of the Merrill make.—The dredge at the Crane Flat placers has been closed down by A. Burch, and no more work will be done at that point.—About 15 men are employed at the Bonanza mine, and development is progressing beyond the dike on the 200-ft. level.—The Daines M. & M. Co., operating the Belcher mine in the Greenhorn district, will build a mill this summer, and install machine-drills.

SOUTH DAKOTA.

CUSTER COUNTY.

(Special Correspondence).—The largest operating company here just at present is the Westinghouse Electric Co., and is working two mica mines, the New York and the White Spar, where 35 men are employed, besides the 50 operators that work at the mica factory at Custer. They are just now putting in an electric plant at the New York mine, with an engine of 250 h.p., weighing 16 tons. Joseph Pyne is in charge of this property.—One of the busiest camps

in the district just now is the Saginaw, where the company is driving from the 400-ft. level and at the same time erecting a mill of 100 tons capacity. They have a vein 12 ft. wide of \$10 ore and two other veins, one on each side, each about 7 ft. wide. They have not yet been reached in the drifts from the bottom of the shaft. The company has recently purchased the Philis and Solon groups of claims, which adds 160 acres to their holdings of 21 claims in the district. I. B. Herber is the manager and 25 men are employed.—On the Catawassa group, situated about nine miles northwest from Custer and near the Saginaw, Dan McGonigal and J. Hazlett are opening up a promising prospect. They are down 30 ft., and employ 10 men, running two shifts.—The Niagara is situated about 12 miles north of Custer. The company is sinking on a nine-foot vein of gold ore. About ten men are employed at this mine.—The Ivanhoe group of mines, eight miles east of Custer, with its five-stamp mill, is running steadily and the company is developing extensively.

Custer, June 25.

LAWRENCE COUNTY.

The incorporation of the North Homestake Mining Co. has been completed, with a capital of \$6,000,000, divided into shares of \$5 each. The company was organized under the laws of South Dakota, and has filed articles in Illinois so that it can have an office in Chicago. The organization took over the Penobscot group, formerly known as the Maitland mine. The officers are: Alexander Maitland, president; James Root, secretary and treasurer; A. J. Plowman, F. R. Baldwin, and E. W. Miller, directors. A wet-crushing cyanide plant with 40 stamps is in operation, the mill having been built several years ago by Cyrus W. McArthur, of Denver. The plant can treat about 150 tons per day, the ore averaging about \$7.65 per ton, with an extraction of about 72%. As the cost of mining and milling is reported as \$3.31 per ton, this would only leave a net profit of \$2.20 per ton, or \$100,000 for 300 working days, which would be only a fair profit on a capitalization of \$1,000,000, so it is apparent that some change must be made in the process or equipment before the capitalization of \$6,000,000 will be justified.—The fire in the Homestake has been extinguished, and the work of unwatering the workings has commenced. The mine had been allowed to fill to a point 75 ft. above the sill floor on the 300-ft. level, and the water above the 300 level is being drawn through valves placed in the bulkheads in the North End and Savage tunnels, whence it goes into Deadwood and Whitewood creeks. The skips will be started as soon as the water sinks to the 300-ft. level. The DeSmet mill is running with 100 stamps, and the Highland with 240 stamps, the ore being mined from the Star and DeSmet open-cuts. There are 200 miners at work and as soon as mining is started in the Terraville cut, the Monroe and Pocahontas mills will be started, adding 260 stamps to the 340 now dropping. The cyanide plants are working.

PENNINGTON COUNTY.

Machinery for the new electric hoist at the New York mica mine is being installed.—The Auburn mill, at Mystic, has started, and it is said that there are 3,000 tons of ore on the dump averaging \$7 per ton. The capacity of the mill is 75 tons per day.

TEXAS.

EL PASO COUNTY.

Seven of the eight furnaces of El Paso smelter are shut down as a result of a strike of 160 scale men, who walked out because they were not given the raise in pay demanded by them. The strikers are all Mexicans, who have been getting \$1.20 per day of 12 hours, and a premium of 20c. per day when working 25 days consecutively. The men have demanded a wage of \$1.50 flat, per day.

WASHINGTON.

CHELAN COUNTY.

(Special Correspondence).—On Chelan butte a vein nine feet wide has been intersected in a cross-cut, at a depth of 30 ft. There are other new discoveries on the butte. The Red Mountain mine, reputed to be one of the richest copper properties in the Cascades in eastern Washington, has

been visited by some of the directors of the company from New York, who have stated that a railway will be built 26 miles, from the mine to the Great Northern railway, and that the company will ship to the Tacoma smelter, until a smelter, now under construction by the company at Index, Snohomish county, is completed.

Republic, June 26.

FERRY COUNTY.

(Special Correspondence).—The Colville M. & S. Co., a New York corporation, has purchased three claims in Belcher district, named by the company the North Half group, and 42 claims in Park City Camp, known as the South Half group. An average sample from an iron-capped vein on this northern group assayed \$7.20 gold and 1.3 oz. silver per ton and 37.5% iron. Another vein was lately discovered, from which samples assayed well. An adit has been driven 260 ft. to cross-cut these veins, and the face is now in quartz, but has not reached the foot-wall. An Ingersoll-Rand Davis-Calix core-drilling outfit has been sent to the property, and a bore from the surface will be used to test the veins to a depth of 500 ft. On the South Half group 42 men are employed, and extensive operations have been planned. The county road up Gold creek has been improved, and a private wagon-road therefrom, 7,000 ft. in length, has been completed. A survey has been made for a water motor and electric power-plant and smelter site, and the company has contracted for three Ingersoll-Rand drills. From the Mountain Boy, one of the company's claims, the last carload of ore netted about \$1,100 over the freight and treatment charges, and three carloads are nearly ready for shipment on which the management expects to realize a net profit of \$1,000 per carload. Some low-grade ore will be treated by smelting in the two Medberg furnaces now in transit. From the north side of the hill an adit is being driven which intersected one vein at 110 ft. and another about 200 ft. from the portal. It is in 390 ft. and is expected to cut the vein on the south side at about 200 ft. further in. Six test pits have been sunk, and the vein has been stripped along the strike of the Summit vein for a distance of 120 ft. An average of 10 assays of the ore was \$1.60 in gold and 385 oz. silver per ton. The Summit vein varies from five to seven feet in width, and the filling is mostly quartz. An adit is being driven to cut it about 200 ft. deep. Another adit is being driven by this company to cut the Honest John, Alexander, Washington, and Blue Bird claims. Three cabins are under construction, the millsite is being cleared, and 4,600 ft. of flume is being built, to take water from Gold creek to the smelting and electric works. G. Weaver Loper is the general manager.

The Oversight M. & M. Co. has reported success in using a dip-needle for the discovery of ore deposits under the debris which covers the several veins on the Oversight group of claims. By this means a vein of iron sulphide ore has been discovered on the Granite claim, west of the No. 3 Oversight adit. The ore has a little quartz gangue. The vein has been traced for 140 ft. and found in three places, where it was covered only three or four feet with debris.

Republic, June 26.

OKANOGAN COUNTY.

(Special Correspondence).—The Oroville Consolidated Mines is a company recently incorporated, with \$2,000,000 capital stock, to develop property on the Okanogan and Similkameen rivers and Kruger Mtn. The trustees are W. C. Hancock, E. W. McAmmon, Riley Coyle, A. Signs, and W. S. Schlensker.—The Grant Consolidated Mining Co., at Chesaw, has 25 men employed under A. D. McPhee. The last returns of ore shipped to the Granby smelter, at Grand Forks, B. C., approximated \$1 gold per ton and 6% copper. A new adit, to be run 1,500 ft., is expected to cut three different veins at depths of 300 to 500 ft. It is hoped to have 200 ft. of it driven this month.—The Standard mine, in Meyers Creek district, is being put in shape to ship ore, of which there is a good showing in the upper workings. The principal value is in copper. The company is figuring on a new adit about 1,200 ft. long, and in the meantime will drive the present lowest adit about 250 ft. farther to cut the vein.—The Crescent group of claims, in the

Twist district, has been bonded to Spokane people, who are obligated to work them continuously during the life of the bond, which calls for \$50,000.

Republic, June 24.

SPOKANE COUNTY.

Moran prairie, five miles south of Spokane, may develop the only real tin mine in the United States. Arthur J. Collier, an expert in the employ of Government geological survey, is now in Spokane and has spent several days looking over the property of the Spokane Tin Mines Co. He was reticent regarding the results of his investigation of the mine, but estimated that it is promising. He said the country about Moran prairie possessed geological formations such as would be found in a tin-producing country. The fact that there is granite in the land is rather favorable and an indication that the property is at least a good prospect.

STEVENS COUNTY.

Under the superintendence of L. Larsen, the Trojan M. & M. Co. has resumed work on its property on Toulon Mtn. After striking ore in an adit, 180 ft. below the cropping, a winze was sunk, but water drove out the miners and work was suspended. The company is driving an adit, expecting to encounter the vein at a depth of about 50 ft. and 800 ft. from the portal. It is expected to cut two other veins.—The First Thought Mining Co. is now shipping ore having a gross value of about \$40 per ton, chiefly in gold. There is sufficient ore reported as developed to maintain a monthly production of 5,000 tons for five years. At 500 ft. from the portal of the main adit a station 80 ft. square was excavated, and a 60-h.p. gasoline engine was installed. At 170 ft. below the adit a cross-cut has intersected 27 ft. of ore. An aerial tramway, driven by a 20-h.p. engine, was constructed at an approximate cost of \$30,000 and conveys the ore from the adit, two miles to the Washington & Great Northern railway, for shipment to the Granby smelter. The tram is capable of handling 250 tons per day.—The Sunset mine, near Northport, is producing ore which assays about \$100 per ton in gold, silver, and antimony. The shaft is down 210 ft. and will be sunk 100 ft. deeper. It is equipped with a hoisting and compressor-plant.—At the Mammoth and Morning mines, in the Metalline district, a joint adit is being driven between the two properties which has cut a 24-ft. quartz vein, rich in galena. It will be driven another 100 ft., to another vein, which crops out further up the hill. On the first vein the adit gives a depth of about 150 ft., and on it a winze will be sunk.

Republic, June 27.

MEXICO.

SINALOA.

The San Miguel Mining & Reduction Co. has been incorporated by a number of Denver railroad men and it is their intention to operate in the Santa Lucia mining district in the State of Sinaloa, where they have secured a large tract of land. Hugh Swearingen and Frederick Matthews are at the head of the concern.

SONORA.

At Cananea, spontaneous combustion in a planing mill started a fire that destroyed the assay-office, machine-shop, and a portion of the supply department of the Cananea Copper Mining Co. The smelter was uninjured, and the loss of \$150,000 is covered by insurance.

Reports state that within the last few days ore has been opened in shaft No. 7 of the Cananea-Bisbee company. At the 250-ft. level, the east drift has encountered good ore.

NICARAGUA.

The new Nicaraguan mining code seems to meet the approval of all interested; by its terms miners are allowed to import everything required for the mines free of duty. Almost the entire mountain country is virgin land open to location, and, while one Pittsburgh company has a mineral grant covering almost the entire district, they now grant prospectors terms which are almost as favorable as could be obtained from the Government.—No known coal or oil exists in the district, but the multitude of small streams, with falls and rapids, makes possible the use of hydro-electric plants for power purposes.

Special Correspondence.

London.

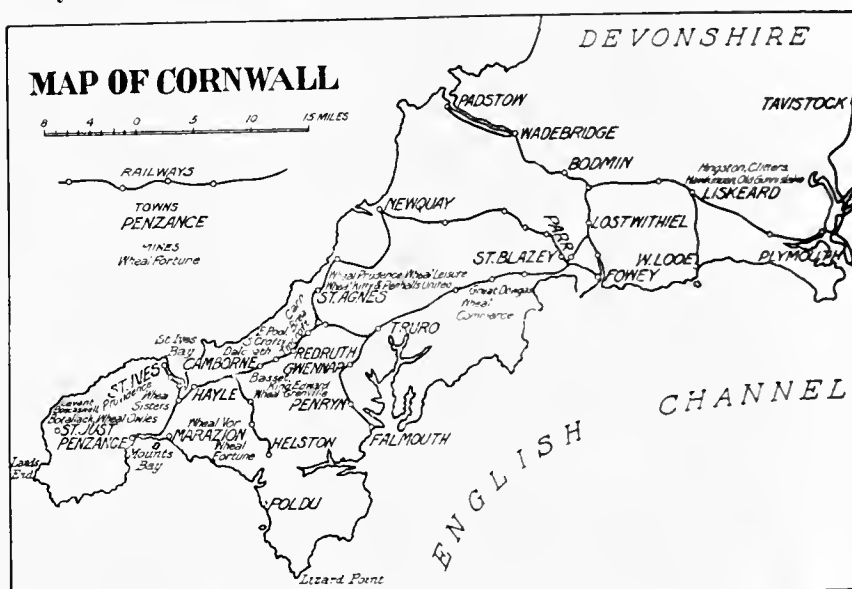

**Cornish Tin Ticketing.—Style of Reports.—Reopening of Old Mines.—
Comparison with the Rand.—Rhodesian Gold Production.**

The last Cornish black tin 'ticketing' showed a welcome increase over the previous fortnightly sale to the extent of some 40 tons in quantity and £4,000 odd in value. The total (244½ tons) realized £28,869, an average of £118 per ton. The chief sellers were: Dolcoath, 70 tons; Basset, 30; Carn Brea, 29; Grenville, 27; East Pool, 24; West Kitty, 14; Levant, 12½; Clitters 9 tons, and four of the resuscitated mines including Botallack and South Crofty made a brave show, with a few tons each as a beginning. The sale at Redruth attracted several strangers, among whom were Capt. Richard Cowling, for many years the manager of the Hamley and Yelta mines, Mr. Richard Eustice, chief engineer and surface manager of the Moonta mines in South Australia. These gentlemen had been absent from Cornwall nearly 40 years. As if to illustrate your correspondent's remarks on the subject of mine reporting, 'A Somerset man,' writing to a London journal asks, "Does the Cornish revival continue? We seem to hear very little about it. Are the new mines meeting with any success? What is the state of their developments? I suggest that they should issue short monthly reports. We do not want long ones with elaborate details, which no one reads, and few people understand if they do read, but we want a synopsis of what is being done and what is likely to be the result. I take a

great interest in Cornish affairs, but must say I am not well informed as to what is going on for the simple reason that official news does not seem to be forthcoming." Evidently the gentleman in question does not read the mining papers or he would have discovered that some, at least, of the Cornish mines are not backward in giving an account of themselves. Here is a specimen from South Crofty. "Report for four weeks ended June 8: Robinson's shaft—The pumps are completed to the 60 fathoms balance box station. Bickford's shaft—Recent developments near Bickford's have been important. It is probable we start equipment of this shaft at an early date. New Cook's Kitchen shaft, 18 by 6 ft. within timber, is 75 ft. below collar. Seven stopes are being worked by 46 men on day shift. Footage for the month, 255 ft. We have commenced to take out the Cornish stamps. The 20 Californian stamps crushed 1,378 tons for 22 tons tin and wolfram. Average recovery, 35.76 lb. per ton. We expect to have 40 heads working in July. Buss tables and Luhrig classifiers are working satisfactorily. Tin sold, £1,444; arsenic sold, £977. Recovery of arsenic per ton of ore was 12 s. 4 d. Wolfram—tenders for approximately 10 tons (60 to 70% tungstic acid) will be received on Monday, June 10." Another report states that the Californian battery is doing most excellent service. Over three tons per head are being crushed, and when the rock-breaker is at work the mill will render still better service. Those who have not fully appreciated the potentialities of Crofty are wondering where the tin-stuff is to be obtained to satisfy the

hungry maw of a mill of 40 heads. The bulk of the ore up to now has come from development, but over 2,000 ft. are now available for stoping, and some 50 men are engaged on this work. The Buss tables—six of them—are now in service and are giving good results.

An interesting function has recently taken place in the cutting of the first sod of a new shaft to re-start the Rodney mine at Goldsithney, in West Cornwall, a property well known to older residents of Goldsithney and district, and some of them are ready to say that it will become the best mine in the County. The work is being taken in hand by the Cornish Tin Syndicate. One of the speakers on the occasion of the ceremony said they were commemorating that event upon the day in which the greatest gamble in England took place—Derby Day—and he trusted that Rodney would prove a good horse to those who had backed it. The manager, Capt. Sam Williams, informed the company that he had known the property over thirty years. It had four lodes, which all joined to the east of the property, going right through to the west,

and they were from 3 to 20 ft. wide, and averaged about 40 lb. per ton. There were five working shafts on the property. Another old property to be re-opened is the Basset & Grylls, in the Wendron district, for which a company has been registered as Basset & Grylls with a capital of £12,000, in £1 shares. The first directors are Messrs. C. V. Thomas, O. Wethered, G. B. Pearce (all connected with Dolcoath), and W. J. Payne.

In an able article on the labor question the *Cornish Post* points out that there is no comparison between the condition of the Transvaal gold mines and the Cornish mines. In the first place, before one of the deep Transvaal mines reaches the producing stage a million pounds sterling has to be spent. The size and value of the reef is known. Arrangements are made for handling enormous tonnage. In Cornwall the lodes frequently vary in size and quality, and there are many lodes and many surprise packets in store for shareholders. Also no one subscribes a million capital and waits four or five years for returns from a single Cornish mine. Then again, the Transvaal mines are practically dry, whereas Cornish mines are so wet that each mine spends a fortune in pumping charges. No comparison can be made between Rand tube-mills, and cyanide process, and the stamps, vanners, tables, and frames used in dressing Cornish tin. Not only so, but one Cornish mine cannot even be compared with another, because a dozen factors may be different even in two neighboring mines. The one may have complex, the other free-milling ores; the one may have a larger area for its dressing plant than the other; the one may have

ample capital, the other may be slowly getting out of a tangle due to a shortage of capital or a score of other difficulties in times past.

According to a Reuter cable, on June 14, in the Transvaal Parliament, Gen. Botha confirmed the statement that the Chinese would be sent home on the expiry of their contracts. The Government was actuated by the fact that the native labor supply had for some time exceeded the demand. Repatriation is to proceed as the indentures expire to the number of about 16,000 before the end of the present year. This announcement had a depressing influence on the Katfir market.

The Rhodesian gold output for May is returned at 52,668 oz., which is 2,541 oz. above the previous record established in August 1906. This makes the aggregate for the first five months of the year 236,857 oz., an increase of 22,344 over that for the corresponding period of last year. The other minerals produced during May comprised 12,730 oz. silver, 66 tons of lead, 10,148 tons of coal, 7 tons of copper, and 56 tons of chrome ore, while from the Broken Hill mine, in Northwestern Rhodesia, 250 tons of ore, assaying 55% zinc, were produced.

Johannesburg, Transvaal.

A Big Strike.—Riot and Disorder Soon Stopped.—Enforcement of Law.—The Engine-Drivers Uncertain.—An Opportunity for the Afrikanders.

It has come at last. No one ever expected to witness a strike of such magnitude on the Rand, but here we are in the midst of the greatest industrial upheaval ever known in South Africa. To the men who have gone out the results will be rather disastrous, from the wage point of view, but to the mining industry the strike will prove a blessing in disguise. With the exception of the mines controlled by J. B. Robinson, there is now a general strike along the Witwatersrand, in response to the orders of the Transvaal Miners' Association, ordering all underground men to leave their work. Why J. B. Robinson's crowd is exempt is not definitely known, but the general opinion is that he bought peace by donating £10,000 to the strike funds. The Government has acted with surprising promptitude and wisdom. The strikers raised hell on two mines, the Robinson and Robinson Deep, for a day, when several heads were hit, and some property damaged. After this, the Riot Act of 1894, which forbids an assembly of more than six persons within 300 yards of any mine shaft, mine building, etc., was promulgated, and Imperial troops were dispatched from Pretoria to see that law and order was maintained. Had not the Government acted with such firmness, and had the strikers continued to think that the supposed sympathy of the Government would have allowed them any latitude, there is no doubt that ere this many lives would have been lost and much property destroyed.

Seldom, if ever, has a strike of such magnitude been carried on, with so little bloodshed, or destruction of property. Had the same thing occurred in any place in America, especially in the Western States, long before this there would have been many disgraceful and brutal acts. Would that the same reign of law and order existed in the mining regions of the United States as one finds in the places where the Union Jack flies. There can be no doubt that in the British dominions there is much less chance for riot and anarchy during a strike than we find in the Great Republic. Why this comparative law and order on the Rand? Firstly, because the citizens of this place, both strikers and non-strikers, have been brought up to a wholesome regard for the law. Then again the military and police forces have been

used promptly, without any regard to the political consequences. How often in America has the party in power refused to use the strong arm of the law for fear of losing the votes of strikers later on!

The hoisting-engine drivers on the Rand are the most important factor in the present dispute. They have a strong well organized association and desperate efforts are being made by the Miners' Association to induce them to join the strike. So far the drivers have refused. A ballot is to be taken this week, however, and every one is awaiting the result with the keenest interest. As it requires two-thirds of the membership of the Engine-Drivers' Association to declare for a strike, the chances are against it. Should they come out, it will be a serious blow to the mines, for there is a limited supply of engine-drivers, who must be certificated by law, before they can haul men. No matter what happens, however, the mining houses are determined to see the strike to a

Map of the African Goldfields.

successful issue, even if it means shutting down many mills. The managers feel very sore over the strike, for they maintain that the underground men had absolutely no cause for the action they have taken. If the engine-drivers remain loyal to the companies, the strikers will undoubtedly lose the day. When they return to work they will come back on quite different terms. The days of the huge salaries for men who simply superintend labor are over, and we shall not hear again of miners earning from £75 to £100 per month. Day's pay will be the order of the day, and more shift-bosses will be put on to see that the day's pay is really earned. Hand stopers will earn from 16s. 8d. to 18s. 4d. per shift, and machine stopers from 20s. to 25s. per shift.

The present is a great opportunity for the Afrikanders, and they fully realize it. In the past the miners have tried to keep the underground work more or less to themselves, so that today the percentage of white men working in the mines, born and raised in this country, is rather small. This will be changed now. Boers from the farms are gradually coming in to the mines for work. Of course, they know little about mining, but as they are strong healthy men, amenable to discipline, they are good material to start with, and will in time make good

miners. To break these raw recruits in will require some time, and possibly some stamps will be hung up for awhile, but the general feeling is that it is better to suffer a bit just now, and teach the mining work to a class of men that will always live in the country, and who are not always grumbling.

Butte, Montana.

Assessments for Exploratory Work.—The Colusa-Leonard Extension Co.—Reins Copper Co.—Discovery in the Greenleaf.—Deepest Shafts.—Teamsters Strike.—Talk of Another Smelter.

It seems likely that a number of the new mining companies operating in the Butte district will follow the example of the Amazon-Butte Mining Co. and make their stock assessable in order to raise money with which to continue development work. The Amazon-Butte assessment of five cents per share was promptly paid, stockholders preferring to pay it rather than permit treasury stock to be sold at the present low condition of the market. The Park Copper Co. has sent a circular to its stockholders asking for written permission to make the stock of that company assessable, the consent of three-fourths of the stockholders being required under the law. This company proposes an assessment of 2½c. per share, to create a fund of about \$15,000, which, the directors believe, will be sufficient to carry the development work to completion. An effort was made to pool the outstanding stock of the Park company, but less than one-tenth of the stockholders responded to the appeal. It is frankly stated in the circular that unless the stock is made assessable it will be necessary to stop work, and that would mean the death of the enterprise. It is hoped that by the time the first assessment is spent the mine will be able to pay its way, as some ore has been found in the vein so far explored.

The Colusa-Leonard Extension Co. is having trouble in handling the water in its shaft, as the old shaft of the Sinbad, a short distance east of the Colusa-Leonard, is draining the latter. The Sinbad is about 500 ft. deep and was filled with water. The Colusa-Leonard is now something over 720 ft. deep. The company's pumping capacity is taxed and additional pumping machinery has been ordered. It also is the intention to get new hoisting machinery, as the engine is not of sufficient capacity to sink to the depth of 1,500 ft. as contemplated. —The Reins Copper Co. is now making regular shipments of copper ore from the Combination mine. The ore comes from the 900 and 1,000-ft. levels and averages about 6% copper. The physical condition of the mine has been gradually improving.

The strike of a small vein of rich copper ore in the Greenleaf mine by the Boston & Montana Co. has raised the spirits of the men that are developing properties on the east side of the Butte district. The Greenleaf is situated only a few hundred feet south of the Six O'Clock mine, which was abandoned by the Butte Exploration Co. because pay-ore was not found in the first cross-cut. The vein was cut in the Greenleaf shaft at a depth of 840 ft., and from a little seam it widened in about 10 ft. to a thickness of 14 in., carrying bornite and peacock ore, assaying as high as 30% copper. It is considered an important strike, as it seems to demonstrate that the ground to the east of the Butte hill offers the same chances as the hill itself, and that the Butte Exploration quit too soon. The Greenleaf belongs to the Boston & Montana Co., an Amalgamated subsidiary, and according to the superintendent the vein strikes northwest and southeast, which will carry it through a corner of the Butte Exploration ground and directly through the centre of the

ground of the Butte & London. This company is sinking a deep shaft on the Greendale claim, situated a little west and north of the Greenleaf. Specimens of the rich ore have been on exhibition in different brokers' offices in Butte. George T. McGee, who had been in charge of the operations of the Butte Exploration, says there has never been any doubt in his mind that the company would have found commercial ore if it had sunk the shaft a few hundred feet deeper. The Greenleaf shaft will be sunk to a depth of 1,500 ft. before any exploratory work is done, and the Butte & London, which is now 1,025 ft. deep, will be taken to the same depth before cross-cutting is commenced.

The deepest mining shaft in the Butte district is that of the High Ore mine of the Anaconda Co., which is about 2,850 ft. deep. It will be sunk 75 ft. further and then work will be stopped and a station cut at the 2,850, from which point the levels will be run. The deepest mining is being done on the 2,400-ft. level of the Anaconda mine. The shaft of that mine is below the 2,500 ft. point. The company is also sinking on the St. Lawrence and doing development work in the Never Sweat. The

Montana.

J. I. C. and Gallatin shafts of the Anaconda Co., situated near the East Butte Co. mines, have been closed for a month on account of a strike of teamsters, the Gallatin and J. I. C. not being situated on a railroad. The two shafts had been yielding about 250 tons of ore per day. During the strike it developed that some of the local officials of big mining companies were interested in the ore-hauling business as an independent enterprise, controlling nearly all of the big teaming outfits, and in order to whip the strikers into line the Washoe and Clark smelters refused to receive any ore hauled by teamsters that had been granted an increase of wages by the small lessees and operators until the strikers should make a settlement with the big teaming outfits. The result was that a large number of lessees had to suspend work in all parts of the district.

Several Utah capitalists were in Butte last week to figure on building a smelter. They interviewed the officials of a number of the small mining companies and got estimates of the ore that could be furnished, and afterward opened negotiations with the officials of the Pittsburgh & Montana Co. with a view to leasing or purchasing the smelter building erected for the Baggageley experiments. It was said that if the parties could get that plant they would equip it with modern machinery

and methods. It seems to be the impression among persons familiar with the affairs of the Pittsburgh & Montana that it is not probable that the building can be secured by outside persons. The need of a new smelter in Butte is becoming so urgent that it is a question of only a short time until one will have to be provided to handle the ore produced by the new mining companies, the present works being entirely inadequate to handle even the present output of the district.

Denver, Colorado.

Freight Rates From Cripple Creek.—The Drainage Adit.—Progress in Various Districts.—Telluride, Silverton, Breckenridge, and Idaho Springs.

The shipping of the low-grade ores of Cripple Creek to the mills at Colorado City and vicinity, has received a decided stimulus from the new freight tariff of 75 cents per ton on ore running \$8 per ton and under. This is a reduction of 25% from the former charges. At the same time the rate on ore above \$40 per ton has been increased. This is of little moment, as it is understood that the mills and the smelters have a working agreement, under the terms of which the mills are not to contract for ore valued above \$40 per ton. At the same time a switching charge of 20c. per ton has been put into effect on all the ore that is handled by the samplers. This has aroused the wrath of the sampling companies, and the Taylor & Brunton Co. has secured an injunction to prevent the collection of the charge until its legality can be tested.

The driving of the deep drainage adit at Cripple Creek has received a decided check. The contractors had engaged to drive it at the rate of 300 ft. per month. After driving for five days, in which time they only advanced eighteen feet, they threw up the contract. The tunnel company immediately resumed work, and will carry it forward until another contract is made. The intention now is to sink a shaft about midway and advance the heading in each direction from this, as well as advancing the main heading. The failure of the contractors to live up to their agreement, which is ascribed to inexperience, is unfortunate, for it will make it difficult to obtain satisfactory tenders for completing the adit.

From throughout the State come reports of satisfying progress. At Telluride, the raise from the Stillwell tunnel has broken through into the upper workings of the Liberty Bell. With this event will come a change in the method of operating the mine. The ore broken in the upper workings will be let down by a counter-balanced skip to the tunnel level, and trammed to the entrance. At Rico, the motive power in the Group concentrator has been changed from steam to electricity, and the mill will soon be started. At Silverton, the tramway of the Detroit and Colorado mine is being pushed with all speed, and is expected to be completed by the middle of July. Meanwhile, the company is shipping about five cars of ore per week to the Ross smelter at Silverton. At Breckenridge, everyone is elated over the possibility of the Colorado & Southern building a branch road up the Snake river and another up French gulch. The Colorado Gold Dredging Co. has been exploring the Swan valley with churn-drills, and is about to begin the construction of two dredges. At Ouray the Mineral Farm mill will start up on the first of July. In the Daniel Bonanza a large body of rich lead ore is reported. At Lake City, the old Isalde group, which has produced some rich ore in the past, has been bonded to Silverton people, who hope to make it a productive mine once more. At Idaho Springs, a large orebody has been cut in sinking a winze in the Cardigan mine. The Stanley group of mines is also to be improved and

developed. The Scotia company at Silver Plume has driven through the dike on their property, and has been rewarded by finding an excellent orebody on the other side. At Central City, the heavy flow of water has caused several small properties to close down and at the Old Town mine an additional steam pump is being installed, as the electric pump is barely holding its own.

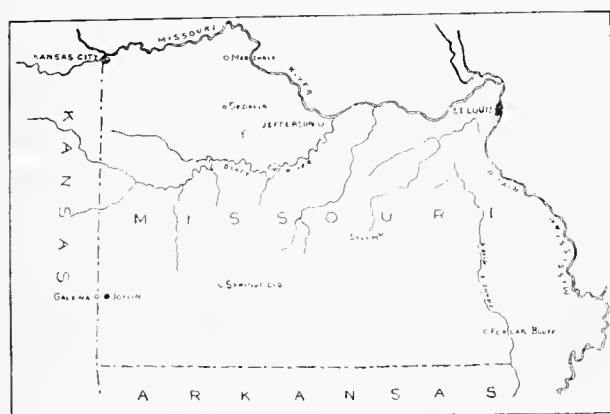

Mexico.

Chihuahua as a Smelting Centre.—New Plants and Old Mines.—The Mexican Mines Syndicate.—Activity at Concheño.

The conditions for the making of Chihuahua one of the most important mining, and possibly smelting, centres of the Republic are constantly improving. At almost the outskirts of the town is the famous old camp of Santa Eulalia, from which now the daily production is over 500 tons, being principally from the Chihuahua Mining Co., the Santa Eulalia Exploration Co., both shipping to the American Smelting & Refining Co. at El Paso, the Santo Domingo and Mina Vieja, leased to the A. S. & R. Co., and the San Toy Mining Co., of Charles M. Schwab and associates, which has just contracted for its product with the Torreon Metallurgical Co. At Minillas the Mexican Mines Syndicate, controlled by Donald R. Morgan and associates, of Monterrey, is opening up a number of old and almost abandoned properties, and is making an excellent showing by reason of having adopted up-to-date methods. This company has put a 100-ton concentrating plant on the Cobrizas property, which it is working under lease. By having an organized transportation service, and by using its own wagons, animals, etc., the syndicate is assured of the prompt movement of its own ores, besides making a nice profit on the carriage of all kinds of goods for others, and of its own supplies on the return haul. West from Chihuahua there is the wonderfully mineralized territory that is being opened up by the Chihuahua & Pacific Railroad to Miñaca, and beyond Miñaca by the Kansas City, Mexico & Orient Railroad. One of the richest mines in this part is the property of the Dolores Mines Co., near San Isidro station, in the Guerrero district, which has contracted for the high-grade ore with the A. S. & R. Co., but is largely independent by reason of its mill, from which the last shipment of bullion, just received in Chihuahua, and consisting of 56 bars, is valued at something over 100,000 pesos, and the property is supposed to be cleaning up about 30,000 pesos per month profit. But undoubtedly at present the centre of operations in that western region is the camp of the Greene Gold-Silver Co. at Concheño, a district which is variously spoken of, however, as the Jesus Maria, Ocampo, or Pinos Altos. In the latter part of last year the Greene Gold-Silver Co. bought the mines and mill of the Concheño Mining Co. for \$1,500,000, together with a large stock of supplies, which brought the amount paid up very close to \$1,600,000; and since that purchase the company has completed its Sierra Madre & Pacific Railroad from Madera to Temosachic, and a fine wagon-road from Temosachic to Concheño (with the intention of continuing on to Mulatos in Sonora), besides having acquired additional property, the most important of which is the Navidad. Close to 800 men are now in the company's employ; daily trains run from Madera to Temosachic, and from there daily stages (pulled by the company's animals), to Concheño, making the 85 miles in 18 hours. The company's offices have been moved to Concheño. The Greene people have also organized the Sierra Madre Land & Lumber Co. to develop the immense timber tracts purchased in the Sierra Madre, and they have also acquired the El Paso, Sierra Madre & Pacific Railroad,

which it is intended to continue from its present terminus to Concheño or the Jesus Maria district, and so obtain direct connection with El Paso. And at Ocampo the Watterson Gold Mining Co. is installing a 100-ton cyanide plant. And at Santa Barbara, west from Miñaca, the Silver River (Rio de Plata) Mining Co., under the management of D. W. Shanks, has had its amalgamation mill running for a month on a remarkable body of ore averaging close to 100 oz. silver per ton.

The Nuevo Rosario Mining Co. has been organized as a holding concern for the Rosario Mining Co. for the purpose of operating the Condesa, Zuloaga, Rosario, and Providencia mines, in the Bolanos district, of Jalisco. Dr. J. H. Spence has been appointed general manager and has taken active charge. These mines are known as *antiguas*, and the old records show that at one time in their history they were great producers of rich ore. The workings are extensive. The first work of the new company will be to start an adit on the Zuloaga. It will be 2,000 ft. long and is expected to cut the vein at a depth of

Sketch Map Showing Position of Joplin.

1,100 ft., which is well below the old workings. The company is composed of Americans, headed by George J. Atkins of Lancaster, Pa. Among the improvements planned is a new concentrating plant.

The Santa Barbara silver mine, situated at Guzapares, in Chihuahua, has been placed upon a paying basis by the erection of a new mill by the Compania Minera de Rio de Plata, which owns it. The manager is Clarence C. Chase.—The new 120-ton mill of the Peregrina mining Co. at Guanajuato is now in successful operation.—It is reported that an English syndicate will erect a smelter on the Hacienda de Adjuntas, situated near Monclova, in Coahuila. There are several rich mines in that district from which the proposed smelter could draw a supply of ore. El Panuco mine, which is controlled by Otto Wahrmond, of San Antonio, Texas, contains high-grade copper ore. Mr. Wahrmond and associates recently finished building a railroad 40 miles long from the mine to Monclova, where it connects with the Mexican International.—El Rayo Mines Co. is said to have acquired the properties of the Buena Vista Consolidated Gold Mining Co. in the Santa Barbara district of Chihuahua. This company has also taken over the properties of the El Rayo Mining & Development Company.

The 800-ton lead and copper smelter of the American Smelting & Refining Co., now being erected at Chihuahua, is nearing completion. It will be blown in next November. It is stated by Willard S. Morse, an official of this company, that it has about 70,000 tons of its own ores and more than 30,000 tons of fuel tied up along the line of the Mexican Central on account of the car shortage. He says that a number of mines have had to shut down because of lack of cars. Very few of the smelters in Mexico are working to their full capacity.

Joplin, Missouri.

Big Production.—Slackening Market.—Record of Shipments.—The Mining Congress.—News from the Mines.—Several Strikes.

The highest price reported paid for zinc ore last week was \$51 per ton on an assay basis of \$46 to \$48 per ton of 60% zinc. These prices have ruled all during this month and there is no indication of a change at present. Lead ore has taken a big slump since the first of the month, dropping from \$83 to \$78 per ton in the week of June 8, then to \$76, and last week to \$74 as the high price. There is a light demand and the sales are far below the average for the previous months of this year. As regards production, the district was never in better shape, the zinc output being about 6,300 tons and the lead production nearly 1,000 tons per week.

Shipments.	l.b.	l.b.	\$
Week of June 22.....	12,537,330	1,315,560	330,288
25 weeks this year.....	303,228,280	46,902,600	8,986,886
25 weeks last year.....	281,504,390	36,513,150	7,019,742
Increase.....	41,723,890	10,386,450	1,967,144

The publicity committee for the coming Mining Congress, the official call to which has just been issued, has commenced work by establishing a bureau with Jesse A. Zook in charge. An active campaign of advertising will be undertaken by the bureau and kept up all summer, increasing in volume as the date approaches. It is the purpose of the committee to give the most complete and comprehensive publicity to this convention. The new \$600,000 Connor hotel will be completed and opened the first of November, and with the other local hotels will be in position to accommodate all the delegates and their friends.

The Federated Mines & Milling Co., one of the largest operating companies in the entire district, with mines at Joplin, Webb City, Alba, Neck City, and Badger, has just purchased a 40 acre fee adjoining Allen Hardy's Big Indian mine at Neck City. Before buying this land 14 drill-holes were put down and ore encountered in all but two of them. The faces of ore varied from 12 to 35 ft. at depths between 185 and 220 ft. The property gives evidence of being a splendid one, and developments will be pushed vigorously.—A 16-ft. face of zinc ore was encountered in a drill-hole by the Uneeda Mining Co., operating in the Porto Rico sub-district, at a depth of 185 feet.

Southeast of Granby, at Newtonia, a development company is drilling the Duval and Wyatt lands, and the results are promising. On both lands ore has been found above the 200-ft. level but the drills will continue to the 300-ft. level, in the hope of finding the deep run of mineral that is thought to exist in that vicinity. The strike of zinc ore, made by Scott & Coleman on the C. W. Tooker land at Aurora, is considered to be one of the richest and biggest finds ever made in that locality. There is a face of over 80 ft. of rich zinc, and it was made on land never before prospected. The recent strike on the McLain land looks good, but it will take some development to prove its worth. Aurora is just at present in splendid shape and the turn-ins are growing rapidly.

The new owners of the Politicians mine are highly pleased with their property, which they purchased last week for \$65,000. It consists of a 20-acre lease and a new mill, which had just been completed at a cost of \$15,000, and had only been operated one day when the deal was made. The property is located in the Zincite sub-district, northwest of Joplin, and several other new strikes have been made there recently.—Sparks, Moore & Henderson, of Galena, have made a rich strike of mineral in a drill-hole on the Murphy land at Galena at a depth of 75 ft. and have penetrated 65 ft. of ore. Work of sinking a shaft will begin at once.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE rim of a pulley intended to carry a flat belt is generally slightly rounded, in order that the belt may remain in the centre of the pulley-face, instead of working to one side, as is the case with flat-faced pulleys. The amount of this rounding may be taken equal to one-twentieth the width of the belt.

SINCE the circumferential velocities of any two pulleys, which are connected by one and the same belt, are the same without regard to the diameter of the pulleys, and since the circumferences of the two pulleys are directly proportional to their diameters, the ratio of the numbers of revolutions of the two pulleys is equal to the inverse ratio of their circumferences, diameters, or radii.

BELTS are commonly made of leather, cut into strips of the required width, and riveted together at their ends to make up the required length. Strips taken from the back part of the hide, and oak or hemlock tanned, are generally considered the best, although some kinds of patent-tanned leather are said to have great adhesive power. Cow's hide is almost invariably used for the leather of belts.

OWING to differences in form, texture, color, etc., gypsum presents several varieties, some of which have been given distinct names. The ordinary form in which gypsum occurs in the workable deposits is as massive or rock gypsum. Alabaster is a pure white, fine-grained, massive gypsum, occasionally used for statuary, etc. The term selenite is applied to the crystalline, white, almost transparent gypsum.

SALT occurs in lagoons along the Gulf coast and in many salt lakes, or 'salines,' throughout Texas, from which much is taken annually. No report of this production reaches the United States Geological Survey. The region of present commercial importance is in Van Zandt and Anderson counties, where salt is made from artificial brines drawn from wells which enter heavy beds of rock salt in Cretaceous strata at several horizons.

IN the search for and the mining of tourmaline, beryl, topaz, kunzite, and other stones peculiar to the southern counties of California, some wonderful crystals of rose-colored beryl implanted on feldspar and many fine crystals of tourmaline (red and green) are found, and in connection with these occur many specimens of great interest to the science of mineralogy. The region bids fair to excel that of the Ural Mtn., which for more than half a century has led the world in such products.

THE bituminous sandstones of California are well developed in the vicinity of Santa Cruz. They are, in fact, beach or marine sands heavily impregnated and loosely cemented together by the asphaltic residue of a heavy oil similar to that which is raised from submerged beach sands at Summerland and elsewhere in California. The hard Ventura county asphalts show a more advanced stage of the process which has gone on in the beds near Santa Cruz. The beds containing these hard and soft asphalts have been determined to be of Tertiary age.

TITANIUM is unique among the metals used for steel alloying purposes, as the raw material, that is, ore containing titanium, is most abundant, but the metal and its

alloys are distinctly rare, and while it is known that titanium imparts to the steel most valuable properties, its application is still in its infancy, because the technical difficulties in an economic production on a large scale have not been overcome as yet. The principal advantage of the presence of titanium in steel is that it increases the density of the material and particularly its transverse strength, thus giving a harder chill and better wearing quality.

THE ore deposits of the Kentucky-Illinois fluorspar district occur in veins along fissures produced by faulting of the sedimentary rocks. The principal mineral occurring in the veins is fluorspar, the remarkable abundance of which is the striking characteristic of the district. Calcite, quartz, and barite are likewise abundant. Kaolin is occasionally associated with these minerals. The original metallic minerals of the veins are galena, blende, pyrite and marcasite, chalcopryrite, and stibnite. Few secondary minerals have been reported. The principal are cerussite, smithsonite, limonite, malachite, and native copper.

IN deciding on the length to cut a belt to fit over two pulleys, the easiest way is to stretch a steel tape over the pulleys in the same position that the belt will have, thus getting the length directly; and if a rubber belt is used, allow one-quarter of an inch per foot for stretch. For instance, if in this way the measurement should show a length of 28 ft. required, cut it seven inches shorter than this, and it will fit. If it is not convenient to measure in this way, the length can be accurately computed by the use of a formula involving the distance between centres of the pulleys and the two radii; or a good solution may be had by graphical methods, the result being scaled from the drawing by a rule.

FOR the purpose of experiment, a number of tool steels have been made, the carbon percentage varying from 0.4 to 2.2%, and the method of hardening was to heat the steel to the highest possible temperature without destroying the cutting edge, and then to cool rapidly in a strong air-blast. By this simple method of hardening it was found that the greatest cutting efficiency is obtained where the carbon ranges from 0.4 to 0.9%, and such steels are comparatively tough. Higher percentages are not desirable, because great difficulty is experienced in forging the steels, and the tools are inferior. With increasing carbon contents steel is also very brittle, and has a tendency to break with unequal and intermittent cutting.

FOR all practical purposes there are two kinds of belting—leather and rubber—between which there is the following comparison: Those who favor leather belts claim that they are in the main stronger than rubber, and they will wear much longer, especially when used for cross or half-cross pulleys; that leather belts cease to stretch after once or twice shortened and re-laced, while those of rubber do not; and that leather will bear contact with oil and grease without harm, while rubber thus exposed will soften, and stretch out of shape. Wide leather belts can be cut up into narrow ones, while rubber belts cannot be cut without injuring the finished edges; also, leather can be more easily repaired when injured than rubber. On the other hand, rubber belts do not need to be riveted, but are made continuous; they do not slip as easily on the pulley-faces as leather, and are cheaper at first cost for the same sizes. It is also claimed that rubber belts endure exposure to cold and wet much better than leather, retain their flexibility better, and do not lose strength as rapidly from wear.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Dressing Plates in a Mill.

The Editor:

Sir.—Since my article on 'The Position of Plates in a Mill,' which you so kindly published in the MINING AND SCIENTIFIC PRESS a few months ago, I have had some further experience with ruined plates.

On my arrival at this mine, the manager informed me that his millman (who had just left) could not save more than about 20% of the free gold, that he had scrubbed and rubbed the plates for all he was worth, and had used about five pounds of cyanide of potassium on them in one week. Also that the ore contained some lead, which might hinder amalgamation. Just think of it; five pounds of cyanide in one week! Well, at least one-half of the plates were as red as a fox's tail.

Now, Mr. Editor, nearly every millman has his 'dope' to put on just such plates, and most of them speak of it as a great secret, and it never fails. I have my dope also, which never has failed me. I don't know as I have ever given it away before, but will do so now. I washed the plates as usual with clean water, rubbed in some mercury with a whitewash brush, and started up; and you can realize how astonished I was on cleaning up the plates next morning, to find that where the silver plating had not been destroyed, they looked fine and the amalgamation was as good as I ever saw. I then left a good plaster of soft amalgam on the plates every time after cleaning the plates, which soon began to cover the red portion of the plates like new skin growing over a fresh wound. Of course, I had to make good to keep from following the other millman, and well, that was over six months ago, and I am here yet.

That plaster of amalgam that I leave on the plates is my dope. I have tried all the others that I ever heard or read of, and came to the conclusion that where some of them appeared to succeed, it was in reality the plaster of amalgam that was the cause of it. Anyway, it has been my only dope for years, and it does not fail me.

H. P. GORDON.

Hailey, Idaho. June 16.

The Requirements of Modern Mining.

The Editor:

Sir—How can one discuss such an article as this of Mr. Finlay, when one is so thoroughly in accord with it? He has pointed out very clearly the immense field covered by the mining of today, and the utter impossibility of any one man, engineer or other, compassing the whole, even though he be a Napoleon in mining.

The subject is so comprehensive, and its ramifications so numerous and detailed, that the various branches became specialized and sub-specialized long ago, and the engineer who devotes himself to a single metal, as for instance copper, has a sphere ample in itself for all his energies, while men have found their life's work in such apparently subsidiary matters as the cyaniding of gold-bearing sand and slime.

Whence we may deduce the beatitude: Blessed is the engineer who recognizes his own limitations; who does not attempt to decide the details of an ore-treatment, or determine the dimensions of a steam cylinder, or the type of motor for a given piece of work, when he knows there are specialists who can do it more efficiently. For the crux of the whole subject is business results, and modern

mining requires that the balance shall be on the right side of the ledger at the close of the year.

The engineer cannot afford to lose sight of this main object for a single moment, but surely no one would include in the sphere of the engineer or the 'mining man' the marketing of the product. This is again a specialty, and whether the product be copper ingots or 'cuff buttons', its sale is usually entrusted to a man skilled in that particular branch of business.

In short, mining is today a huge departmental business, quite as much so as any of the great emporiums in our large cities, and, if properly conducted, a specialist will be found at the head of each department of mining, milling, smelting, or what not, while in even smaller operations the same system applies, and the manager has, or should have, his staff of surveyor, chemist, electrician, chief mechanic, etc., to attend to the work of each department. The controlling head of all the departments certainly need not necessarily be, and oftentimes is not, a mining engineer, but I believe the chances of continued success are greater if he has had the preliminary training of the mining engineer.

Mine valuation may depend upon just such a change of working conditions (hardly to be termed a "trick of operating" however) as cited by Mr. Finlay; and so may the valuation of a cuff-button factory; and the man who examines the latter and finds that he can by raising the manufacturing costs 10%, raise the grade of the buttons 25% and increase the profits 100% over the existing conditions, will be able to make a successful cuff-button industry and increase its valuation just that much. All of which brings us back to the personal equation, which is just as potent in mining as in anything else.

It generally takes time to discover these possibilities in the working conditions surrounding a mine (or a factory), which is probably the reason why it was not done earlier in the instance referred to, and the valuation made while the original conditions obtained cannot be condemned as inaccurate. It was as correct as the premises upon which it was based, which were also correct at that time. It is these changes of conditions that constantly alter all valuations not only in mining but in all fields of industry, though the difficulty the mining engineer has often to contend with is that after having made a valuation, he is held responsible for any subsequent alteration in value due to changes that are entirely out of his, and often anyone's control. Many base metal mines that were unworkable at a profit three years ago pay handsomely today.

Mine valuation certainly covers much more than the mere sampling and measurement of the ore-reserves, as Mr. Finlay points out. In the determination of the further problems, experience and matured judgment count here as elsewhere. But, surely, it is within the province of the engineer to determine the financial features, by which I mean the capital upon which the property can pay interest, and the proper amount of working capital required to reach the producing stage. It is quite true that these features are oftentimes not left to the engineer to determine, but that he should be competent to deal with them is in my opinion self-evident, as the determination of the amount of profit available from a given ore deposit is the chief object of the examination and upon this base the financial superstructure must rest.

Many perplexing questions often arise in this connection, due to the inevitable overlapping of the technical and financial departments of the mining business. Engineers have been censured by some for daring to step out of their prescribed province of ore-reserves and profit in sight, and condemn a mine because of its over-capitalization, but nevertheless this is oftentimes not only a legiti-

mate but a necessary thing to do. If the instructions definitely limit the work and opinion to the amount of ore and the net profit in sight, the engineer's skirts are clear of further responsibility. But if, as is so often the case, he is requested to take a comprehensive view of the whole proposition, he is forced to look at the financial side as well as the technical. For instance, if one is aware that certain debentures or other debts exist on a property under examination, shall the engineer with only general instructions to examine and report, omit to set off this debt against the amount of profit he finds in sight.

To my mind it is clearly his duty not to omit the debt as the report read by one unacquainted with the financial condition of the company, gives otherwise a false idea of the position.

These are perhaps ethical questions, but they are very practical ones, and they tend to show forcibly how the different departments of mining overlap, though one could of course cite instances in the geological, metallurgical, or other branches of the industry that would demonstrate this equally well. In short, the interdependence of the various departments of mining makes *co-operation* the chief requirement of modern mining today. The geologist, the metallurgist, the chemist, the engineer, the financier, all must co-operate in solving the problems connected with a single ore deposit and its successful exploitation, and when this co-operation is properly applied the results are assured.

That the ultimate head of the entire business is so often the financier is only natural. It is the case in most industries.

THOS. H. LEGGETT.

London, May 24.

The Rejected British Workers.

The Editor:

Sir—Those acquainted with the practical and economic conditions that obtain on the Rand at the present time, will not be surprised at the cabled news that the mine-owners wish to give the Afrikanders a trial to become rock-drill men, in place of the British and foreign miners that have evidently come to consider it as their special right and privilege to make money out of the Rand gold-mining industry.

Doubtless many will think that they see in this movement some further wickedness on the part of the capitalist, or of 'sliminess' on the part of the Boer Ministry, according to their political views. Others, better informed and less prejudiced, will see in this experiment that the mine-owners wisely intend to leave politics alone and are willing to join hands with the Boer Premier in all efforts that he may make to foster the one industry upon the success of which all others must depend.

The Afrikander has, generally, a good knowledge of the various Kaffir languages and consequently knows how to get the most out of Kaffir labor, an art in which the British or foreign miner frequently fails. There are many who, I think very rightly, contend that there are probably sufficient Kaffirs in South Africa to supply the mining industry even without the aid of the Chinese coolie, if only worked at anything like fair efficiency for wages received. The British and foreign miners have been spoiled by too much assistance from so-called cheap unskilled labor, and mine-managers have often themselves been guilty of permitting the miners to use Kaffir labor extravagantly, so that, as a matter of fact, Kaffir labor was the reverse of cheap.

The Boer Ministry, being well acquainted with this side of the question and having undertaken gradually to replace the Chinese coolies with Kaffirs or other natives,

is well aware also of the limited supply of Kaffirs at all fit for mining work. It is now suggested to mine-owners that an earnest attempt should be made to give employment to a class of men who know how to live economically in the country, are content to permanently reside in it, and will (unlike all the rest, whether Kaffir or British) spend their earnings within the Transvaal, instead of in Portuguese territory, China, or Europe. All mining communities recognize the inestimable advantage of a permanently resident set of miners, who live with their families and whose children take their places. Surely, if for economic reasons, the British or foreign miner refuses to accept the pay that the Afrikander is well content to take, it is merely a question of the survival of the fittest, and no blame can be attached to the mine-owner. On his side, the mine-owner, tired of quarrels and of being bullied by labor-unions, turns with relief toward a class of men like the Afrikanders, who as yet know nothing of unions and strikes and other labor combinations, are not clannish like the Cornishmen, and after a few short months of trial work should be quite as able to learn how to work the machine-drills as Kaffirs and coolies. All that would then be needed, is the intelligent minerlike superintendence by the employment of a comparatively limited number of highly experienced and well-paid miners, engaged to make the rounds of the working places, and see that the drill-man, whether he be Afrikander, Kaffir, or coolie, was breaking down his rock to the best advantage, pointing holes in the right directions, and finally charging and blasting them. Shareholders in the Rand mines will rightly hail with delight all these most sensible movements toward effecting greater economies in working. It is silly for home politicians and others to now cry out that in this experiment to give the Afrikanders a chance to become miners, the Boer Ministry wishes to oust the British from the country, or that the mine-owner (rightly disgusted with the Chinese 'slavery' talk), is going to have his revenge on the Government by also appealing, through false arguments of Boer employment against Britain, to the universally ill-treated taxpayer of war debts.

It is all quite natural, simple, and business-like when looked at through any other spectacles but those worn by the prejudiced politician, or even by those others who always under all circumstances are suspiciously looking for "the nigger in the fence."

EDGAR P. RATHBONE.

London, June 14.

MINING IN SWEDEN.—From the latest official reports there were 326 iron mines worked in Sweden in 1905. The total production was 4,464,833 tons of ore. This is a decrease of 40 mines, but an increase in the output of 380,888 tons, compared with the previous years. The total value of the ore products was \$6,164,781, against \$5,700,005 in 1904. During 1905 there were in operation 129 furnaces, producing 539,437 tons of pig iron, worth \$10,091,896. There were also 511 other iron and steel concerns producing ingots, etc. The value of the unwelded iron blooms was \$5,379,702, of ingots \$9,835,651, and of blistered steel \$17,159. The value of the charcoal used in the whole iron-producing industry was \$5,858,852.

—There were also produced in Sweden, gold ore valued at \$36,450; silver and lead, \$52,801; copper, \$114,255; manganese, \$7,961; zinc, \$796,666; sulphur pyrites, \$59,019; coal, \$636,550, and clays, \$106,313. The number of persons employed in the manufacture of the different metals was 3,222. During the year, 1,107 accidents occurred, resulting in 30 deaths. There were 91 strikes, involving 113 establishments and 8,950 laborers.

Suggestions for Field Observations of Ore Deposits.

By S. F. EMMONS.

*The first task of a geologist in examining a mining district is to obtain as clear and accurate an idea as possible of its structure and geological history. If it is impracticable to make an exhaustive study, he should at least endeavor to trace the important dynamic events that have brought about the existing structure. It may be assumed that, with rare exceptions, ore deposits are the result of concentrations, often many times repeated, by waters circulating within the rocks, of materials previously disseminated in a less concentrated form elsewhere. Such circulating waters always tend toward channels which admit of more ready circulation, what Van Hise calls 'trunk channels,'† and these channels have in most cases been produced by dynamic stresses; it is evident that their study presupposes a knowledge of the orographic history of the region.

Furthermore, as a general rule, the various processes attendant upon ore deposition tend to obliterate structural and textural features of the rocks and often one can only study these features satisfactorily at some little distance from the actual ore deposits.

The phenomena to be observed fall naturally into three classes, though their observation may be simultaneous: (1) Mechanical; (2) mineralogical and chemical; (3) economic or commercial conditions.

The first have to do with the water-channels, hence with the form and probable extent of the orebodies. The second, with their mineralogical composition and the nature of the chemical processes which resulted in their deposition; the third, with the extraction of the ores and their subsequent reduction to the metallic condition.

MECHANICAL PHENOMENA.

1. *Vein-fissure Fracturing.*—The most evident result of mechanical stresses on rock-masses is the formation of fractures or fissures, which when mineralized may form veins. These fissures are in general, strictly speaking, fault-fissures, though the displacement is often so slight as to be imperceptible. On the other hand, large structural faults are not often found to be mineralized sufficiently to form orebodies. Some writers on ore deposits speak of vein-fissures as sometimes resulting from contraction, but I have yet to learn of a well authenticated instance. I regard a certain amount of movement as necessary to break the cohesion between the respective walls of a joint or fissure sufficiently to make a water-channel. This I hold to be true also of eruptive contacts. Observations bearing on these points are useful. It is to be noted that a contraction-fissure could not extend from one rock into another.

2. *Direction of Fissure-planes.*—The direction of fissure-planes, both in dip and strike, and their relation to the general joint or fissure-systems of the region should be determined; but it should be borne in mind that in nature fissures are not mathematical planes but more or less warped surfaces. The average direction of a given system must be determined from as large a number of observations as possible; a few, however accurately determined, will not necessarily give the true direction.

3. *Periods of Fissuring.*—Find out whether there has been more than one period of fissuring; whether one set of veins crosses and throws another. Here caution is necessary, for there may be an apparent throw produced

by contemporaneous fracturing‡. A vein may end against another and be apparently continued on the other side at a given offset, but if the latter has faulted the former there should be internal evidence of movement in the vein material, and other veins of the same system should be faulted in like manner and amount. The burden of proof is on the faulting. If the evidence is conclusive, the second period of faulting should be correlated with some known dynamic movement of the region.

4. *Post-mineral or Secondary Fissures.*—It is important to look for evidence of recent or post-mineral faulting that may be connected with secondary enrichment of the deposits; where, as is often the case, this is parallel, or nearly so, to the plane of the vein, it is sometimes difficult to detect. It may show merely as a clay selvage; it may be a distinct breccia zone carrying fragments of ore, quartz, and country rock. The criteria are ground-up fragments of ore, and moisture that evidently comes from the surface; unless one of these is present one can not be sure of its secondary nature. If the country rock is feldspathic, there is often kaolin-mud in the secondary fracture.

5. *Character of Fissure.*—In regard to the character of the fissure; it may be a single strong fissure, or a combination of parallel fractures, which may be sufficiently numerous to constitute a shear-zone. In the case of the single fissure the vein material is more likely to be the filling of an open space and to be enclosed within well defined walls. Even in this case, however, there are likely to be fragments or sheets of country rock that fill a considerable portion of the space between the walls, and one must observe closely whether the vein material is not in part the replacement by quartz or metallic minerals of some of this dragged-in material. Cross-cuts in either wall should also be observed to see whether the supposed wall is actually the lateral limit of mineralization, or if there are not mineral-bearing fissures behind it.

6. *Fissure Zones.*—In the fissured zones the ore is more likely to be a replacement of the country-rock by mineral solutions eating outward from the crack or fissure, in which case the walls which define the lateral limits may be wanting. When the ore follows for a certain distance one fissure, then passes by a cross-fissure to another nearly parallel, but set off a little to one side, and so on, it constitutes a 'linked vein.'

7. *Influence of Country-rock.*—The country-rock has some influence on the character of the vein-fissures. Where it is a homogeneous mass the vein systems are likely to be regular; but in passing from one rock to another the character of a given fissure may change. The character of such changes should be noted. In passing from a rigid rock to a plastic one a wide vein may pinch to a mere crack.

8. *Indistinct Fissures and Mineralized Dikes.*—There may be nothing that one could strictly call a vein along the zone of fracture; simply a shattering of the rock and an impregnation or replacement by silica or vein minerals. This is likely to occur in siliceous rocks. Not infrequently there has been a first intrusion of igneous rock in dike form along such a fracture and subsequent movement within the dike which is usually so decomposed in the vicinity of the orebody as to be little more than a mass of clay. Such occurrences require following out along the strike to some less altered region and the detailed study of intersections for a determination of actual relations.

9. *Ore Chimneys.*—What the miner calls a 'chimney'

*This valuable contribution was received from its author with the following note: "I beg to submit the following suggestions for field observations in economic geology which I have been in the habit of making to geologists of the Survey, thinking they may be of use to some of your readers."—Editor.

†Some principles controlling the deposition of ores, *Trans. A. I. M. E.* Vol. XXX, 1900.

‡Daubrée's experiments on tensional strains, *Géologie Expérimentale*, p. 310.

of ore'—a body of a rudely circular cross-section—is apt to be difficult to characterize. Sometimes it is a fairly solid mass of metallic minerals; sometimes they simply form the cement for breccia fragments of country-rock, in either case largely by replacement. I have generally been able to account for such bodies as zones of more or less shattered rocks at the intersection of two or more fracture-planes. Such planes may be difficult to recognize in the immediate vicinity of the ore, being obliterated by the action of mineralization, but they can generally be found in the neighborhood.

10. *Ore bodies in Limestone.*—Because of their solubility the channels that admitted the solutions to rocks like limestone are often difficult to trace; the ore is more likely to be a replacement than a cavity-filling. Cases do occur where it is the filling of well defined fissures, and occasionally of open caves. In such the bands of successive deposition or 'crustification' should be recognizable. Existing caves can often be proved to be of later formation than the ore. Bounding bodies of more or less pervious rock will have an important influence upon the circulation of solutions and this influence should be studied. When the solutions have passed along a given fracture or joint-plane and then crossed to another their track may be difficult to follow. In one place a large chamber of ore may have been formed, and this may be connected with another by a crack so small as to be scarcely visible. It is in the unreplaced or barren portions of the rock that one can best detect the fracture-systems. In bodies of replacement in limestone the ore generally grades quite slowly into unreplaced rock with no defined boundaries. In the midst of a large body of unoxidized ore one can generally trace, along the walls of the drifts that have been opened long enough to allow the dust to accumulate on the walls so as to deaden the metallic luster, the bedding and joint-planes of the original limestone, and sometimes, in the roof, the crack through which the mineralizing solutions entered.

11. *Ore in Limestone Near Intrusive Bodies.*—Where large bodies of igneous rock have been intruded through or across limestone beds and mineralization has ensued, caught-up fragments of limestone wholly or partly enclosed in the igneous rock are often so completely replaced by ore that no limestone can be found. One may detect, however, some relics of the rock structure or some of the lime-silicate minerals into which the limestone has been transformed. Where there has been faulting near the contact of limestones and igneous rocks, mineralization often takes place in the fault material; interstices are filled and limestone fragments replaced.

12. *True Contact Deposits.*—Finally, there are ore deposits in limestone in the vicinity of large masses of crystalline eruptives where no related fracturing or joint systems can be traced. Ore minerals are associated with contact minerals, such as amphiboles, garnets, vesuvianite, etc., and magnetite or specularite are mixed with pyritous minerals; the orebodies are extremely irregular in form and have no definite boundaries; they are often crossed by dikes of eruptive rock that are neither mineralized themselves, nor have appreciably disturbed the orebodies. To these has been ascribed a probable pneumatolitic origin and the name 'contact deposits' proposed. When such are observed they should be studied with special care.

13. *Observations in Mines.*—If one has occasion to examine a mine with extended workings, one should first study the map of these workings and endeavor to form some idea of the underground structure from such trustworthy information as may be given. One should

take into the mine with him a copy of the drifts he has to examine, or a rough reduction thereof made in his note-book. In his journeys through the mine, let him keep mental account of the structure and of the bearing upon it of the phenomena observed. If they do not fit the hypothesis adopted, let him stop from time to time and reason out what other conception they better fit. Before leaving the place, let him construct cross-sections to graphically test his hypothesis. If he has not accurately measured data, let him get the best approximations available. Thus, he will often be able to decide where the critical points lie and to settle the question by a final visit; whereas, if it were left until he returns to the office, it might necessitate waiting until another season before the decision between the two alternative hypotheses could be arrived at.

CHEMICAL AND MINERALOGICAL PHENOMENA.

It is assumed that the geologist is familiar with the more common ore minerals and with their appearance in ores, which often differs considerably from what is ordinarily seen in mineral collections.

14. *Zones of Oxides and Sulphides.*—In examining a mine he will note the zone that separates the original deposit, the sulphides, arsenides, antimonides, and tellurides, from the oxides, carbonates, and sulphates, which have resulted from their alteration by atmospheric waters; he will see whether there has been any enrichment or impoverishment of the ore above or below this line, any segregation of the metals by migration, and endeavor to trace the causes thereof. It sometimes happens that a mineral occurs in the oxidized zone whose corresponding original is not found in the lower zone. For instance, oxide of manganese, whose original form would be the carbonate or silicate, rhodochrosite or rhodonite.

15. *Iron Deposits.*—In iron deposits one should endeavor to determine whether they result from the oxidation of sulphides or were originally deposited as oxides. In the latter case if they occur in igneous rocks, let him look for evidence that they were formed by magmatic differentiation, and if such evidence is found, let him also search for evidence of subsequent concentration by aqueous agencies. If in sedimentary rocks, let him see if they have been formed by a concentration of disseminated material by surface or other waters, or are simply residual deposits.

16. *Copper Deposits.*—In copper deposits it may be assumed as a general rule that the original form of the deposit was chalcopyrite associated with more or less iron pyrite; generally more. Enargite is also an important source of copper which so far as known at present is an original mineral. Evidence bearing upon this point is valuable.

17. *Silver Deposits.*—In silver deposits this metal is generally associated originally with iron, lead, and zinc sulphides; also with copper sulphides and sulpharsenides. The less valuable minerals are likely to much exceed in bulk the silver minerals, the latter very frequently being indistinguishable except under the microscope. If there are large bodies of very rich silver ore not far below the zone of oxidation there is reason to suspect secondary enrichment and to look for evidence of it.

18. *Gold Deposits.*—In gold deposits it is important to ascertain whether the gold was originally in the form of telluride, for in this case the cost of reduction is likely to be much increased. This is difficult unless the ore is exceptionally rich so that the tellurides are visible to the naked eye. Make note of any trustworthy analyses and bring in material for chemical and microscopical tests.

19. *Secondary Enrichment.*—It is important to look

for evidence of secondary enrichment, as this may afford criteria for judging of the probabilities of the continuance of pay-ore in depth. It is based on the broad general fact that the sulphates formed by the oxidation of sulphides near the surface are leached down, even into the unaltered portion of the deposit, and in the presence of relatively large masses of iron sulphides will be reduced and re-deposited as sulphides. In this process segregation of the metals may take place according to the differing solubility of their sulphates and their affinities for sulphur.* Climatic conditions and the amount of erosion that the region has been subjected to have a bearing upon the process. The favoring structural conditions have already been mentioned. Some of the mineralogical indications follow:

20. *Copper Deposits.*—In copper deposits, the richer sulphides, chalcocite, bornite, and covellite have been found in most cases to be secondary enrichments of chalcopyrite. The amorphous black ore often occurring near the line between oxides and sulphides, sometimes called 'sooty' ore, is definitely the result of leaching down and re-precipitation. It has hitherto generally been called 'black oxide' or 'oxysulphide,' but chemical examinations of specimens tested thus far have proved them to be an impure chalcocite. If found in such quantity that it can be obtained free from impurities it should be saved for chemical tests. Large bodies of iron oxide that result from the oxidation of iron sulphide may be expected, if they contain a trace of copper, to pass downward into pyritous ores, enriched by copper sulphide, and then into normal pyrite with a little copper sulphide.

21. *Silver Deposits.*—In silver-bearing ores the very rich silver minerals, such as horn silver and the native metal, occur in the oxidized zone. The rich sulphides, arsenides, and antimonides, with the mixed minerals polybasite, tetrahedrite, etc., in the sulphide zone are liable to be of secondary origin. This can be proved when they are the last deposit in vugs and cavities and are connected with water channels leading to the surface. Native silver may also occur in the sulphide zone as the result of secondary alteration.

22. *Base-metal Deposits.*—In the baser ores, where, as is not infrequently the case, there is a decided predominance of lead compounds in the upper portions and zinc and iron sulphides at lower levels, there is a suggestion of re-distribution since original deposition in virtue of the lesser solubility of the former. Gold, though readily insoluble, is attacked by ferric sulphate and precipitated when the latter assumes the ferrous condition. This, together with the fact that near the surface the soluble sulphates of the other metals are more readily removed by surface waters, will probably account for the common decrease in value of gold ores from the surface downward.

ECONOMIC AND COMMERCIAL CONDITIONS.

23. *Conditions of Persistence.*—The geologist is generally expected to give some opinion as to the future of a mine or mining district. He must summarize the evidence gathered. Favoring conditions for persistence are (a) evidence of strong dynamic action, which would produce strong fissure-zones and abundant water-channels; (b) abundant igneous intrusions, and evidence of strong chemical action in the alteration of the rocks, and (c) a visible impregnation of the rock-masses in general with metallic minerals, even if of no commercial value. The most important is the actually proved existence of large bodies of valuable ore. As a rule, large bodies of low-grade ore will lead to more permanent industry than very rich ores.

24. *Commercial Conditions.*—The general commercial conditions should be also considered; the proximity to and accessibility of the region to railroad lines, and consequent approximate cost of bringing in supplies and machinery and taking out ores; the question of supply of water for generating power, or for reduction purposes; of timber for building and mining work; of fuel for steam, and, if need be, for smelting, must be considered. Copper ores and most lead and zinc ores involve smelting operations, hence in their case cheap transportation is more indispensable; whereas, gold ores can frequently be reduced on the spot by amalgamation, cyanidation, or chlorination, and this may often be carried on at a profit in relatively inaccessible districts. It must be borne in mind, however, that telluride and pyritous gold ores generally require preliminary roasting.

25. *Historical Data.*—Data should be obtained on the spot as to the history of discovery and development of a mining region, paying especial attention to facts which bear upon what might be called its economic evolution. Also, all trustworthy data that may be of use in estimating the aggregate production of the various metals mined.

RUSSIAN IRON INDUSTRY.—Notwithstanding the depression in the Russian iron industry, the extraction of the southern hematite ores continues to increase. This is due to the rapid growth in the export of these ores to Silesia and Westphalia, which rose from 220,000 tons in 1905 to 460,000 tons in 1906, which was about 10% of the output. In view of the small available quantity of these ores, estimated at only 66,000,000 tons, this increase in the export is causing some anxiety to the local mill owners, as the other ores in the district are of poorer quality and less importance, the output having decreased from 180,000 tons in 1899 to 28,000 tons in 1906. The peninsula of Kertch, on the other hand, possesses valuable deposits of the metal, estimated at 466,000,000 tons, but owing to the backward condition of the industry in this region the yearly amount of ore smelted is not above 250,000 tons. The mines of the Ural, where the largest deposits of the ore are to be found in the Empire, have been forced to restrict their output. It is hoped to extend the market for these ores to the south, and by a reduction of freight rates and a more thorough utilizing of the inland waterways, to lay down the ore at the Don foundries for about \$3.84 per ton, a price only slightly higher than the local hematite ores. If the South can obtain the Ural ores at that figure the future of its iron industry is assured, and the local mill owners can view the export of their hematite ores to Germany with indifference.

THE uses to which diatomaceous earth are put are constantly increasing, and the methods of application are developing. Formerly employed solely for abrasive purposes, it soon became useful in the manufacture of polishing powders, soaps, etc.; but its abrasive quality is not its most valuable one. Its porosity makes it a good absorbent, and it is extensively used in the manufacture of dynamite from nitroglycerine. Being very light and a poor conductor of heat, it is valuable for use in the manufacture of packing for safes, steam-pipes, and boilers, and of fire-proof building materials. It also serves as a base for the manufacture of cement suitable for withstanding heat. It is a good filtering substance, and is so used commercially. Some of the earth from the Lompoc region is said to be used in the refining of beet sugar. In the Lompoc region, and also at Monterey, farther north on the California coast, it is used in the construction of buildings. The shale is easily quarried into smooth blocks.

* See papers of Van Hise, Emmons, and Weed for details of the processes, *Trans. A. I. M. E.*, Vol. XXX, 1900.

Cyanide Practice at the Homestake Mills.

Written for the MINING AND SCIENTIFIC PRESS
By F. L. BOSQUI.

Apropos of recent descriptions of filtering processes, including the Butters, Moore, and Ridgway systems, some account of present Homestake practice, compiled from notes taken on a recent visit to the property,

Precipitation-presses.

may be of interest. By way of preface, and to refresh the reader's mind as to the main facts, the Homestake plants at Lead, in the Black Hills of South Dakota, consist of six stamp-mills, containing an aggregate of 1,000 stamps, and crushing about 4,000 tons per day. The most interesting feature of the mill-practice is the amalgamation. Each battery is provided with four full-size plates, in series, each plate being 54 by 114 in. and $\frac{1}{4}$ in. thick. The first is plain copper, the last three are silver-plated. This addition of three silver plates, giving to each 10 stamps of the Amicus (240-head) mill, a total plate-area of 600 sq. ft., and to the other mills an average of 360 sq. ft. per 10 stamps, is a comparatively recent innovation, and has proved an excellent one, increasing the recovery by amalgamation approximately \$200,000 per year above the annual recovery when only one 12-ft. plate was used. The saving by amalgamation is between 70 and 75 per cent.

The leachable portion of the tailing from the stamp-mills (610 stamps), consisting mostly of ore from the deeper levels, is treated, after slime separation, at the Lead plant, known as Cyanide No. 1. This plant has a capacity of about 1,800 tons per day. The oxidized surface ore is crushed in the mills at the north end of the property (360 stamps) and the leachable tailing treated in the annex known as Cyanide No. 2, at Deadwood, four miles distant from Lead. This smaller plant handles about 800 tons per day. Both plants were designed and

installed under the direction of C. W. Merrill, who devised the process and who recently installed the filter-press slime-plant to be described herewith. The practice at Cyanide No. 1 has been well described by Mr. Merrill himself* and needs no further comment.

The system of slime separation in use at these plants has been criticized by some of the advocates of South African methods as less effective than the old pointed-box system. But at the Homestake, the choice of cone-classification has been emphatically justified by the results. An elaborate sizing was not necessary and was not attempted. Exigencies of first cost, space, labor, etc., precluded double treatment; and to make the enterprise profitable, it was essential that all the sand be treated as a separate product, and in one operation. To those familiar with the difficulty of obtaining, without re-handling the pulp, a uniform charge of hydraulically distributed sand that will leach rapidly, the appended figures will seem incredible.

The leachable sand has the following average texture:

Coarse (remaining on 100 mesh) 30%.

Middling (100 to 200 mesh) 32%.

Fine (passing 200 mesh) 38%.

Through this product the solution percolates at the rate of from 3 to 4 inches per hour.

When we consider that all the separate slime passes through 200 mesh, and that this product is in so fine a state of division that 90% of its value is extracted in six hours by filter-pressing, the merits of the Homestake classification system require no further emphasis. The cost of treatment at Cyanide No. 1 which Mr. Merrill gave in 1903 as 35c. has since been reduced to 26c. per ton. At Cyanide No. 2, the product treated is much lower in grade, averaging only 85c. per ton. This plant was the more recently constructed of the two, and is the more perfect, not only in its arrangement, but

Screw End of the Slime-press.

in its facilities for maintaining a low cost of treatment. A summary of the operating cost for six months is given on the next page.

I have mentioned the slime separation as a most interesting feature of these plants. Another novel feature is the periodic introduction of air into the pulp for the purpose of providing oxygen to the sub-sulphide of iron—one

*Trans. Amer. Inst. Min. Eng., New York meeting, 1903.

of the most troublesome constituents of the ore—and so maintaining the dissolving power of the solution, which would otherwise be robbed of its oxygen by the iron. Both of these big plants are remarkable for the order and neatness exhibited in every department. Operations have been reduced to so simple a system that they seem to be working automatically; yet if one glances behind the scene, he finds an able corps of assistants continually studying special problems, looking to the reduction of costs and increased efficiency.

From the two leaching plants, about 1,600 tons of slime have been run to waste, of an average value of between 40c. and \$1.20 per ton. In working out a method for treating this product, Mr. Merrill considered the various slime processes now in favor, but discarded them all as unsuited to Homestake conditions. In treating an 80c. slime, a system requiring the two operations of agitation and filtration in separate vessels was not to be thought of; and the only device in which treatment and filtration could be performed in one operation was the filter-press; but the cost of operating the old type of filter-press was prohibitive, and this condition led to the development of what is known as the Merrill press, which essentially differs from the old type in that it can

slime; the next department contains two large cone-bottom accumulation-vats; the next floor is occupied by the solution storage-vats and precipitation-presses; the next by the slime-presses; and the lowest by the precipitation-vats and dumps.

Two small vats are provided for slaking lime. Their contents are drawn as required to a screen-covered box where the undissolved lumps are separated. This box overflows into an agitator, from which the milk-of-lime is continuously discharged into the main slime-stream at the rate of 5 lb. lime per ton of slime. The two sludge storage-vats are 26 ft. diam. and 24 ft. deep with a 47° conical bottom. The discharge from the sludge-vats passes directly to the filter-presses under a pressure of about 30 lb. through a 10-in. main, which extends through the whole length of the press-building. Between each pair of presses this main branches into a longitudinal 10-in. distributing pipe, which in turn sends two 4-in. branches to each press. These small branches communicate with a continuous channel in the press at the centre of the top, 4 in. diam., by means of which the slime passes to the filter-chambers. Other channels are provided as follows: One at each upper corner, 2½ in. diam., for the entrance and exit of air; one at each lower

be discharged without drawing the plates and frames apart. Several good descriptions of the Merrill press and process have appeared in the mining periodicals and I shall not attempt here more than a brief account of the plant.

At the beginning, a 10-ton press with 4 by 6-ft. frames was installed for experimental purposes and was in use continuously for 18 months. In one run 131 charges (or about 5,000 tons) were treated, on which the following data are available:

Average value of slime before treatment, 91c.; after treatment, 10c. Extraction by assays, per ton treated, 90% or 81c. per ton. Recovered in precipitate, per ton treated, 91% or 83c. per ton. The treatment was simply lixiviation in the press, without agitation. Amount of solution used to leach 1 ton of slime, 0.73 tons; amount of water used for sluicing, 4 tons to 1 ton of slime; thickness of cake, 4 inches.

The large plant, recently started, is situated at Deadwood. The slime, after partial dewatering in cone-bottom clarifying vats, which reduces the proportion of water to solid, in the ratio of 3 to 1, is conveyed in two pipe-lines to the slime-plant, as follows: A 12-in. pipe carries it from Cyanide No. 1, a distance of 3¼ miles, at a minimum grade of 1½%; a 10-in. pipe carries it from Cyanide No. 2, a distance of 2 miles, at a grade of 1½%. The plant is built on a steep hillside and consists of five levels. The uppermost contains the apparatus for slaking lime and feeding it automatically into the stream of

corner, of same diameter, for entrance and exit of solution; and one large continuous channel extending along the centre of the bottom, by means of which the spent slime is sluiced out. This channel is 6 in. diam., and along its top is suspended a 3-in. pipe extending the length of the press. This pipe is provided with 92 nozzles, 1 in. long and ¾ in. diam., each of which delivers a stream into one of the 4-in. chambers, under a head of about 50 lb. By a special mechanism, a reciprocating motion is imparted to this pipe, causing it to revolve through an arc of 210°, so that each small nozzle plays against the compact slime-cake, removing the cake completely and cleansing the compartment in about 45 minutes. The discharged slime leaves the press through the crescent-shaped space between the 4-in. pipe and the 6-in. channel, the latter being sealed during the operations of filling and leaching.

The operations within the press consist of leaching with solutions of 0.1 and 0.04% strength, and the aeration of the cakes so essential to good extraction in the Homestake ore. The whole operation, exclusive of filling and emptying, occupies about 6 hours. At the time of my visit, (January, 1907), five of the 24 presses were in operation and working most satisfactorily; the remaining presses were partly set up and were being put into use as fast as the plates arrived from the factory. Under date of February 22, Mr. Merrill writes: "We are now treating at the rate of about 12,000 tons per month and will increase this by several thousand tons per month

until our full capacity of 50,000 tons is attained. Cost data are not obtainable yet, but will not exceed 25c. per ton for all items."

Mr. Merrill submits the following data for January, 1907 :

Tons treated.....	7,670	
Assay-value.....		\$7.85
Recovery in precipitate.....		0.68
Carried over in unprecipitated solution.....		0.09
Total recovery (equivalent to 90.1).....		\$0.77

At the present time (May 1) eleven of these presses are working continuously, and with results confirming those of the experimental plant given above.

I have already stated* what I conceive to be the limitations as well as the merits of Mr. Merrill's process. In all fairness it may be said that each of the filtering systems now in vogue possesses distinct merits of its own. The supreme test of the metallurgist in these days of many inventions is to select the *right* process for his purposes, that is, the one uniting the greatest number of advantages when applied to his special problem. Of Mr. Merrill's system it may be said finally and emphatically, that it is an established success, and will consequently have a wide range of usefulness. As for the installation itself, which will cost when completed, a half-million dollars, I question whether in the whole field of cyanidation, we shall find a more ingenious and original achievement, or one more conspicuously uniting metallurgical efficiency with perfection of mechanical detail.

COAL IN CHILE.—Traces of coal-bearing ground have lately been discovered to a considerable extent in Tomé. Preliminary surveys prove that there are veins of the richest coal at a depth of from four to six metres.

PRODUCTION OF COAL IN 1906.—According to statistics compiled for the United States Geological Survey by Edward W. Parker, the total production of coal in the United States in 1906 was 414,039,581 short tons of 2,000

Discharge From Two Presses.

The Great Open-cut of the Homestake.

lb., valued at \$512,610,741. These figures, compared with those of the preceding year, when the output amounted to 392,919,311 short tons, valued at \$476,756,963, show an increase of 21,120,240 short tons, or 5.4% in quantity, and of \$35,853,781, or 7.5% in value. Of the total production in 1906, Pennsylvania contributed 200,546,081 short tons, or 48.4% in quantity, and \$262,182,935, or 51.1% in value, the larger percentage in the value being due, of course, to the higher value of anthracite, which is produced almost exclusively in that State. The anthracite production of Pennsylvania in 1906 was 71,282,111 short tons, valued at \$131,917,691, while the bituminous production was 129,263,673 short tons, valued at \$130,265,244. The anthracite production of Pennsylvania in 1906 was 5,691,112 long tons (or 6,377,139 short tons) less than that of 1905, with a decrease in value of \$9,961,306, while the bituminous production showed an increase of 10,850,036 short tons in quantity and of \$16,871,731 in value.

But little information on mining coal and gold in China is obtainable. During the year the Imperial Chinese Railways opened a coal mine at Hsin Chiu, a place north of Kuangning district, but its output is unknown. Gold mines are reported to have been discovered in that vicinity. At Chinchow a coal mine is worked by native process. An attempt was made to introduce foreign machinery at this place, but for some reason or other the project failed. The Japanese have a mine at Wa Fang Tien that is reported to be of great wealth. Both coal and gold are mined.

Further surveys are being made to determine in a definite manner the class and quantity of coal likely to be extracted.

*MINING AND SCIENTIFIC PRESS, December 15, 1906.

Brazilian Diamonds.

There has been considerable increase in the movement of diamonds from the Diamantina district of Brazil to the United States, although the vast bulk of the output continues to go to Paris and London. The establishment of a concern for cutting and finishing the stones at Diamantina has led to a change in the course of export, and the contract of one of the American mining concerns to purchase the output of other concerns at Diamantina is likely to lead to a still further increase in the American imports. What the output of Brazilian diamond fields at the present time really is can not be given with any degree of certainty. Owing the policy of the State Government in its attempt to tax the stones on export, no records of the finds or of the sales are kept. A private record kept by a diamond mine owner in Diamantina shows that in one district of that field over 4,800 carats of stones were bought from the original holders from September 14 to November 14, 1906. This period was probably an average one, and the output of this particular territory therefore will average about 2,400 carats of stones per month. There are two other similar mining fields in the same country, and while the output of the two combined will not exceed that of the first-named district, it seems very probable that the total output of the Diamantina country at present is about 5,000 carats per month, worth on an average perhaps something over \$40 per carat for mine-run stones in the rough. The income of the Diamantina district from its diamonds at the present time is about \$200,000 per month. This output of the Diamantina diamonds is altogether the production of mining with native means and methods from the so-called *serviços*, which represents no faithful or effective test of the value of the country. These *serviços* are bands of workmen organized into effective squads, sometimes by a large number of workmen themselves agreeing to work together for a season and dividing the output, and sometimes by men with capital enough to hire men for a season, taking the output for themselves. In the dry season the river beds are worked; in the rainy season, the uplands. Rude sluices and wooden pans represent the machinery employed and there is no doubt that a large number of stones are missed in the process. Large numbers of stones are bought from Brazilians inhabiting the surrounding country, and there is no means at present of testing what mining property is worth or how much capital, time, labor, and expenditure the present output represents. Nor is there any means of telling how many people are actually engaged in whole or part time in the work. The mining companies now installing plants in the Diamantina country are almost altogether American. Practically all of them are engaged in getting in their dredging machinery and preparing for active work on a more or less extensive scale. The trouble, expense, labor, and time necessary to accomplish even the more simple tasks in this line can only be fully appreciated by those who have engaged in the work. Diamantina can now be reached in two days by fast mule-back from the end of the railroad, and in the course of a short time a public service of diligences will offer more improved means of making the journey, but the difficulty of transporting heavy machinery in such sections as a mule can carry over mountainous country is apparent.

IN GERMANY, the reopening of several long-abandoned tin mines throughout the Erz Mtn. now seems assured. One mine at Ehrenfriedersdorf is now working and expects to give employment to 200 miners before the summer is over.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The rock sent by R. McM., of Bouse, Arizona, is an Andesite.

A specimen of Carborundum was sent by E. L. B., from Pony, Montana.

Y sends a specimen from Reno, Nevada, which is largely Calcite, Chlorite, and Pyrite.

The specimen from Wallace, Idaho, marked A is Andradite Garnet stained with Malachite.

R. D. sends from Wickensburg, Arizona: A, Andesite; B, Andesite; C, specular Hematite in quartz.

The rosin-yellow mineral in the specimens from J. A. McL. of Goldfield is Sphalerite; the dark gray mineral is Galena.

A fragment of Basalt with seams of specular Hematite was sent from Silver City, New Mexico, by C. H. L. It carries no tin.

The specimens from Olalla, B. C., marked B. C. O., are: No. 1, Wollastonite; No. 2, Epidote and Andradite; No. 3, Gabbro.

Two specimens of crushed and altered rock, now largely Calcite, Quartz, and Hematite, were sent from Sinaloa, Mexico, by A. W.

The specimens sent from Campanillas, Mexico, by E. H. H., are: No. 1, Cosalite, a sulphide of lead and bismuth, with pyrite and chalcopryrite; No. 2, Andesite; No. 3, Andesite.

A. E. I., of Ashland, Oregon, sends: No. 1, Sericite Schist; No. 2, Pyrite, Chalcopryrite, and Covellite; No. 3, Pyrite and Chalcopryrite; No. 5, mineralized Dacite. We would hardly expect the schist to be a copper ore.

T. W., of Great Falls, Montana, sends: No. 1, Quartz with pyrite and chalcopryrite, stained with malachite and limonite; No. 2, Galena; No. 3, Quartz Porphyry; No. 4, Feldspar; No. 5, Calcite, Quartz, and Limonite; No. 6, Calcite.

The specimens sent from Fairview, Nevada, by J. A. P., are: No. 1, Rhyolite; No. 2, Turquoise; No. 3, Andesite; No. 4, Rhyolite; No. 5, Andesite; No. 6, Andesite; No. 7, Andesite; No. 8, Andesite; No. 9, Andesite; No. 10, Chert; No. 11, Rhyolite; No. 12, Rhyolite; No. 13, Rhyolite; No. 14, Quartz.

THE terrible disasters which have recently occurred in the coal mines of Germany and France have directed the attention of scientists, especially in the former country, to introducing methods of protecting the miners against a recurrence of such calamities, or at least of diminishing, as far as possible, the loss of life. One measure contemplated is the construction of safety chambers shut off from the rest of the mine and protected against explosions. A conduit of compressed air is introduced into these excavated rooms, and should the conduit be destroyed, vessels, or bottles filled with oxygen, stored in these chambers, shall supply the necessary air. Preparations are already being made for the introduction of these arrangements in the mines in the region of the Saar.

The Geology of the Coffee Creek Mining District.

Written for the MINING AND SCIENTIFIC PRESS
By NORMAN S. STINES.

This district lies in the northwest corner of Trinity county, California. It is a granite area flanked on all sides by a coarse-grained gabbro, parts of which have been changed, by the alteration of the pyroxene, to serpentine. The granite is probably batholithic in occurrence and is closely related to other granite areas that outcrop to the north and west. This granite area is approximately three miles wide by nine miles long; the longest dimension is north and south. The gabbro flanks this on all sides.

The granite varies in texture from a rock of fine grain, at the contact with the gabbro, to one of coarse grain at some distance from this contact. It contains quartz, feldspar, biotite, and hornblende with the usual accessory minerals. The biotite occurs sparingly. Coursing through the granite in all directions, and standing approximately perpendicular, are many aplite and pegmatite dikes.

The term gabbro is here used in its broadest sense as applying to that class of granitic rocks which are very basic. Locally the gabbro varies from a rock carrying mostly plagioclase feldspar and small amounts of pyroxene to one carrying practically only pyroxene; in other words, all gradations from anorthosite through gabbro to pyroxenite or peridotite.

The anorthosite and gabbro are coarse in grain; some crystals of plagioclase and pyroxene being as much as two inches long and three-eighths of an inch wide. In many cases the ferro-magnesian mineral has been altered to hornblende and serpentine, and in every case the surface rock (by oxidation of the iron) has a reddish color. Unaltered pyroxenite or peridotite is rare, but in their stead is found serpentine. These anorthosites, gabbros, and peridotites do not occur as separate rock-masses but rather as differentiations of the same mass. It is due to the peridotite being more prone to alteration that we find areas of serpentine.

The veins lie wholly in granite, wholly in gabbro, or they roughly follow the contact between the two formations. In one case at least a vein strikes through the granite and continues into the overlying gabbro. The veins are numerous and for the most part strike from N 20° E to N 37° E. In all but one case they dip from 60 to 87° southeast. In that one case the dip is to northwest, but sufficient depth has not yet been gained to be sure that the dip is not a false one due to the creep of the surface. These veins vary in width from mere stringers to 12 ft. In a few instances there are cross-stringers connecting the parallel veins. The distance between parallel veins varies from a few feet to several hundred. It might be said that there are several lodes running through this area.

The quartz constituting the veins may be frozen to both walls, frozen to only one or free from both walls with a gouge on each. Those veins that are frozen to one or both walls plainly show their genesis. They are due to a replacement, along a line of fracture or zone of shearing, of the crushed ferro-magnesian minerals by pyrite; the alteration and kaolinization of the feldspars and the silicification of the sheared zone. It is not uncommon to find in one piece of ore all grades of material, namely, the unaltered granite; the granite in which the outlines of the ferro-magnesian mineral can still be seen, although they are completely replaced by pyrite; that in which all traces, save texture, of the original granite has disappeared; and the white sulphide-bearing quartz that in no way resembles the granite it has replaced. In the veins that are frozen to neither

wall the origin of the ore cannot be so easily traced.

These veins are continuous for long distances; one can be traced by its outcrop for 4,000 ft. Numerous faults, having an east and west throw occur, but in no case does the throw exceed a few feet.

The ore-shoots are found distributed along the strike of the veins. Not sufficient work has thus far been done to determine the dimensions of the shoots and what controlled their deposition. But the following facts stand out clearly:

1. The ore-shoots come to the surface. Their position is indicated by the gold found in the overlying soil. It is often necessary to go through this soil and decomposed granite for as much as 25 ft. before the ore is found in place.

2. The shoots dip to the north at an angle varying from 57 to 85 degrees.

3. They have been formed in the swell of the vein. Where the quartz pinches, the assays drop; in most cases the best ore is found where the vein is the widest.

4. In one case, at least, the north side of the pay-shoot is controlled by a fault and the south side by an abrupt change in the strike of the vein.

The ore, as outlined above, is quartz or some stage of altered granite impregnated with sulphides and other gold-bearing minerals. The economic minerals are galena, chalcopyrite, iron pyrite, sylvanite, and petzite. Sylvanite and petzite are sparingly disseminated throughout the ore, but at times they are locally found in sufficient amount to make bonanza ore. The quartz is a hard compact variety but cavities lined with well formed quartz crystals are sometimes found.

As mined and milled the ore is classed as oxidized and unoxidized. The unoxidized ore is that described above and rarely, if ever, carries free gold, although at times it assays hundreds of dollars per ton. The oxidized ore is found only in the upper workings and always carries free gold with sulphides. The amount of sulphides increases with a corresponding decrease in the free gold as depth is attained. In the oxidized zone there have been found lenses of rich ochre in the regular milling ore. In this ochre the gold is very fine, this being probably due to the accumulation of finely crushed vein-matter, thoroughly oxidized. The extreme richness is probably due to a secondary concentration as the vein was eroded. There is still another occurrence of rich oxidized ore that cannot be explained in this way. The rich ore in this case consists of large crystals of hematite, which are pseudomorphs after pyrite. These are an inch long and are fractured, the fractures being filled with quartz. The crystals carry a great deal of fine gold and this class of ore assays as high as \$6,000 per ton. It seems to be plainly an oxidation of a rich auriferous sulphide. This shoot has not been followed to the unoxidized zone as yet and until that has been done the correctness of this explanation cannot be established. There was one occurrence of large pieces of gold in an oxidized material which suggested that it was derived from the oxidation of large crystals or aggregates of tellurides. The ore as stoped varies in width from 18 in. to 12 feet.

There are no difficult problems connected with the mining of the ore. The walls stand exceedingly well and a minimum amount of timber is required. All stoping is at present done by hand but the unoxidized orebodies would be almost ideal for the use of machine-drills. Any necessary sorting is done underground and the waste is used as filling.

From the nature of the ore, it is obvious that the metallurgy is not simple. All ore found in the oxidized zone yields from 3 to 7% of its gold by amalgamation, the remainder being extracted by concentrating with

subsequent cyanidation of the concentrate and tailing. This treatment gives an extraction of from 82 to 87%, but it is not successful for the unoxidized ore, from which it extracts only 50 to 60%. The most successful mode of treatment for this ore is crushing for concentration only; concentration; roasting followed by re-crushing, then cyanidation of the concentrate, followed by bromocyanide treatment, after sliming, of the tailing.

Dry-crushing followed by roasting and cyanidation give a good extraction. Either of these schemes of treatment should give economic results. The former method was tried on a working scale by a small plant and from tests extending over a period of three months an actual bullion-recovery of 89% was obtained. As yet no practical application of the last scheme has been made. The total absence of lime and other chlorine-absorbing elements suggests the possibility of a successful scheme of treatment by chlorination after roasting.

This district is well favored with respect to wood and water. Most of the mountain slopes are heavily timbered with red fir, sugar, and yellow pine, and the low benches carry an abundance of oak and maple. Streams of water are plentiful. The fall is such that on the larger streams one to two miles of ditch is sufficient to give a drop of 80 to 120 ft. In the smaller streams heads of 100 to 700 ft. can be obtained with short ditches and pipelines. All mines thus far equipped use power derived from the water under pressure. In winter the abundance of snow causes much trouble along the ditches and flumes; by covering them where slides are likely to occur, together with sufficient and frequent watching, this trouble can be eliminated and water-power made available throughout the year.

DREDGING IN QUEENSLAND.—Great activity continues to be shown in dredge-mining. The total quantity of material treated during 1905 by bucket-dredging, pump-sluicing, and jet-elevating, according to the report of the Mines Department, was 13,150,945 cu. yd., as against 10,192,400 cu. yd. in 1904. The gold obtained amounted to 72,953 oz., as against 55,257 oz. for the previous year, the average yield of gold per cubic yard treated being 2.6 gr., as against 2.37 gr. in 1904. The quantity of stream tin won during 1905 was 94 tons 16 cwt. 1 qr., valued at £8,428 7s. 6d. The average quantity of material dealt with per week by each dredging plant was 4,802 cu. yd., and the areas treated during the year aggregated 479.5 acres, the average yield of gold per acre being 152.1 oz. The weekly yield of gold won by each plant averaged 26 oz. Altogether, 82 dredge-mining plants, comprising 26 bucket-dredges, 49 pump hydraulic sluices, 6 jet-elevators, and 2 rotary hydraulic plants, were in operation. The number of men employed in dredge-mining during the year was 2,040, an increase of 540 over the number in 1904. The amount expended by the companies in wages, fuel, and maintenance for the year was £217,164, as against £104,000 in 1904. The sum paid in dividends during the year was £43,412. On December 31, 1905, the number of new plants in course of construction was 38.

AT CAPE BRETON there are immense collieries being worked under the ocean. These submarine mines cover a thousand acres and are being increased steadily. The mines are entered at the shore and the operators follow the vein beneath the water for more than a mile. It might be expected that the weight of the water would force its way into the mine, but a sort of fire clay lines the submarine roof of the mine, and the sediment above this is held in place and packed down by the water pressure until there is not a crevice nor a drop of water from overhead.

A Portable Acetylene Mine-Lamp.

Written for the MINING AND SCIENTIFIC PRESS
By EDWIN O. DAUF.

The use of acetylene lamps is more common in Mexico than in the United States, due, probably, to other illuminants costing more here than in the States.

Mexican mechanics often exhibit much ingenuity, the result being that various types of home-made acetylene lamps can be found around mines and other places. Having seen one of these lamps in successful operation in stopes and poorly ventilated places where an ordinary candle or torch would not burn, I have made a drawing of it in the hope that it may prove of value to others that are in need of a cheap light which will burn under unfavorable conditions. The type of lamp herewith described was used in one Mexican mine continuously while air-connections were being driven. Acetylene requiring less oxygen than other illuminants, it was found that faces could be worked where an ordinary lamp or candle would not burn. In large stopes it also proved satisfactory, since the amount of light furnished by one lamp was greater than that of a number of candles or a torch and, the lamp being portable, could be moved from place to place, wherever light was most needed. The lamp can be cheaply constructed; any tinsmith or ordinary mechanic will have little difficulty in making one out of ordinary galvanized iron and a few pieces of pipe.

Fig. 1 shows the lamp assembled and the other drawings show all the necessary details. Referring to Fig. 1, the method of charging the lamp is as follows: The rubber tubing is first disconnected and the cover *f* is removed; the gas-drum *a* containing the carbide-drum is now removed and the cap *b* unscrewed. The carbide-drum can now be slipped off and is filled with about 2 lb. calcium carbide, which should be in rather large lumps. The carbide-drum is now put back into place and the water cylinder *c* is about half-filled with water; now carefully lower the gas-drum into the water, being careful not to allow the carbide to touch the water until the cover *f* is replaced and the rubber tubing is connected. The small valve in the pipe leading to the purifying-drum may now be opened, allowing the air to escape through the drum and gas-jet. As soon as the air has all escaped the drum containing the carbide will come in contact with the water and acetylene gas will be generated. This gas enters the gas-drum *a* and finds its way into the pipe by way of the small hole *d*, and passes into the purifying-drum which is packed with cotton-waste, which will take up any small particles of dust. From the drum the gas passes into the pipe fitted with a Stewart patent gas-tip.

The lamp is self-regulating, for as soon as more gas than can be immediately used is generated, the pressure of gas will raise the gas-drum *a* and, the carbide-drum, being attached to other drum, will be lifted out of the water and no more gas will be generated. As the gas is used up, the gas-drum with the carbide-drum will settle down into the water again and more gas will be generated. The lamp being self-regulating, little attention need be paid to it after charging and starting.

An experimental gas turbine has recently been constructed in France, which showed an efficiency of 18%. The turbine is of the impulse type, the casing being lined with refractory material. Gasoline is used as fuel, and is fed under pressure through an expanding nozzle, being ignited electrically and generating a temperature of combustion of over 3,000° F. The blades were cooled to a certain extent, while rotating, by low-pressure steam admitted into the casing.

Portable Acetylene Lamp. Made of Galvanized Iron.

The Mines and Agriculture of Roman Britain.

Written for the MINING AND SCIENTIFIC PRESS
By ALEXANDER DEL MAR.

The scientific attainments and perseverance of a woman are bringing to light a knowledge of the ancient history of Britain which hitherto has remained a sealed letter. A few months ago, while the workmen upon her estate near Silchester were making some excavations, Mrs. Selwyn noticed the presence of certain ancient Roman and Anglo-Saxon relics in the earth, which she thereupon caused to be removed with particular care and thoroughly sifted. The upshot has been an immense collection of valuable monuments of the past, which, taken together with previous finds, furnish us with a key to the ancient system of mining, agriculture, highways, and fairs. Without further reference to authorities, I shall endeavor to give as complete an account of results as possible.

It appears that after their conquest of the island the first industry to which the Romans applied themselves was gold and silver mining and that while these industries were being prosecuted, the whole island was laid out in a series of military highways, constructed by the Roman provincial government, and of such an enduring character that most of them are in use at the present day. On account of their superior knowledge of mathematical instruments, these roads are believed by some writers to have been planned by Greek surveyors. The military highways were usually made 15 or 16 ft. wide, and as straight as possible. In crossing marshy lands they were laid upon piles driven into the earth. Where rivers could not be conveniently forded, they were bridged, at first with wooden structures, afterward with stone ones, like that across the North Tyne, the magnificent abutment of which, first laid bare in 1867, excites the admiration of the modern engineer. All of these highways have been identified by antiquarians either by means of the Antoninus 'Itinerary' or by the manuscript notes of the legionary commanders, or the mile-stones placed upon the road by the Romans, for some of these are still remaining where they were placed. There have been found 56 milliaris, or Roman mile-stones. They date from 120 to 136, that is, from Hadrian to Constantine the Younger. When the highways were completed and connected with the smaller roads, from the mines, farms, and workshops, Britain possessed for the times a perfect means of communication between every industrial centre, the manufacturing towns, and seaports. In many parts of England, for example, in the vicinity of Cheddar, the modern roads follow the course of the Roman.

Before this period the Imperial Government had constructed a series of great highways, which radiated from the capital in Italy, and penetrated every province of the Empire. Guard and post-houses, the latter provided with relays and horses, ready for immediate use, were stationed upon all of them. They were continually patrolled by a rural police, so that the traveler, merchant, or courier could travel throughout the Empire with safety and speed. The post traveled at the rate of about 100 miles per day. This system was applied by Augustus to Italy, and extended by Tiberius to the provinces. After the Anglo-Saxon invasion, no such system of patrol and posting existed again in Britain until the reign of William IV. The Imperial highways to connect with Britain ran from Italy through Gaul, to Calais, and Boulogne, where they were connected by sailing packets with the roads in Britain. Here the highways were provided with patrols, and posting-houses, as on the Continent.

Gloomy and repelling as the climate of Britain must

have appeared to the Roman colonists, the care that they took to bring its wild lands into cultivation proves that they soon discovered the many advantages it possessed, to compensate them for the absence of the blue skies and serene weather of their native land. Here let it be remarked that the exclusively military character which history has stamped upon the Romans is most misleading. The Romans were also essentially an agricultural people, and we owe to them the knowledge and preservation of nearly all the edible plants and fruits now in use.

It matters not when the legend was invented, which the English still commemorate in Rogation week, and the switching of boundaries; it is sufficient that it obtained credence in the time of Varro, Virgil, and other ancient authors. According to this legend, Romulus established or continued upon a firmer basis the *Fratres Ambarvales*, or the 12 ambling or swaying priests, of Maia, whose functions included supplications (*rogatio*) for favorable crops, the celebration of thanksgiving after harvest, and the marking of agricultural boundaries. All these functions, which were actually performed by officers chosen from the most distinguished families of Rome, evince the agricultural character of the Romans. The careless cultivation of land was an offense, which in the early days of the Republic, came under the cognizance of the censors, and, as Cato informs us, to be called a good husbandman was to receive the highest of compliments. Of the 20 tribes into which the Roman people were divided by Servius Tullius, 16 were rural, and only four were urban; the former holding the highest rank. The noblest families among the Romans, as the Fabii, Pisones, Lentuli, Cicerones, etc., derived their names from agricultural avocations; many of them most eminent men, as Cato, Varro, Virgil, Pliny, Columella, and Palladius, wrote treatises on the subject; and as to implements of husbandry, barring the mower, harvester, and steam-plow, they were but little inferior to those in general use throughout the world today.

That the agricultural character of the Romans did not desert them in Britain, is attested not only by the variety of plants they introduced and cultivated, but also by the extent of forest and marsh land they reclaimed; and although the rough labor was done by captives, it would be unfair to withhold from their conquerors the credit of teaching them the valuable lessons in tillage and horticulture, which, through them, have descended to the modern world.

Roman aptitude for agriculture is evinced by the fact that, even at this distant period, the fruit and vegetable trades of the Western world are largely in the hands of Italians; and in many countries, not merely the trade, but also the cultivation. Even so far west as your San Francisco, the Italians are the principal cultivators and merchants of edible vegetables. In London, from the largest wheat merchants, who are Italians, to the ancient costermonger class, who are supposed to conserve a strain of Roman-British blood, the same tendency is observed. In New York, the vegetable and fruit trades both wholesale and retail are largely in the hands of Italians. "The Romans were farmers, and they loved farming."

All the vegetable products of Italy, susceptible of being cultivated in the colder climate of Britain were introduced into that country by the Romans. Cereals, fruits, edible vegetables, flax, and even flowers, were thus transplanted, or disseminated. The Romans brought into Britain the apple, pear, plum, peach, apricot, cherry, currant, gooseberry, and grape. The apple was grafted into the native costard, hence the modern term 'costermonger,' for an apple or fruit-vender. The walnut tree is indigenous to, and still grows wild in, Persia and

Afghanistan, whence, at about the beginning of our era, the Romans introduced it to Italy, and afterward to Gaul, from which country it was transplanted to Britain, and thus its fruit came to be called the gaul-nut or walnut. The Romans also introduced the willow, or box-tree.

When grape vines were introduced into Britain it was not permitted to cultivate them for the purpose of making wine, for fear that it might curtail the demand for the wines of Italy. An edict of Domitian on the subject is still preserved. A policy similar to this one was afterward pursued by the Spaniards in America. About the year 276 the Emperor Probus reversed this policy, by encouraging the planting of vines and making of wine in Britain.

Turnips, carrots, parsnips, cucumbers, radishes, onions, gourds, beets, cabbages, endive, lettuce, asparagus, beans, peas, mustard, parsley, and many other vetches and herbs, were planted by the Romans in Britain. Their gardens were filled with roses, lilies, heliotropes, and other sweet-scented flowers, excellent enough to be known and mentioned in Rome. Britain is also indebted to the same source for all its useful grasses, among others lucerne, the medica of the ancients, and the alfalfa of the Moors, Spaniards, and Americans. Its ancient name reveals its Oriental origin.

Agricultural fairs are often erroneously attributed to the medieval ages. As a matter of fact they were held in the remotest times. Fairs at Tyre and the articles sold in them are mentioned in Ezekiel, Chapter XXVII. The Egyptians, Etruscans, and Romans, both during the Commonwealth and Empire, all held fairs. Trajan, Hadrian, and Antoninus established annual fairs at Lyons and elsewhere. With the Romans, fairs were a religious institution, the profits of which were consecrated to the support of the temples, within whose grounds, and under whose auspices, weekly fairs were held every *nundinum*, or, as we would say, every Sabbath day. This day, which with us is one in seven, but with them was one in nine, was also called *feria* or fair day, and the days of the week were reckoned and named from it, as *prima feria*, *secunda feria*, and so forth. At the Roman fairs agricultural products, wares, and slaves were sold, servants were hired, leases were renewed, and numerous other important affairs negotiated.

THE GOLD YIELD OF VICTORIA.—Victoria can claim to be one of the richest gold-bearing countries in the world. From the time of the first gold discoveries, in 1851, to December 31, 1905, the amount of gold won amounted to 68,367,403 oz. gross, valued at £273,236,500. The yield of gold for the year 1905 was 810,050 oz. gross, or 747,166 oz. fine, worth £3,173,741. There was a decrease of 10,967 oz. as compared with 1904. Of the several gold-fields districts, Bendigo was first with 212,465 oz. Ballarat comes next with 145,331 oz. Beechworth was a good third with 133,587 oz. Castlemaine had 90,205, Maryborough 85,768, Gippsland 73,633, and Ararat and Stawell 23,651 oz. respectively. The official report of the Mines Department states that the largest increases in 1905, as compared with 1904, are those of Castlemaine and Beechworth districts, with 13,035 oz. and 11,002 oz. respectively, the improvement in each case being almost entirely due to dredge mining. In two other districts, Gippsland and Maryborough, there were also increases, in the former of 6,912 oz. and in the latter of 619 oz., over the yields of the previous year. In the three remaining districts there were decreases. Bendigo showed a decline of 30,415 oz.; Ballarat had 3,642 oz., and Ararat and Stawell 8,930 oz. less.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

A parol grant of mining privilege on lands is a mere license, and is revocable at will, and conveys no title to any ores not severed and reduced to possession before such revocation. The expenditures of moneys in mining under a parol license adds nothing to the grant.

McCullough v. Rains (Kans.), 89 Pac. 1,041. (April, '07.)

Where one mine-owner acquired a right to drive a tunnel through the mining claims of another, which divided the veins of such second person, such second person did not thereby acquire the right to use such tunnel to work his own veins, on the theory that the first person's condemnation had been made for a public use, there being neither allegation nor proof of necessity for such common use, nor that the second party could not proceed to condemn a right of way for a tunnel to be used for his own purpose.

Headrick v. Larson, 152 Fed. 93. (Feb. '07.)

Where the vendor had completely performed a contract for the purchase of an interest in certain mining claims and the purchaser had almost completely performed his part of the agreement, prior to his repudiation thereof, it was held that such performance was sufficient and effective to take the contract out of the statute of frauds.

Ferguson v. Blood, 152 Fed. 98. (March, '07.)

An agreement in a lease by which the lessee agreed to pay to the lessor a specified sum per annum for ore mined during the life of the lease, as a minimum royalty for the demised property, without reference to the quantity of ore actually mined, and providing that all rents and royalties agreed to be paid could be deemed and treated as rents reserved upon contract by the lessor, was held an absolute undertaking to pay the stipulated annual sum. And a clause providing that on failure of the lessee to make the payment of the royalties or to develop the property, it should become forfeited and utterly void, did not sufficiently manifest an intent that it should be optional with the lessee to develop the property and to pay the rent or not, as he might see fit, as the clause of forfeiture was intended for the benefit of the lessor.

Lawson v. Williamson (W. Va.) 57 S. E. 258. (April, '07.)

On appeal the Court refused to examine the evidence and determine as a matter of law that a miner was guilty of contributory negligence, or that he assumed the risk of the danger, where the evidence showed that the miner was injured while taking from the mine a load of coal, by reason of the sagging of a beam supporting the roof of the entry at a place known as a 'horseback,' where it was also shown that the entry at such horseback was dark, and that the only way anything could be seen was by means of artificial light, and where it was also shown that the miner was required to hold the loaded car back to prevent it from running on to the mules, and that he was required to look ahead to see that the track was clear of obstruction, although the evidence showed that he had been driving in the mine for three years and in the particular entry for two months, and that his duties required him to pass under the place where he was injured from fifteen to twenty times a day, and in the absence of any positive evidence that he had actual knowledge of the sag in the roof at such horseback.

Jones & Co. v. George (Ill.), 81 N. E. 4. (April, '07.)

In an action for the death of a miner while descending into a mine, by reason of the breaking of the cable attached to the bucket in which he was being lowered, the question of whether the operator of the mine was negligent in furnishing a defective cable was for the jury to determine, and the determination of the jury that he was so negligent, would not be disturbed by the Court on appeal.

Owen v. Retsof Min. Co., 104 N. Y. S. 37. (May, '07.)

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

APPARATUS FOR SINTERING FINE ORE.—No. 853,433; John G. Bergquist, Chicago, Ill., assignor to American Sintering Company, Chicago, Ill., a Corporation of Illinois.

In a sintering furnace apparatus, the combination of an upper tubular furnace body section movably supported to rotate upon its longitudinal axis and inclined from the horizontal, a lower furnace body section having its receiving end arranged in proximity to, but offset below, the delivery end of the upper section and also movably mounted to rotate about its longitudinal axis and inclined from the horizontal, an upright housing within the upper part of which the delivery end of the upper section extends and within the lower part of which the receiving end of the lower section extends, a removable closure in the wall of said housing opposite the delivery end of the upper section and through which access to the latter may be had, and an inclined movable chute board extending across the interior of said housing from a point below the delivery end of the upper section to the lower side of the receiving section, and an opening in said housing opposite the receiving end of the lower section, through which access to the latter may be had when the chute board is moved.

MINER'S LAMP.—No. 853,078; Ralph L. Graves, Sumpter, Oregon.

A wick tube constructed of a series of wires, collars adapted for holding the wires in circular arrangement, and a series of extension wires.

TUYERE CONSTRUCTION.—No. 849,539; Ulysses A. Garred, Anaconda, Mont., assignor to Charles H. Repath Anaconda, Montana.

In combination with a wind-box having a series of terminally recessed flanges distributed along its outer walls, hollow necks connecting the flanges to the walls of the wind-box, ribs disposed in pairs on opposite sides of the recesses and extending from the flanges to the wall of the wind-box, tuyeres having correspondingly recessed flanges adapted to engage the flanges of the wind-box, and hinge-bolts suspended between each pair of ribs and passed through the recesses of the respective flanges.

STAMP-MILL.—No. 855,284; George Coon, Mount Vernon, Washington.

In a stamp-mill in combination, an outer tank, an inner tank disposed therein, a plurality of hammers disposed in said outer tank and surrounding said inner tank, a centrally disposed chute, a cone disposed within said inner tank and adapted to deflect ore falling thereupon toward said hammers, said inner tank having openings near said cone through which the said ore may pass.

ORE SEPARATING AND CONCENTRATING MACHINE.—No. 853,917; William P. Clifford, Iconium, and William W. Rankin, Ottumwa, Iowa.

An ore separating machine, consisting of a suitable frame provided with side and end walls, a laterally and longitudinally inclined supporting board or plate adjustably mounted therein, a slidably mounted shaker-plate mounted on said supporting-board or plate, an adjustably mounted plate secured above said shaker-plate and affording an air-passage, said supporting-board or plate being provided with an opening or passage at its side and end, inclined chutes mounted beneath said openings or slots, and means for operating said shaker-plate.

FOREHEARTH.—No. 856,616; Charles M. Allen, Lo Lo, Mont.; assignor to Ralph Baggaley, Pittsburg, Pennsylvania.

A forehearth having its walls of a size, weight, and mass that will produce and maintain an interior skull of chilled metal forming a heat non-conducting lining when the forehearth is charged and capable of retaining sufficient heat to prevent increase in the thickness of the skull.

Editorial.

ELECTRICAL SMELTING OF IRON ORE is undergoing trial in California. During the past week a 25-ton smelter has commenced operations on the Pitt river in Shasta county. The Heroult process is being used and electricity is furnished by the Northern California Power Company, the president of which, Mr. H. H. Noble, is the moving spirit of this enterprise. The iron ore is a clean magnetite from a deposit situated on a ridge between the McCloud and Pitt rivers. The distinctive feature of this large-scale experiment is that the furnace is operating under a three-phase 60-cycle alternating current. In our next issue we shall publish a complete report of this important event.

NO BETTER APPOINTMENT could be made than that of Mr. Frank A. Leach to succeed Mr. George E. Roberts as Director of the United States Mint. Mr. Roberts becomes president of a bank at Chicago. Mr. Leach has been superintendent of the San Francisco Mint, where he exhibited unusual resourcefulness and loyalty at the time of the earthquake-fire. Apart from that episode, he has won a reputation as a faithful and efficient Federal officer. It is an appointment in which politics—especially our peculiarly dirty local kind of politics—play no part. We congratulate the administration at Washington in their choice and we wish Mr. Roberts a long and useful term of office.

THE peso is not a dollar, and the addition of the suffix Mex. to the latter is incorrect because the unit of coinage in Mexico is the peso. Much confusion has been caused by this misuse of terms, as all can testify that have had business south of the Rio Grande. Unfortunately the dollar sign is in general use but that for the peso is almost unknown, although it is employed in the Philippines. We intend to use it and have had the necessary type cast for us. When you see \$10 in this Journal you will know that is ten dollars and when you see P10 you will know that is ten pesos, that is, about half as much.

CARD SYSTEMS of accounts are a comparatively new feature of systematic mine management. They are being adopted, under various forms, at most American mines. It is likely that the detailed description given by Mr. R. S. Handy in this issue will be of immediate service to several managers. It is published with this purpose. We have previously published articles on this subject by Messrs. Walter S. Brown and Horace G. Nichols, besides one by Mr. Philip H. Argall on metallurgical accounts.

A STATEMENT is going the round of the non-technical press that a lake of quicksilver has been

discovered in the State of Vera Cruz, Mexico. We wrote to a distinguished Mexican geologist and he replies saying that he has just returned from the region specified. The whole thing is a yarn.

CABLE ADVICES state that dynamite outrages have occurred at Johannesburg as an incident in the strike of white miners. Attempts were made to destroy the shafts of the Cason and Modderfontein mines. This is serious, but we expect to see prompt arrests and swift punishment, for in these matters the Transvaal Government is likely to set a good example. No reign of terror, such as existed in Idaho and Colorado, will be permitted. The law is supreme because it has not been paralyzed by local politics.

MAIL ADVICES bring accounts of the further slump in Kaffirs—that is, South African mining shares—by reason of the attitude of the Transvaal Parliament, which is dominated by the Boer party. A motion condemning General Botha's policy was badly defeated and it is clear that the Chinese coolies will be repatriated when the existing contracts expire. There is a hope of Kaffirs being obtained to replace them, but this is vague. The mine managers realize that the brief era of Chinese cheap labor is fated to end abruptly and they set no store by the promised supply of Basutos, Kaffirs, and low-priced white men. The Boer policy evidently is to use the mines for the benefit of the country, and the people resident there; they refuse to consider the deposits of gold as being merely a means of enriching speculators in Europe. It is annoying to shareholders, but it is a selfishness not wholly unenlightened.

THE VAGARIES of promotion are varied. From New York come three recent examples. Thus, W. C. Greene got a timber concession for a song from the Mexican Government and sold half of it to the copper company of which he was president for \$1,250,000 with the further proviso that the copper company was to buy \$1,000,000 worth of lumber annually for 25 years. Grant Hugh Browne organizes the United Cobalt Exploration Co. to buy the Gillies Timber Limit, and when the Canadian Government refuses to sell it at his price, he invests the funds of the Exploration Company in purchasing other claims at Cobalt. He states that the money is not lost and that the vendors offered to refund it to the company. Another promoter has chartered a train to take speculators to Cobalt. It is to be a free trip, that is, you put up \$1,000 in cash before you start and this gives you the right to invest your money in 2,000 shares of stock. If your investigation does not prove the value of the mine, you will get your money back. Probably. On the return journey the train will stop at Niagara Falls and the shareholders will see some real water.

DIRECTORY OF DIRECTORS is the title of an annual guide-book giving a list of the leaders in corporate finance, together with their multifarious positions of supposed trust. William H. Newman is first

with 119 directorships as against 106 last year, and F. D. Underwood is second, being 80 times a director as compared to 72 a year ago. W. K. Vanderbilt is on 73 boards, E. V. Rossiter on 69, J. P. Morgan on 59, James Stillman on 57. Chauncey M. Depew, who was the champion multi-director two years ago, drawing fees from 73 companies in 1905, is now credited with only 64; and it is evident that he is no longer regarded as a respectable dummy. There are 12 men that serve as directors of more than 50 corporations. In contrast to these, John D. Rockefeller is a director of one company only. It is not necessary to emphasize the absurdity of the idea that a man can serve faithfully as a trustee in fifty enterprises nor to show the lack of conscience exhibited by men who accept so many responsibilities. In most cases the social engagements of these men occupy a noteworthy portion of their time, so that their attention to business affairs is necessarily limited. The 'Directory of Directors' may be considered as giving a list of the men that fail to recognize that a director is a trustee and not a figure-head with special privileges. John D. Rockefeller, bad citizen and chief pirate as he is, sets an example in his devotion to a single business and the only regret is that his work is so distinctively anti-social.

The Study of Ore Deposits.

THEORIES of ore deposition are always interesting to those engaged in mining; indeed, it is fair to say that as regards the attempt to explain occurrences of ore no one is so prone to theorize as the miner himself—the prospector, the drill-man, and the operator. Professors are popularly credited with dreaming scientific dreams, but it is a fact that you will hear more theories on ore deposition in a mining camp than in a class-room, and while it may not be wholly true that the freedom of conjecture increases with the scantiness of scientific observation, it is certain that the vitality of the discussion is intensified among those to whom such theories are no academic matter but a real guide to exploration. Among the unscientific the facility for theorizing is increased by the lack of knowledge; the constructive imagination that is untrained loves to be free from the brutal restraint of facts. For this reason the study of ore deposits has suffered; despite the intensity of modern mining, the depth attained geologically is insignificant; we theorize concerning the interior of the earth while ourselves on the outside, we are compelled to infer from imperfect data, so that those who are unwilling to advance slowly from point to point have confused the subject by a mass of unsupported hypotheses. The scientific man ignores most of it, he is unaware of a great deal of it, but the average engineer or operator engaged in mining encounters the undigested ideas of pseudo-science at every turn, in his daily paper, in the prospectus, in the stope. On the other hand the geologist himself, especially in England, where economic geology was long held to be tainted by commercialism, is responsible for the unsatisfactory treatment of a subject that is as interesting as it

is important. Geologists who were keen stratigraphers and physiographers have undertaken to discuss ore deposits without going underground in mines. To go there is to soil one's clothes and to submit to physical discomfort; to those unfamiliar with them the conditions are unfavorable to accurate observation. In consequence, we have had theories that were constructed out of the smoke of the scholar's pipe and we have been taught geology that was like the kingdom of heaven, which came not by observation. The science of ore deposits has suffered inevitably. Between the theorist who does not observe at first hand and the operator in contact with actualities who does not know how to reason logically, the accepted explanations of the manner in which orebodies were formed has swung from one extreme to another, from side to side, from the purely plutonic to the wholly aqueous, either giving all the credit to ascending or imputing the whole result to descending solutions, until the man that exploits the orebody had about decided that his chance of finding ore and his ability to extract it were not likely to be augmented by much thinking concerning the origin of such concentrations of mineral. The situation was saved by the mining engineer, who became a connecting link between the man in the daily contact with facts and the professor in constant touch with books. The facts and the books came together.

Of course, the big work of comprehensive study was still done, and is being done, by geologists specially trained for the purpose; the engineer became a hodge-carrier in the new house of science, bringing the bricks of ascertained fact to the philosopher, who laid them down in ordered sequence, so that a safe structure arose out of a disordered array of building material. The simile can be carried further, but we forbear. In America the organization of the Survey brought into existence a scientific corps the first purpose of which was to apply geology to the exploitation of mineral deposits and the chiefs of that organization themselves combined the qualities of the scientific student and the investigating engineer. To the aid of accurate topographical maps they added skill in the sifting of data, many, if not most, of which they obtained from mine managers and consulting engineers. Sometimes the acknowledgement was scanty, but in the main it was generously recorded. It is true that Mr. John A. Church once spoke of "the usual self-sufficiency of the officers of the United States Geological Survey," and it is a fact that in scientific controversies between engineers and officers of the Survey, the latter have been in the pulpit, as it were, so that the layman has been at a disadvantage, but even in this regard we mention the matter merely as a stage of development that is past. In the end the mining engineer became the willing scout for the scientific authority to whom he gave all his recorded observations, and in most cases the official geologist showed such appreciation that the co-operation was more than repaid. Nowhere in civilized countries are the mining engineers and the officers of the Government Survey on such pleasant terms as in America. Thus, the mining engineer has been an important factor in forwarding the study of ore de-

posits; if that study has become of immediate practical value to the miner it is largely because the mining engineer has collected a large mass of observations in the course of his daily work. These he has given to his more scientific comrade so that by the sifting and arranging of them the true teaching of facts might be formulated into a connected theory. And this explanation of progress in America is confirmed by a glance across the water, where the stratigraphical geologist and paleontologist is a scientist in high standing while the mining engineer is still regarded as something akin to an explorer or adventurer, a distant relative of the civil engineer and only respectable in spots, certainly the inferior of the army, navy, and reserve forces, not to mention the clergy and the people that do nothing, gracefully. The geologist is held to be loftily scientific, the mining man is basely commercial; they do not meet on the same plane; there is a social unconformity. Therefore the economic geology that is purely English is insignificant, and the study of ore deposits owes so little to the official English geologists that the sum of their contributions would scarcely be missed. What there is of it is painfully academic and as far from the actualities of mining as its authors have been aloof from observation underground. But here we trespass unduly on the courtesy of some of our readers, to whose knowledge of affairs, British and Colonial, we are willing to appeal. If we emphasize this side of the subject it is to urge the members of our profession to co-operate loyally with the men that make a special study of ore deposits, to the end that all the facts available may be gathered and placed in good hands. A vast number of useful observations are being made in the drift and in the stope every day; much of it is never recorded and soon forgotten. If every mining engineer did a little by way of contributing facts and notes, the mass of available information would be enormously increased. Some may be able to collect sufficient data for an article or treatise, but the majority have not the time or faculty for such work. But even the most busy or the least literary can put his notes together and send them either to the nearest specialist or to a technical journal. We are glad to record such notes. On another page will be found an address delivered by Mr. Horace V. Winchell, a mining geologist trained in a severe post-graduate school—that of mine litigation at Butte. We intend to discuss his suggestive remarks in our next issue, and at the same time we shall refer to the scholarly contribution made recently by Mr. George J. Bancroft to the Transactions of the American Institute of Mining Engineers. This mining engineer has obtained his training in the course of examining mines for commercial purposes; it is a training that emphasizes the utilitarian value of geology.

Ruskin was a rhapsodist and in his geological studies he disclaimed deposits of mineral, nevertheless he said a thing that is strictly germane to this matter: "There is but one thing worth saying, and that is what we have seen for ourselves." Let this be the motto of the mining engineer in geological discussion; it is the bedrock on which lies the gold of true theory.

Personal.

C. W. MERRILL is in San Francisco.

AUGUSTE MATHEZ is here from Denver.

H. VINCENT WALLACE is here from Nogales.

WILLIAM L. COBB is examining mines in Utah.

P. G. LIDNER has returned to New York from Bolivia.

E. N. VAN CORTLANDT is examining mines at Bingham.

COURTENAY DE KALB has returned from New York to Los Angeles.

CHARLES JANIN is examining mines in Routt county, Colorado.

JOHN A. REID is examining mines in Mariposa county, California.

F. J. H. MERRILL will arrive here from Sonora, Mexico, next week.

T. BRUCE MARRIOTT has returned to London from Buenos Ayres.

D. W. BRUNTON has returned to Denver from a journey around the world.

E. L. WHITE, of Denver, has been doing professional work at Leadville.

F. H. MORLEY, of Denver, has been making examinations near Bisbee, Arizona.

E. M. ROGERS has left New York to inspect mines in Idaho and Colorado.

S. F. SHAW is examining mines in the Ocampo district, of Chihuahua, Mexico.

MARK L. REQUA is examining manganese deposits in Colusa county, California.

FRANK H. PROBERT is in Scotland. He will return to Los Angeles in September.

CHARLES A. GREEN, of Mill City, Nevada, is in San Francisco to buy machinery.

JOHN M. NICOL has gone to Nicaragua, in the interest of the Joshua Hendy Iron Works.

FRANK W. OLDFIELD has gone to Los Angeles, on his way to mines in San Bernardino county.

JAS. C. H. FERGUSON, Pacific Coast representative of the Midvale Steel Co., has gone to Philadelphia.

W. C. BRACE, of Denver, was here on his way to the Daulton mine, in Madera county, California.

WALTER S. BROWN is at El Tiro, in Arizona. His partnership with E. S. Wiard has been dissolved.

R. W. MACFARLANE, manager for the Cherokee Goldfields, Ltd., is in England on a visit from Mexico.

FRANKLIN R. CARPENTER, of Denver, has gone on professional work to Newfoundland and Nova Scotia.

W. A. ALLEN is now superintendent of construction for the American Smelting & Refining Co. at Salt Lake City.

E. S. WIARD has returned to Denver from Mexico. The firm of Wiard & Brown has been dissolved by mutual consent.

FRANK G. WILLIS, of Hills & Willis, Cripple Creek, is spending a few weeks in Gunnison county on professional business.

B. A. BOSQUI, metallurgist with the Great Boulder Perseverance Mining Co., Kalgoorlie, has returned to San Francisco.

WALTER G. PERKINS remains at Ely. His resignation was not accepted by the Steptoe Valley Smelting & Mining Company.

ANGUS SUTHERLAND, formerly at Idaho Springs, Colo., has become superintendent at the Boston Consolidated mines at Bingham, Utah.

THE State Legislature has appropriated for the MICHIGAN COLLEGE OF MINES, at Houghton, \$43,000 for a new central heating and power plant, also \$75,000 for a library and museum building.

General Mining News.

ALASKA.

Another tunnel project is being considered for Silver Bow basin. The Alaska-Penn. M. Co. has recently secured control of the Rae group, where a tunnel is planned for a depth of 1,200 ft. to connect with the apex of the lode by a 1,000-ft. raise. A compressor will be installed and the tunnel driven by contract. This mineral belt includes the Ebner, Hallum, Alaska-Juneau, Perseverance, Alaska-Penn., and other properties.

ARIZONA.

COCHISE COUNTY.

Four furnaces ran continuously during June, at the Calumet & Arizona smelter, and the output was about 4,000,000 lb. copper. The new machine-shops are completed, and

will be increased to 3,500,000 lb. copper. Men are grading for a new dust-chamber and stack, to be completed before the sixth furnace is installed.—The Arizona Commercial company is again shipping 200 tons per day from the Copper Hill mine, while at the Black Hawk mine a sump is being cut at the 500-ft. level.—The Great Eastern shaft of the Superior & Boston is down 220 ft., the Limestone shaft is 130 ft. deep, and the winze 35 ft.—The Inspiration company has received returns from 15 tons of concentrate shipped to the Old Dominion smelter, the consignment netting \$1,863. J. D. Coplen is the manager.—Shipments of 80 tons are coming daily to the Old Dominion from the Gibson mine. Ore running 25% is being mined in the Pasquale tunnel.

PINAL COUNTY.

The Newbury company has purchased three 100-h.p. boilers, with engines and dynamos, for an electric power-plant to be built on the Gila river, 16 miles east of Florence, near the old Butte smelter site. A 19-drill compressor has been ordered and an electric pump and hoist will be installed at the Newbury mines. An aerial tram will be built from the mines to the railroad, where ore-bins will be constructed. C. M. Schofield is the superintendent.

The old Vekol mine, 30 miles south of Casa Grande, is to be worked again by a new company incorporated by S. J. and E. S. Garrett, and W. H. Forebach. They are also operating the Copperosity property, which lies in the same limestone belt.

YAVAPAI COUNTY.

The Dillon tunnel of the Hull Copper Co. is in over 2,000 ft., and as soon as connection is made with the 1,888 shaft, cross-cutting will be started at several points in the tunnel. This shaft is 450 ft. deep, and there is a drift from the 450-ft. station, but the workings are full of water to within 150 ft. of the surface.

CALIFORNIA.

AMADOR COUNTY.

The Sutter Creek Gold Co., operating about eight miles south of Sutter Creek, has started up the new concentrators. A cross-cut is being run from the 200-ft. level. Sidney Drake is the manager and Jack Hall the superintendent.

BUTTE COUNTY.

It is reported that the Butte Star mine has been sold by E. C. Wilson and others, to Pennsylvania capitalists. A good deal of interest is being taken in the deep river channels along the Magalia ridge. The Mammoth Channel G. M. Co. is preparing for development work, and the rich channel has been struck on the J. B. Steifer Mining Co.'s ground.

EL DORADO COUNTY.

Work continues steadily at the Beattie, Pacific, Golden State, Magnolia, Crane's Gulch, and Gold Bug mines near Georgetown, but no strikes of unusual importance have been reported.—The cross-cut in the Neptune should cut the vein in a few feet.—The mill at the Vivian mine is nearly finished and the machinery is being put in place.—At the Alpine mine, work has stopped, pending the expiration of the Wingfield option, but the pumps are running continuously and the mine is free from water.—A good dump of pay-dirt has been accumulated at the Cooley mine by Brazil Gigax & Co., and the sluices are nearly completed.—A carload of machinery from the Walker mine in Old Diggings, Shasta county, has been shipped to Georgetown and will be installed at the Idlewild, or Taylor mine, by the Thompson Brothers, who have a lease on the property. The mine will be unwatered to the 200-ft. level, from which point work will proceed north of the shaft.—Fountain & Buchler have found good gravel in the main tunnel of the Trimble mine.

The Round-Out mine, in the Blairs district, owned by Richards & Fairchilds, has been sold to the Nevada men who are operating the Pilot Knob mine. Grant S. Estey is in charge. About 200 ft. of tunnel will be driven before gravel is reached.—W. I. Smart is moving the machinery and buildings from the Delwisch mine to the Gravel Hill property. More men will be put on as soon as the mill is completed.

Southeastern Arizona.

the structural-steel framework for the new power-house is nearly all in place. This new power-house will be double the size of the old one. A new 500-ton furnace has been planned and material for it has already arrived. Each of the four old furnaces will be increased in size from 300 to 500 tons daily capacity, making 3,000 tons daily capacity for the plant.

GILA COUNTY.

Much work has been done in the Old Dominion during the past month. No. 3 sulphide vein has not yet been reached by any of the cross-cuts on the fourteenth level, but it has on the thirteenth and was found to carry good ore. A drift being run west on No. 3 vein, thirteenth level, has been in 20% copper ore for some distance, the orebody averaging 10 ft. wide. The double-compartment winze is sunk 50 ft. below the fourteenth level. The new furnace will be blown in this week, and the monthly production

MONO COUNTY.

A road is being built from Calavada to the True Friend property. The gasoline hoist for this property is at Minden, and will soon be erected.—About 20 men are doing development work on the Pittsburg-Liberty claim. Weltfle & Eastwood have let a contract to Foley & Morgan, to sink a shaft on their lease on the Pittsburg-Liberty.

NEVADA COUNTY.

Operations will be resumed at once on the Birchville mine, near Graniteville. The pumping plant will be enlarged and the incline shaft, now down 400 ft., will be sunk deeper. Fred Medlin is in charge of the work.—The North Star Mines Co. has just paid a dividend of 20c. per share, amounting to \$50,000. The quarterly statement of the affairs of the company has just been issued.—L. C. Heler, who is developing a vein of antimony ore on the Johnson ranch, south of Grass Valley, reports encouraging showings.—A blind vein has been uncovered in the Marcotte, near the Ethel mine.—A strike has been made in the Mountain View, near Washington, and good progress is being made on the Arctic.—E. E. House will have charge of the Morning Star mine at Badger Hill, near Patterson, in the Cherokee district.

The Golden State M. & D. Co. has been incorporated to work the Ozall & Shelby mine in the Chicago Park district. A 10-stamp mill will be installed. Three tunnels have been run to prospect the ground.—Driving continues on the 1,400-ft. level of the Canada Hill mine, and a station will be cut on the 1,500-ft. level.—On account of the State law which imposes a license tax upon all corporations, 11 mining companies in this county have reduced their capital stock. The law graduates the tax according to the amount of capital stock, so large capitalization will probably not be as popular as heretofore.

The Oustamah mine on West hill has been sold to E. A. and J. O. Hayes of San Jose, who were represented in the deal by Frank B. Everett. The hoisting and pumping plants will be enlarged and the incline shaft that is down 900 ft. will be sunk and the property thoroughly developed. There is a 10-stamp mill on the Oustamah and a 3-stamp mill on the Eddy, which goes with the other property. The Oustamah, which is only one-half mile west of Nevada City, has been owned by the Morgan family. It was operated in the sixties and was formerly known as the Pennsylvania.

SAN BERNARDINO COUNTY.

The Orange Blossom M. & M. Co. will erect a stamp-mill upon its property, 10 miles north of Bagdad. Water will be pumped from Budweiser springs. The mill will be equipped with Nissen stamps, will have a capacity of 50 tons per day, and will be in operation by October 1.—H. M. Glidden, of Spokane, has taken an option on a group of 10 claims on the Mohave desert near Amboy, and \$35,000 has been paid, to apply on the purchase price.

SHASTA COUNTY.

(Special Correspondence).—The iron smelter erected to treat the high-grade iron ores near Baird by the Heroult electric process is completed. The preliminary heating of the furnace for drying the lining is finished, and arrangements are being made to commence smelting this week. The railroad is being graded within a mile of the smelter, and it is expected that communication with the Southern Pacific will be completed in a few months.—A discovery of rich copper ore within a few feet of the surface, west of Shasta, has recently attracted considerable attention. This find, being made beyond the southern extremity of the known copper belt, is encouraging prospectors to develop the shear-zones in the district, which carry small quantities of copper, which may prove amenable to concentration.—At the Yankee John mine, near Centerville, rich ore has been struck at the 75-ft. level. Specimen rock assaying about \$5,000 per ton is being shipped. The workings are now below the oxidized zone, and the prospects in depth are excellent. The shaft is the deepest in the district, and sinking will be continued. The ore occurs in a number of

veins with quartz and calcite. The country rock is slate with andesite intrusions.

Redding, July 1.

The new electric hoist at the Gold Leaf mine, near Shasta, is in operation and the raise from the tunnel to the surface, 120 ft., has been finished. H. O. Cummins is the manager.—A new gasoline hoist has been installed in the Gambrinus mine, near Whiskeytown, at the end of a 500-ft. tunnel, where it will hoist from the winze.—The furnace of the Great Western Gold Co.'s smelter at Ingot has been blown in, after a short shut-down. J. S. Henderson is the president and S. E. Bretherton the manager.—J. C. Rhodes has resigned the superintendency of the Donkey mine.

SISKIYOU COUNTY.

George Kradle is superintendent of the Blue Nose mine.—A fine body of ore has been opened in the west drift of the Russell, Sheffield, & Callahan mine.—The Sisson E. & M. Co. will develop the Home group of mines, two miles west of Sisson. Fred Zimmerman is in charge.—The Morrison-Carllock shaft has been repaired and a full crew is again at work.—John Quigley has completed 900 ft. of work in his tunnel on Indian creek.—Noel E. Graves, superintendent of the Sheba mine, reports that he will have the mill going within a week.—John O. Harrison has got an extension for one year of his option on the Race Track placer property, which is a continuation of the Blue Gravel mine, one mile south of Yreka.—The French company, which operated on South Fork and Wildcat creeks, has resumed operations, and the giants will be started under the direction of Fred Beaudry.—At a recent meeting of the directors of the Headwaters G. M. & M. Co., in New York, it was decided to continue the development of its property on Humbug creek. John E. McBride is the managing director.—The first load of machinery for the new link-belt dredge for Callahan has arrived, and the old dredge is being dismantled. The power-house of the company is being changed from a direct to an alternating-current system.

The new steam scraper used by the Los Angeles Co., on Klamath river below the Quigley ranch, is working satisfactorily.—The construction of the California-Northeastern railroad from Weed, through the mountains between Grass lake and Butte creek will open some good country to prospectors.—The Nordheimer mine on the Salmon river has been sold to Palo Alto and Los Angeles parties. This property has been a producer for 20 years. The same people have purchased the Markusen mine, which will be in charge of J. L. Fehely.—A good many men are at work on prospects near Happy Camp.—The Dick Johnston quartz mine will be operated by G. W. Addison.—The Blue Nose mine has been closed, but work will be resumed in September, when a cyanide mill will be built.—J. M. Morrison, formerly one of the owners of the Morrison-Carllock mine in Quartz valley, has bought the Snook & Burns property of 160 acres, in Plowman valley, and will develop it.—The Blue Gravel lease which has been in existence for 15 years, has expired, but the ground will probably be taken over by a new company.—L. C. Trent is working 15 men in the cross-cut at Mineland.—J. L. Welker is working the Lehigh claim in Volcano canyon. This is a tailing-claim that has been fed for years by the gravel from the Paragon.—Rich gravel has been struck in the McGeachem mine east of Iowa Hill. This ground adjoins the Jupiter, and Elmer Rose is the manager.—Some good ore has been taken out of the Louise vein by Dugald Duncan.—A number of arrastres will be put in at the Clipper property this summer. This mine is an extension of the Wise vein on the north fork of the American river.—At the Hidden Treasure, 45 men are working. The tunnel has been driven for 1,200 ft. through the reef of rock about 8,000 ft. of old river-bed remains to be worked.

H. R. Patterson has taken over the Spencer quartz mine on Humbug creek. It is estimated that there is ore worth about \$50,000 on the dumps, and this will be cyanided. Work will commence at once.—S. V. Davidor, who bought the McKinley mine, on Humbug creek, has incorporated the property under the name of the Champion

Group M. Co.—The water supply is becoming very low among the camps of this county.

TRINITY COUNTY.

The Keating group of claims, on Hardscrabble creek, has been bonded to Oakland parties for \$40,000.—The giants at the Union Hill mine have sluiced off the overburden and struck some rich gravel-pockets in the banks. No clean-up has been made, and hydraulicking is carried on continuously, as the water supply is running a little short. About 15 men are employed at the property.

One plant is running continuously at the Union Hill mine, near Douglas City. The Sugar Loaf hill gravel, and that in the lower mine, are being sluiced. The supply of water is decreasing, and will only last one more month, but a new reservoir will soon be completed, which will give more storage room for next season. C. E. Goodyear is the superintendent and H. E. Crowell the manager, and 18 men are employed.—A covered tramway is being built at the Bullychoop mine, to prevent snow from interfering with the mill-supply during the winter. About 50 men are employed and 20 stamps are dropping.

TUOLUMNE COUNTY.

T. H. Bluett and J. A. Gillis have finished unwatering the Kapp & Jardine shaft on Jackass hill, near Tuttletown. A suction ventilator is in operation and they are sinking the shaft from the 225-ft. point.

A number of mining men at Groveland have organized the Southern Tuolumne Miners Association with A. P. Dron, president, and H. S. Richardson, secretary-treasurer. Mine owners, operators, and managers are eligible to membership and over 30 men are charter members.—A cross-cut has been started at the 100-ft. level of the Lion mine.—The Imperial Gold Mining Co., operating on Kanaka creek, will begin erecting a 10-stamp mill about August first.

COLORADO.

TELLER COUNTY.

(Special Correspondence).—The Gold Sovereign has recently encountered a four-foot vein of 12 oz. silver and 6 oz. gold ore in the 1,200-ft. level and is shipping regularly. Some ore is being broken in the No. 3 shaft that averages 6 to 8 oz. mill run. They recently opened a good-sized shoot north of the main shaft that had never been opened before. A portion of the property is under lease. Abram Rapp is the manager.—Adjoining the Gold Sovereign on the western slope of Bull hill is the property of the Trilby Mines Co., for which James T. Stewart is manager. The shaft on this property is down 860 ft. and it is producing about 50 tons of shipping ore per day which runs from \$25 to \$50 per ton. The property is equipped with an Ottumwa Iron Works hoist and eight-drill compressor made by the Chicago Pneumatic Tool Co. L. K. Mearkle, of Pittsburg, is the president.—The Vindicator Con. Gold M. Co. is shipping about 2,000 tons per month from both the Vindicator and the Hull City placer, which is now under the control of the Vindicator company. The company owns about 40 acres. Exhaustive tests were made some time ago which seemed to be satisfactory, but before concentrating for a mill to handle the low-grade material and dumps of the mine they have decided to make more tests, and as a consequence F. J. Nagel, recently with the New York & Honduras Rosario Mining Co. is putting the plant in the old Lillie shaft-house in shape to make the tests for the company. If these tests are satisfactory it is expected a larger plant will be erected. The shipping ore is put through three different washers, and as a consequence about five cars of \$60 ore is saved per month. The Vindicator shaft is down 1,200 ft. and the Hull City shaft 1,262 ft. It is understood the drainage tunnel which is being driven will drain their ground to the 2,100-ft. level. F. J. Campbell is general manager.

Cripple Creek, June 22.

NEVADA.

CHURCHILL COUNTY.

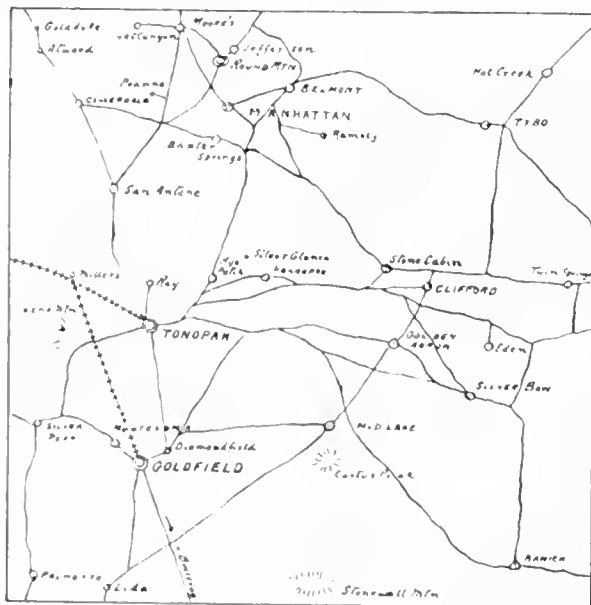

(Special Correspondence).—The Spider-Wasp company is sinking a double-compartment shaft. The new hoist is

expected to arrive soon. A little good ore is blocked out. Two of the lessees are working in ore, and the others are in promising ground. A bunkhouse and blacksmith shop have been erected.—At the Wonder-Central the vein is showing up well, and development is under way.—A strike has been made in the tunnel of the Nevada-Wonder, some of the ore assaying \$324 per ton. Gold predominates, and the vein is several feet wide. Over 300 sacks have been filled with ore since the last shipment.—The Nevada Dixie G. M. Co. has secured a group of claims in Dixie valley, 35 miles north of Wonder. In places the vein is 25 ft. wide. The rich strikes in Dixie have caused a rush from this camp.

Wonder, June 27.

ESMERALDA COUNTY.

(Special Correspondence).—The Nevada-Goldfield Reduction Works treated 1,511 tons of ore last week from the following properties: Little Florence, 368 tons; Mohawk-Combination, 294; Ish-Sheets lease, 192; Reitz, 129; Mohawk-Jumbo lease, 118; McNaughton lease, 92; Con-

Part of Nevada.

solidated, 90; Loftus & Davis lease, 66; Red Top, 64; Codd lease, St. Ives, 42; Combination Fraction, 40; and Higginson lease, 16 tons. This does not include the ore handled at the Combination mill or the railroad shipments. The total production was approximately 3,200 tons.—A rich strike has been made in the 100-ft. level in the Florence. The vein is four feet wide.—The shaft on the Higginson lease is being sunk 50 ft. deeper. The vein at the 230-ft. level is three feet wide and runs well. The lease is on the Wedge claim of the Jumbo Extension.—The Kalfus and Ish-Sheets leases have been consolidated. The Kalfus lease is on the Mohawk, the Ish-Sheets on the Combination. Most of the work will be done through the incline shaft on the Ish-Sheets. The lease runs six months.—The Consolidated Mines Co. has secured a one-fourth interest in the Vinegarone claim, lying between the Red Top and Laguna.—The shaft at the Red Top Fraction is down 190 ft., and will be put down to 300 ft. A good strike has been made in the 172-ft. level, some ore running \$200 per ton. A station will be cut at the 200-ft. level and cross-cuts driven.—The Curtis lease on the Jumbo Extension has passed into the hands of the Frances-Mohawk company for \$50,000. A rich strike has been made on the 315-ft. level. D. McKenzie is directing operations.—Good ore has been encountered on the 218 and 250-ft. levels in the Mohawk-Florence.—The Gold Bar shaft is down 260 ft., and much development is under way. Two leases are operating.—The Golden Crown L. Co. on the Silver Pick has the shaft down 175 ft. At the 140-ft. level a small shoot of ore was found.—The Frances Mohawk Co. has struck a rich lode of sulphide ore on the Wedge, a fractional claim adjoining the Mohawk.

Goldfield, July 5.

HUMBOLDT COUNTY.

(Special Correspondence).—Rosebud is growing rapidly, and daily trips are made by stage to Winnemucca, Mill City, and Humboldt. Miners are receiving \$4, \$4.50, and \$5 per eight-hour shift. Lumber is selling for \$90 per thousand feet.—At the Brown Palace, ore is being taken from the bottom of the 70-ft. shaft, and is sacked for shipment. Two cross-cut tunnels are being driven to cut two veins, and some good ore has been encountered. Alline Case is the superintendent.—Two shafts and a 325-ft. tunnel on the Golden Anchor have exposed good ore, and a drift and cross-cut are being driven to open up the vein. Silver predominates in the ore.—At the White Alps, a four-foot vein has been struck in the cross-cut from the 50-ft. shaft. In the tunnel that is being driven northeast of the shaft, ore running over \$100 per ton has been found.—At the Big Six, ore running \$122 per ton in silver and gold is being extracted.—In the Durango Girl, development is steadily progressing. The vein is of fair size, and has been traced over 2,000 ft.—Sinking has been resumed at the Dreamland, and the shaft will be put down to the 200-ft. level. A large vein running \$25 per ton lies in the bottom of the shaft. Promising ore has been found in the drift.—The Rosebud M. & L. Co. has secured leases on the Brown Palace and White Alps, and is putting a large force of men to work. A royalty of 25% will be paid the owners on ore running \$50 and over. The Rosebud Central M. Co. has secured five claims at this point, and is preparing to put men to developing its holdings.—Development work is under way on the claims held by the Nevada Rosebud Con. M. Co., and a tunnel is being driven on a promising vein. The claims are near the Brown Palace, Golden Anchor, and White Alps.—Excellent ore has been found on the Look-out claim of the Rosebud-Rattler M. Co. The vein is several feet wide, with some ore running \$40 per ton.

Rosebud, June 26.

NYE COUNTY.

(Special Correspondence).—A contract has been let for the construction of a 10-stamp mill for the Gold Bar Co. Grading for the site has commenced and the pipe-line from Mud Springs is being laid. The shaft is down 460 ft. and will go down to 1,000 ft. A station has been cut at the 450-ft. level.—The \$300,000 plant at the Montgomery-Shoshone is being rapidly constructed by the Traylor Engineering Co. Developments at the mine are progressing, and ore is being blocked out.—Another rich orebody has been discovered in the north cross-cut on the West Extension. The vein is of fair size and contains free gold. The strike is one of the richest yet made in the mine.—The Lost Burro group has been bonded by Julius Lemle and associates of Beatty for \$45,000. A force of men is at work.—The Ubehebe M. & S. Co. announces its intention to erect a smelter at Ubehebe at an early date. It is planning to construct a railroad from the camp to Thorps Well on the Goldfield-Bullfrog road. The company owns 50 claims in the Ubehebe district.—An English company is negotiating for the Homestake-King property. The mine is being sampled.

Bullfrog, July 3.

(Special Correspondence).—The shaft on the Great Western is down 150 ft. Two veins have been traced several hundred feet. Assays of \$12 per ton have been secured.—On the April Fool, some ore has been found, but the development has not been extensive.—Excellent ore has been found in the Lime Point, which was recently acquired by the Ish brothers.—At the Bonnie Claire recent developments have opened up a vein, and some high-grade quartz is being extracted.—Developments at the Wyman-Vyek are proving the property a valuable one. The shaft is being sunk.—The second power-line of the Nevada-California Co. insures the operation of local properties throughout the year. The first line was inadequate for this purpose.

Lida, July 2.

WASHINGTON.

CHELAN COUNTY.

(Special Correspondence).—E. J. Forman, of Seattle, has taken a bond from Kingman & Pershall for \$20,000 on the claims on Chelan butte, paying \$2,000 down, the balance to

be paid in installments, and the vendors to reserve 1,600 lb. of ore already sacked, and valued at \$1.25 per pound. The claims have not been developed over 13 ft. in depth.

Republic, July 5.

FERRY COUNTY.

(Special Correspondence).—The question of finding copper of economic value on Belcher Mtn., about 12 miles northeasterly from Republic, is one of interest to the mining men of this district. From the Copper Key mine, about 40 ft. below the surface, nearly 3,000 tons of iron oxide ore were stoped and shipped to the smelter. The stope is 90 ft. long, 45 ft. wide at the north end and 23 ft. wide at the south end. The ore contained no copper, but paid a profit out of the gold contents and excess of iron. The course of the stope was north and south. A winze was sunk 60 ft., and the trend of the vein became a matter of doubt. A cross-cut adit, known as the No. 2, was driven, but no ore was found on that level where it was expected. A survey was made, and a raise was run 40 ft., leaning slightly southward, and connected with the incline. From the top of the raise a cross-cut was driven 40 ft. in a southerly direction through a mass of iron oxide and sulphide, which pitches southeasterly and strikes northeast-southwest, a decided change from the course of the deposit in the upper workings. The ore extracted in cross-cutting assays 0.5% copper and \$6.19 gold per ton. From the No. 2 adit a cross-cut was driven southerly 43 ft. to the foot-wall and thence 31 ft. across a body of iron sulphide and magnetite, but not far enough to strike the hanging wall. In the lower cross-cut a stratum of somewhat silicious ore, 2½ ft. wide, was encountered, which assayed 2½% copper, and samples from the ore on either side showed some gold and silver. On this level the depth on the pitch of the vein is 245 ft. and the vertical depth about 200 ft. It is probable that exploration will be resumed from the No. 3 adit, the deepest opening in the mine, with a view to connecting with the orebodies above.—The Colville M. & S. Co. has traced the cropping of a silver-lead vein on the North Half group 350 ft. and driven an open-cut 20 ft. across a vertical vein of galena and carbonate of lead.—The Bortle Copper-Gold Co. has driven from its main working shaft 104 ft. north, into the ground of the Belcher Mining Co., at a depth of 60 ft. Another drift has been started in the opposite direction.—The British Columbia Copper Co., since it bonded the Lone Star and Washington claims in this county, has opened about 1,200 ft. of drifts, cross-cuts, and raises in 10 months. The work was started by cross-cutting the vein with an adit and afterward driving and raising on it. Bunches of ore assayed as high as \$50 per ton, but the ore ordinarily assays from \$15 to \$25 per ton in copper and gold, the former having the most value. The vein, which is rather flat, is from 40 to 70 ft. wide. The raises of 50, 80, and 100 ft. respectively, are in shipping ore, and the mine is developing so well that the company has decided to take up the bond. The ore goes to the company's smelter, at Greenwood, B. C.—The Amalgamated Republic Mines Co. has been incorporated under the laws of Arizona, to operate and purchase under bond and lease the Republic, Pearl Consolidated, Quilp, North San Poil, Trade Dollar, Midget, and Ben Hur mines, in Republic. The capital stock is \$2,000,000, of a par value of \$5 each. This company has taken over the options secured last February by Harry L. Rogers and negotiated for the purchase of the dismantled mill buildings of the Republic Power & Cyaniding Co. It is announced that J. C. Beidelman, the inventor of the new process for treating the ores of Republic camp, will have the management of the mines and mill, and that special machinery has been ordered. It is expected to treat the ores of the camp for \$2 to \$3 per ton. The articles of incorporation were to be filed by the company with the Washington Secretary of State, who is reported by the newspapers as having refused to file them, on the ground that one object of the company is to buy real estate in Washington, which is not legally permissible for a foreign company in this State. Lawyers are of opinion that a company organized under the laws of any State in the Union is not a foreign corporation within the meaning of the Act passed upon by the Secretary of State.

Republic, July 3.

STEVENS COUNTY.

(Special Correspondence).—G. H. Walters, Frank P. Milcark, and J. A. Maicell, of Spokane, have incorporated the Viking Copper Co., to develop a group of three claims in the Pierre Lake district. The property is half a mile from the railroad, and shipments will soon begin, the company having been guaranteed a freight and treatment rate of \$3.50 per ton.—An eight-foot vein of ore has been discovered at the surface on the Nellie S. mine, near Chewelah. The ore from the bottom of a 15-ft. prospect shaft assays \$34 per ton. It occurs in a contact between granite and lime. The mine is owned by Fred R. Clark and Phillip N. Clark, of Spokane, and is being developed under the direction of Conrad Wolfe, president of the United Copper Mining Co. The vein found by Mr. Wolfe is 200 ft. west of the main shaft, which has been sunk to the 200-ft. level on a four-foot vein. A cross-cut will run from the bottom of the 200-ft. shaft to get the west vein. It is thought, on account of the decided dip of the vein, that 125 ft. of cross-cutting will reach it. Machine-drills are installed at the property. Ore is being shipped from the 100-ft. level.—The suit of the Roselle Mining Co. of Spokane, against the Krupp Fire Arms Co. of Germany, to recover title to the mining property in Stevens county, was decided by Judge E. H. Sullivan in favor of the plaintiffs. The suit has been pending several months at Colville, and the property involved is valued at several hundred thousand dollars. It is situated in Cedar canyon and contains deposits of tungsten. The Roselle company is a close corporation, the stock of which is owned largely by Spokane people. The Krupp interests took possession of the property after it had been patented by the Roselle company, their claim being that they had purchased it from a former owner.—W. L. Wakely, of Spokane, has found several pockets of molybdenum in the northeastern part of Stevens county, where development work will be pushed.—Probably the richest strike of ore in the Metalline district, north of Spokane, has just been declared on the Flussie group on the Pend d'Oreille river. It carries lead, gold, and silver, a picked sample showing 74% lead, \$92 gold, and an ounce of silver. The vein is 50 in. wide and 90 ft. long. S. H. Anschell, one of the owners of the group, says that extensive work is being done at the Mammoth, Morning, Flussie, Diamond R., Bella May, Blue Bucket, Lead King, the Clark group of 41 claims on Flume creek, and the 54 claims of the Sterling Silver-Lead company.—The property has been opened to a depth of 100 ft. The mine was located in September, 1905, and covers 255 acres. The Sterling Silver-Lead company is building a four-mile flume and has erected a sawmill to cut the lumber.—The Spokane Lead Mines Co., operating the Bella May and the Diamond R., is building a 100-ton concentrator which will probably be ready next fall. Lack of transportation facilities is the drawback to the district now, but a line will be built before long. There is ore awaiting transportation.

Spokane, June 29.

(Special Correspondence).—The vein discovered 200 ft. west of the main working shaft of the Nellie S. mine has been unexpectedly encountered in a cross-cut from the bottom of the shaft at a distance of 35 ft.—The last carload of ore from the Jay Gould mine, near Chewelah, netted approximately \$32 per ton. It came from the 180-ft. level.—An adit drift on the Lucky Bill mine is in 250 ft., and the vein averages 30 in. wide. A contract has been let to drive it 100 ft. farther. There is some native copper in the ore.—The United Copper Co., after cross-cutting the vein by an adit at 600 ft. from the portal, drove a drift 50 ft. on the vein and then cross-cut it. The vein is 40 ft. wide and 95 ft. deep at that point and has 18 ft. of shipping ore on the foot-wall. On the 350-ft. level the ore is low-grade across 25 ft., but higher grade material is expected on the hanging wall.

Republic, July 5.

BRITISH COLUMBIA.

At Rossland, the big compressor of the Centre Star mines is being repaired and the Nickel Plate and War Eagle plants are furnishing compressed air. The vein on the Idaho is still being stripped. The War Eagle is looking good from

the fifth to the eleventh levels. Development is in progress on the 350, 400, and 450-ft. levels of the Iron Mask.—At Le Roi No. 2, the unwatering of No. 1 continues, but development has not started on the Surprise and You Know, as it is difficult to get men.—The White Bear hoist is being repaired and no ore or waste is being hoisted.—J. A. Miller has been appointed superintendent of the California-Giant properties.—Alex Robinson has started a few men to work on the Golconda group in South Deadwood.—A big slab of pyrrhotite, containing free gold, has been taken out of the War Eagle mine, and has attracted a good deal of attention, as free gold is rare in this camp.—Hoisting machinery has been ordered for the New Wellington coal mine. Two shifts are mining coal of excellent quality.—The Reward Mining Co. of St. Paul, owning 22 claims on the south fork of the Lardeau river, has let a contract for 500 ft. more of work. The tunnel is in 1,300 ft. and will cut

Map of Part of British Columbia.

two veins that are exposed on the surface.—J. P. Graves states that the Granby smelter will again be enlarged to a capacity of 4,500 tons per day, making about 40,000,000 lb. of copper per year.—The third furnace at the Boundary Falls smelter of the Dominion Copper Co. has been blown in and will be kept running if the C. P. railroad can keep it supplied with ore.—The British Columbia Copper Co. has established a new record for seven-day's smelting, it treating 13,647 tons, derived from the following sources: Custom ore, 4,438 tons; Mother Lode, 7,026; Napoleon, 347; and Oro Dinero, 1,836 tons of ore.—The Phoenix Amalgamated Copper Co. has recently purchased the Four Aces and Keystone claims just south of the Granby group, from G. W. Rumberger and J. P. Dermody.—The new smelting record of the Dominion Copper Co.'s works is 5,566 tons in one week. This company is considering the erection of an aerial tramway from the company's mine in Phoenix to the Boundary Falls smelter, to obviate the difficulties of the constant car shortage. Maurice M. Johnson, the manager, thinks it would not be over five miles long, although the ore has to go about 25 miles by rail.—Over 1,100 men are at work in Phoenix, the Granby company employing 500, the Dominion Copper Co. 300, and the Snowshoe, 125 men.

MEXICO.

SONORA.

The Llanos company of Boludo, 45 miles from Santa Ana, has shut down the 50-stamp mill that has been crushing gravel, and will work the property by sluicing. This part of the State is showing great activity and the larger quartz mines have been amalgamated into one company through the efforts of F. B. Lloyd of San Francisco, with whom is associated Epes Randolph and Mr. Lindsey.

London.

The Dumps of Stratton's Independence.—Report of Philip Argall.—Interesting Conclusions.—Treatment of Low-Grade Ore.—Tomboy and Camp Bird Outputs.—Mexican Returns.

In fulfillment of their promise made to the stockholders in March last, the directors of Stratton's Independence, Ltd., have issued a report from the consulting engineer, Mr. Philip Argall, on his new milling and mining scheme. Dealing in the first place with the ore-house dump, estimated to contain 600,000 tons of an average value, shown by careful and conservative sampling, of \$3.60 per ton, Mr. Argall states that after an exhaustive series of tests on this ore, he came to the conclusion that although the best extraction can be made by roasting and direct cyaniding, owing to cost of roasting in the Cripple Creek district this process is not applicable on ore of such low tenor. He remarks that it is a curious fact that the raw or unroasted sulpho-telluride ores of Cripple Creek will, when reduced to a suitable degree of fineness and agitated in cyanide solution, give an extraction of 50 to 60% of their gold contents. This rule appears to hold good whether the ore contains \$1 per ton or \$20 per ton in gold. It is obvious then that if by any process of concentration the bulk of the sulpho-telluride could be separated from the gangue, the latter would, on treatment by cyanide solution, give up one-half of its residual gold, and be reduced to a fairly low tailing. Experiments on a working scale not only confirmed this, but also showed that if the crushing and concentration were conducted in dilute cyanide solution, the maximum extraction from the tailing was practically reached in one hour's contact. In the first three tests conducted on a full working scale it was found that one-third of the gold in this dump ore could be recovered as a concentrate after a preliminary crushing to pass 0.03-in. screen aperture, the exact figures being: Test No. 1, 33.33%; No. 2, 32.87%; No. 3, 33.55%; average, 33.25%. These results show clearly that a uniform recovery of one-third can be made by simple concentration. The slime produced in crushing contained practically one-third the gold of the original ore. Tabulating the separate products resulting from crushing and concentrating 100 tons of dump ore, Mr. Argall shows the following result:

4.75 tons concentrate @ \$25.263 per ton.....	\$120.00
23.00 tons slime @ 5.50 " "	126.50
72.25 tons sand @ 1.57 " "	113.50
100.00 tons dump ore @ 3.60 " "	\$360.00

He obtained a combined extraction on the dump ore of 71.22%, but bases his estimate on 70% extraction. With this extraction, a recovery of \$2.52 per ton of the average value of the dump ore is effected at an operating cost (based on treating 10,000 tons per month) of \$1.52, leaving a net profit of \$1 per ton. Mr. Argall proposes the erection in the first place of one unit only of wet-crushing plant to treat 5,000 tons per month, reserving the second unit until the millsite, chosen on the most suitable spot, can be extended by the clearing away of the dump ore that now covers the ground. The erection of the second unit, which would double the monthly profit from dump ore, should be started in about six months after the commencement of milling with the first unit.

The second feature in the new scheme is the proposed working of the low-grade ore in the mine. Mr. Argall states that it is impossible to estimate accurately the quantity of such material available. Three possible

sources of low-grade ore in the property are enumerated: First, large pillars of mineralized ground near the junction of the Independence and subsidiary veins, also several pillars left on the main veins, and bodies of low-grade ore, as for example on the sixth level where the manager believes a large tonnage of \$5 to \$7 ore can be mined. A second source of low-grade ore is to be found in old stope fillings that have sampled \$5 per ton; this ore could be drawn and sent through the mill at a possible profit of \$1.50 per ton. Third, in mining by the 'caving' system a large tonnage of low-grade ore may be obtained. Some of the big stopes are now caved, and the lessees are drawing the caves, sorting out the rich ore, and screening out the fine, thus obtaining two high-grade shipping products, and leaving the low-grade in the mine. In the lode system of Stratton's Independence many veinlets, seams, and films of rich ore extend into the vein-walls, and while they are not rich enough or numerous enough to pay in ordinary mining, it is expected that by the 'caving' system this wall-rock can be handled profitably; furthermore, it is expected that in places bunches of high-grade ore will be encountered in the hanging-wall country that would for a time materially increase the production of high-grade ore (sorted ore) as well as enrich the fine or low-grade screening. In any case, Mr. Argall is of opinion that large quantities of very low-grade material will have to be handled, and to do this in the most economical manner he recommends the erection of a special breaker plant at the mouth of the shaft. This plant should crush, screen, and wash the ore for \$1 per ton, including the cost of mining. Assuming 300 tons of caved material gave 50 tons of screening assaying \$15,

Then 50 tons of screening @ \$15.....	\$750.00
Mining 300 tons @ \$1.....	\$300.00
Milling 50 tons @ \$3.50.....	175.00
Loss in tailing	70.00
	545.00
300 tons of crude ore at a profit of 68c. per ton.....	\$205.00

It is pointed out that this estimate is necessarily based on an assumed tonnage and value of screenings; it is a process that must be put into actual work to demonstrate not only the value of the crude ore but also the tonnage and contents of the resulting screened product. Mr. Argall states, however, that the lessees are at present obtaining from their method of hand-sorting the caved material in the mine a higher average than that taken in his estimate. At the same time he thinks that one is justified in an untried scheme like this in taking only half the profit shown in a hypothetical estimate, and in that case, the breaker-plant would show a profit of \$3,000 per month, though his personal opinion is that so long as the caves follow the vein-system the breaker-plant will more nearly come up to the profits shown in the above estimate.

The third and last feature of the scheme is the production of high-grade ore. Mr. Argall reports that the lessees should produce high-grade ore in fair quantity for some time to come. High-grade ore should also be produced from the caving system of mining hereinafter described, and also from stopes on the low-grade veins, which will doubtless contain in places bunches of high-grade ore easily picked out or mined separately. All the high-grade ore will be roasted, amalgamated, and cyanided in the proposed dry-process mill, together with the concentrate produced from the wet process (concentrating) mill. For the purpose of this new scheme ores above \$10 per ton are called high-grade, and it is proposed to work them by the dry process. Ores below \$10 per ton will be treated in the proposed wet-process mill, and are classed as low-grade. Summing up the monthly net profits under the three heads of the scheme as

described by Mr. Argall the figures are: From dump ore (two units), \$10,000; from the breaker plant on low-grade mine ore, \$6,000 (or one-half of this "on the safe side"); from leases on high-grade ore, \$4,000. Thus the directors' statement that the net earnings available for dividends as from the starting of the complete mill should amount to little short of £50,000 per annum appears reasonably justified. The following is Mr. Argall's estimate of the cost of erecting and equipping the plants he advises:

Breaker plant.....	\$ 20,000
Two units of wet-crushing plant.....	190,000
Water-works for plant.....	7,500
Dry-process mill, 3,000 tons per month.....	71,000
Dump-loading plant.....	15,000
Transformer-house and wiring.....	6,500
Total.....	\$310,000

On the financial aspect of the scheme, the directors report that the Company possesses ample funds for the purpose contemplated. Inclusive of profits at the mine to the end of May, the Company's cash amounts to £48,700. In addition there are net liquid assets of about £8,000, making a total of £56,700. During the construction of the mill, profits from the leases should accrue to the extent of, say, £15,000, and by the time the money for the second unit of the mill is required, the increased surplus from profits coming in during the next nine months will be amply sufficient for the purpose. Hence the net profits from the milling and mining combined as from starting of the mill will be available for dividends. Stratton's Independence stockholders may be puzzled at the omission in the published statements of any reference to the Cassel process. On inquiry, however, your correspondent is informed that in Mr. Argall's full report to the board, described as "a bulky document of a highly technical nature," the use of the Cassel filter is contemplated. Your correspondent has dealt somewhat lengthily with the scheme in question in the belief that the particulars given in his classified statement may be of interest not only to Stratton's Independence stockholders but to owners of other mining properties similarly situated. That considerable attention to the subject has been evoked is demonstrated by the fact that several offers from both sides of the Atlantic have been made by responsible parties to lease the Independence mine and dump. With regard to these negotiations it is understood that the directors, while recognizing that they are dealing with a proposition in the nature of a pioneer operation on a commercial scale, they are so confident of obtaining the results estimated by their consulting engineer that they prefer to advise the stockholders not to part with their property on a royalty basis.

American mining returns announced for May: The Tomboy mill crushed 9,200 tons of ore, yielding bullion to the value of \$69,000. Concentrate shipped 540 tons, estimated to realize \$33,500. Ordinary expenses for the month, \$43,000. Expenditure on construction or improvements (not included in ordinary expenses), \$5,900. The directors have declared a 12th dividend of 5 s. per share, free of income tax. At the Camp Bird, the mill crushed 6,562 tons of ore (dry weight), yielding 9,051 oz. bullion and approximately 518 tons of concentrate. Profit in America on sales of product during the month was \$146,464.

Mexican mining returns for May: El Oro Mining & Railway Co.; the No. 1 and No. 2 mills together crushed 23,375 tons of ore, producing \$208,168, less for working expenses, \$97,752, and for development expenses, \$12,475; total, \$110,227, equal to \$4.71 per ton; net profit, \$98,211. The profit from the railway for the month was \$12,249; total for mine and railway, in America, \$110,490. Esperanza: The mill crushed 44,168 tons of dry ore.

Concentrate shipped to smelter, 421 tons. Estimated realizable value of bullion produced, \$158,522; ditto of concentrate, \$103,907, making \$262,429; receipts from rents and other sources, \$476; total, \$262,905. Less working and administration expenses, \$120,108, profit in America \$142,797. Feet of development work, 1,060. The Dolores Company has had a banner return for May, coupled with more favorable news from the mine. Production \$115,000, expenses \$40,000, profit \$75,000, (£15,000). The mine manager states that the ore generally throughout the stopes had been exceptionally high-grade. Referring to stope-block No. 15 he reports the vein as from 6 to 10 ft. wide, running from \$180 to over \$500 per ton. With regard to development work the drift north at the 4th (bottom level) after passing through barren ground has again come into ore, 15 carloads of which gave an assay of \$59 per ton. On this the manager remarks: "The raise has demonstrated that the ore comes down from the third to the fourth level, so we can count reasonably on having a big block of ore between these two levels."

Denver, Colorado.

High Water at Lake City.—Western Federation of Miners.—Stratton Inheritance Tax.—Smelter Rates.—Production of Cripple Creek.—Denver Mint Scandal.—Tomboy Mines.

The Hidden Treasure mine, near Lake City, has been obliged to close down temporarily since the high water

A Part of Colorado.

of last Sunday washed out its dam and pipe-line. As a result of the break much damage was done to the wagon-road and railroad, especially to the bridges. Traffic will be greatly impeded for some time.

The leaders of the Western Federation of Miners, who have been for some time attempting to graft active socialistic politics upon that body, have succeeded, at least to the extent of having a preamble to that effect adopted by the convention in Denver. Before this can become a part of the constitution it must be also approved by the rank and file of the membership on a referendum vote. In all probability the result of the referendum will be the approval of the new policy by the majority, and it is likely that those who still entertain reasonable and sane

views of their duty to civilization, and of civilization to them, will leave the Federation in disgust, and the organization will become frankly what it has always been in effect, a band of "undesirable citizens" organized to upset the order of things as they are.

The Stratton inheritance case, which has been dragging through the courts for some time, has at last been finally adjudicated, with the result of upholding all the contentions of the State. The inheritance tax on the estate of the millionaire mine owner, that on the amount given to Harry Stratton, and the interest on these from the time when due, amounts to \$374,816. The contention of the State was that interest was due from the date of the death of the testator, in 1902, while the executors held that it was only due from the date of the appraisal of the estate, four years later. Unless a motion for a rehearing is filed, the matter is now finally disposed of.

A committee of the American Mining Congress is engaged in investigating the rates and charges of the group of smelters ordinarily known as the 'trust.' The penalty on copper ores seems to be the main bone of contention, and the committee seems to be much wrought up over the fact that shippers may send their copper ores to Utah and have them smelted without a penalty, while one is exacted at the Colorado smelters. This they propose to remedy by a method not yet made public. Most probably they will find that the simplest way will be to find enough copper ores to keep copper smelters going in Colorado.

The output of the Cripple Creek district in June was \$1,288,195, the tonnage being over 54,000. The increase in tonnage and decrease in value of output compared with the last few years is due to the steady advance in the exploitation of the lower grades of ore. The large tonnage handled by the new Golden Cycle mill has somewhat cut down the amounts handled by the other mills of Colorado City, but the latter are saying nothing, only biding their time until the treatment rates go up again. The small cyanide mills in the district continue to operate with good success, and more than one new one is being pushed to completion.

Much stir was caused recently by the statement that the coinage of the Denver Mint had become debased through the carelessness and inefficiency of the officials in charge. The investigation made by the Federal officials has gone to show that nothing criminal had taken place, and the irregularities were simply the result of careless and improper work.

Denver has recently attracted the attention of the Federal authorities in other ways. Last week nine promoters of fraudulent mining companies were arrested for improper use of the mails. The men are promoters of the Goldfield Golden Glow Mining Co. and of the Gold Leaf Consolidated Mines Co., both of which have been advertising themselves as owning fabulously rich properties. The example that will doubtless be made of them, it is to be hoped, will serve to deter such others as may prefer to exploit credulity rather than mineral wealth.

The Tonboy Mines Co. of Telluride has just declared a dividend of \$562,500 for the past year. Out of the profits of the company \$100,000 has been set aside for improvements in the mining and metallurgical processes, by which it is hoped to make an additional saving of \$1 per ton, with a correspondingly larger dividend for the year to come. The 2,100-ft. level is now being opened up, which will add largely to the reserves, and enable the assay value of the ore sent to the mill to be lowered to the average of the mine. Car shortage, bad roads, and the fact that smelting facilities are not available, has held the monthly output of Leadville for two months past at about 75,000 tons.

Butte, Montana.

Production in June.—A Decrease.—Output of the Companies.—

Fire in the Minnie Healey.—East Butte Development.—

Colusa-Leonard Extension.

The copper production from the Butte mines in June was 26,161,350 lb. against 29,017,550 lb. in May. There were a number of interruptions to work, and the strike of teamsters, which continued throughout the month, caused an almost complete suspension of mining by individuals and small operators who have to depend on teams for the transportation of ore to the railroads and smelters. The smelters of the Amalgamated and Clark appeared to back the ore-hauling concerns, for they refused to treat the ores of such companies and lessees as paid the demands of the strikers. The strike also forced a suspension of mining at the Gallatin and J. I. C. mines of the Anaconda, which produced from 200 to 250 tons of ore per day. It had been the general expectation that the Butte companies would in 1907 eclipse the copper production of 1906 by 10,000,000 lb. or more. So far the production has fallen behind that of last year about 8,000,000 lb., the decrease having been due to many causes, including a long term of unusually cold weather, fuel shortage, labor troubles, etc. It is therefore likely that instead of the production being 10,000,000 lb. in excess of that of last year it will be at least that amount short of the production of 1906.

The statistics of production in June are as follows:

Company.	Tons of ore.	Pounds of copper.
Boston & Montana.....	100,500	6,834,000
Anaconda.....	123,000	7,380,000
Butte & Boston.....	19,500	1,209,000
Washoe.....	10,650	628,350
Parrot.....	11,250	630,000
Trenton.....	12,000	708,000
North Butte.....	37,500	3,003,500
Coalition.....	45,000	2,970,000
Original.....	24,000	1,488,000
East Butte.....	6,750	526,500
Pittsburgh & Montana.....	7,500	525,000
Miscellaneous.....	3,000	225,000
Total.....	400,650	26,161,350

For a week operations in the Minnie Healey mine of the Butte Coalition Co. have been suspended on account of a smoldering fire between the 600 and 700-ft. levels, the gases from which drove the miners out of the mine. The fire originated through spontaneous combustion in some old workings that had been filled by former owners with all sorts of rubbish. The fire burned for several days before the gases became so bad that work had to cease, and miners were even driven out of the Leonard and Colusa mines of the Boston & Montana Co. which adjoin the Minnie Healey and connect with it. It was with great difficulty that the fire could be placed, but when that was done air was sent into the burning portion of the mine and all the smoke and gas forced out through the Minnie Healey shaft, which soon made it possible to resume mining in the Colusa and Leonard and on the lower levels of the Minnie Healey. The fire is being closely confined by bulkheads and cement walls, and openings have been drilled from the surface so as to introduce water. It will be some time before the fire is thoroughly extinguished, but the danger to the miners and the interruption of work have been overcome. The incident recalls the fact that in 1889 fire broke out in the St. Lawrence mine of the Anaconda Co. and all efforts to extinguish it have to this day proved futile, the fire constantly feeding itself on the combustible minerals in the ore. The fire area has, however, been thoroughly enclosed by a thick cement wall, and it cannot spread except deeper into the earth. Some portions of the mine are

almost unbearably hot. When the fire has burned itself out, if it will ever do that, this natural smelter will be broken down and the smelted product will be taken out.

The Davis-Daly Co. has decided to do some diamond-drilling on the 500-ft. level of the Smokehouse. The company has been driving on the vein and encountered some ore, but the vein became badly broken up and displaced. After exploring the ground in several directions without finding the orebody, the company decided to do further exploration with diamond-drills.—In another month the East Butte Co. will have connected its No. 1 and No. 11 shafts by a cross-cut. The two shafts are near the extreme limits of the property, and between them are nine other shafts, half of which are operated by lessees. The cross-cut from No. 11 has cut two veins and the one from No. 1 five veins. Of the latter the last one cut is more than 20 ft. wide, 18 in. of it being first-class ore and the remainder concentrating ore. The entire level is in what is known in the Butte district as the lean zone, which terminates in an iron cap overlying a secondary enrichment of the veins. This iron cap was penetrated by No. 1 shaft near the 600-ft. level and was found four feet thick. It remained in the shaft for some distance and immediately below the shaft cut into a good grade of ore which, at the 800-ft. station, carried considerable glance and had widened to two feet. The mining is almost entirely in the hands of lessees, who pay the company a 25% royalty, which is about the average royalty paid in Butte, though in some mines, notably the Ophir, lessees pay 35% to the company.

The Colusa-Leonard Extension Co. has contracted for a new first-motion hoisting engine having a capacity for 2,000 ft. The new compressor is in operation. A new electric pump with a capacity of 400 gal. per min. has also been ordered. The company has had some trouble in handling the water and sinking was impeded. The shaft is now 740 ft. deep and the company expects to reach the 1,000-ft. point late in August. Some exploration may be done at that depth, but the shaft will probably be carried to a depth of 1,500 ft. before any extensive work of that character is done, it being demonstrated by operators on the east side that great depth is required to get into good ore.

Mexico City.

Railway Consolidation.—The Mexican Central.—Wretched Service.—Fire in the Palmilla Mine.—Awakening of Parral.—The Cienega de Olivos District.

There is not a mining man in the Republic of Mexico who does not look forward anxiously to the final arrangements for the merger of the National lines of Mexico with that of the Mexican Central railroad, which has been so long in contemplation; this was authorized by the Federal congress, and yet now for some unknown reason it seems to be held in abeyance. Scarcely any complaint is heard against the service of the National lines, which are more or less under Government control, and proper service is obtained. But the service of the Mexican Central is beyond all power of conception by one who has not actually experienced it. This company has apparently been looking forward to a sale for some years and has done all in its power to make a good showing of earnings by wholly neglecting its roadbed, its rolling stock, and its clerical service, until now it is conceded throughout Mexico that once a piece of freight gets into the hands of the Mexican Central the chances are even that it will never be seen again; if it is not lost in a wreck then it is lost in or stolen from some warehouse at a division point (if it is a small piece) or thrown on some siding there to remain (if it is a carload). The writer

knows of an instance where a mining company on the line of the Mexican Central was 28 days in getting a carload of supplies from that road after the car had actually arrived at the mining company's receiving station. Is it any wonder then that there is a shortage of cars and that there are some 70,000 tons of ore and 30,000 tons of fuel belonging to the American Smelting & Refining Co. are hung up along the lines of the Mexican Central? And now the shortage of cars is to be greatly aggravated by the order issued this week by the Santa Fé to the Mexican Central that if the cars of the former are used by the latter even for hauling goods from Mexican points to the States, the former will refuse to allow its cars to be taken onto the Central's lines. Trainloads of Santa Fé empties are seen going north on the Central and thus shipments that could have gone north in these foreign cars must wait for other cars, and undoubtedly the action of the Santa Fé will be followed by other lines in the

Montana.

United States. It has come to such a pass that some mines have had to close down by reason of not being able to move their ores, and none of the smelters are running full blast because of shortage of ores and fuel. In addition to the shortage of cars on the Central there are periods on some sections of the line when there is no water for the engines; and this condition is allowed to continue when, in my opinion, the geology of the country is such that there is scarcely a point along the lines of the Mexican Central where artesian water could not be found if the wells were driven. Will the Government control straighten out these matters? It is to be hoped so, and so believed.

Report has it today that the famous Palmilla mine which made a millionaire of Pedro Alvarado, formerly a poor miner, was last night entirely destroyed by fire. If this is true it means a great loss to Parral, for the Palmilla pumps drained a large area that had not reached the depth of the Palmilla. This remarkably rich property, by reason of ignorance of the proper system of handling large bodies of ore, had been getting into a bad and really dangerous condition of late, and it was with a feeling of great relief to all Parral that it learned last week of the deal whereby one, a mining man so well known as Bert Peterson, was to take hold of the property. Mr. Peterson has for years been associated with J. F. Johnson in the latter's many holdings in Parral, so that a looked forward to his making a model mine of the Palmilla. But now a disastrous fire has changed the complexion of things. The general effect, however, may be beneficial, for Parral has been a little slow in coming to the mark and keeping abreast of the times in the way of modern equipment and improved methods, both in the

line of mining and in the treatment of ores, and this in a camp which is shipping out close to 300 tons of ore daily, besides treating a like amount locally. But the last year has seen quite a lot of new men taking hold of important interests. Among the more prominent of the new workers may be mentioned the Veta Colorado Mining & Smelting Co., which is erecting a 250-ton concentrating mill, the first for Parral, which it is expected to have completed early in September, and a cyanide plant may be added before the end of the year; El Rayo Mines Co., of J. B. Farrish, 40 Wall St., New York, and associates, which has been organized with a capital of only \$100,000, but contemplates taking over El Rayo Mining & Development Co., Descubridora Mining & Development Co. (of Johnson & Peterson), and the Buena Vista Consolidated Gold Mines Co. (known as the Wm. V. Pettit holdings), near Los Azules in Santa Barbara, and under the management of Bert Peterson, will greatly increase their production; and the Hinds Consolidated Mining Co., which is building a spur from the Santa Barbara station to its Clarinas and Reforma mines, which on the completion of the spur some time in September will greatly increase their already heavy shipments.

The Cienega de Olivos district is attracting attention at the present time. This district is by no means new, for in 1903 this tract was practically all denounced, but a large portion of it was afterward forfeited, and with the exception of one or two properties, work was abandoned. One of the properties, the Delfina, owned by the Hidalgo Mining & Milling Co., has been working steadily, and lately made a rich strike in copper ore, which has led to many new denouncements around this property, and the district is rapidly being taken up again. These denouncements are in the Municipalidad de Cienega de Olivos, Distrito Hidalgo, and 50 miles northwest of the city of Parral. The district is divided into three portions, the southwestern part being a gold-copper-silver section, the central-eastern part being largely copper, and the northern part gold. The recent shipments made from the Cienega de Olivos district run 24 to 26% copper, and 600 to 700 grams silver per ton.

Salt Lake, Utah.

Shipments From Park City.—Labor Unrest at Bingham.—Activity at Tintic.—Several Dividends.—Output at Local Smelters.

The ore output from the mines of Park City during the month of June reached a total of 7,579 tons. Last week 1,596 tons were dispatched to the smelters, the contributing mines and amounts being: Silver King, 709; Daly West, 450; Daly Judge, 135; Little Bell, 80; Daly, 47; lessees, 175.—The Nevada Douglas Copper Co., which has headquarters in this city, has purchased the Ludwig copper mine at Yerington, Nevada. The first payment has been made and the mine is now in the hands of the Nevada Douglas Co. The erection of a smelter is under consideration. Walter C. Orem, of Salt Lake, is manager.—At the recent annual meeting of shareholders of the Consolidated Mercur Gold Mines Co., John Dern, G. H. Dern, H. W. Reed, E. H. Airis, and J. E. Frick of Salt Lake; A. W. Chesterton of Boston, and H. A. Bingham of Jersey City, N. J., were elected directors. The annual report will not be issued until about August 1.

There is much uneasiness among the operators at Bingham over the labor situation. The mining companies find it difficult to get sufficient help and agitators are taking advantage of this condition to talk higher wages. A strike of union miners in these camps is not unlikely. At Tintic, as well as at Bingham, a voluntary raise in wages was announced by the mining companies

not long ago.—The Centennial Eureka Mining Co. is installing a new steel building over its hoisting plant in the Tintic district as protection against fire. The company recently brought suit against the Bullion Beck & Champion Mining Co. to confirm its title to the Solid Muldoon and two adjoining mining claims. There is a great deal of activity in the eastern end of the Tintic mining district. A number of new companies have been recently formed. Recent developments in the Colorado, Beck Tunnel, and several other mines have had the effect of creating much interest in Tintic stocks on the Salt Lake Exchange, and prices in many instances have risen to boom figures. The Colorado has been marketing ore netting as high as \$10,000 per car.

Construction work is progressing favorably at the new smelter to be operated by the Tintic Smelting Co., and it is hoped to have the plant ready by the end of the year. The grading of the Eureka railroad, which is to operate

Utah.

between the principal mines and the smelter, is also progressing satisfactorily.—The ore and bullion settlements reported by Salt Lake banks for the first six months of the year reached the sum of \$14,913,600.

The National Ozokerite Co. has resumed the operation of its milling plant near Colton. Fifty tons of ore are being treated from which a mineral wax product is being manufactured. The Mormon church has sold the Grass Creek coal mines near Coalville, the purchaser being a syndicate of Salt Lake and Eastern capitalists. The consideration is said to have been \$250,000. The property is to be better equipped with a view to increasing the output of the mines. The Grass Creek company owns about 1,000 acres of land and operates a line of railroad 6½ miles long.—The management of the South Columbus Consolidated Mining Co., operating at Alta, Utah, has decided to put in a large air compressor and erect permanent mine buildings. By the time the proposed improvements are installed the mine will be as well equipped as any in the district.

The Newhouse Mines & Smelters Co. has ordered the payment of its first dividend of 50 cents per share, or \$300,000, on August 25. The May Day Co. has resumed dividend payments and will distribute \$8,000, or one cent per share, during the present month.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

MAGNESIA as an adulterant for paint has not been found as good for the purpose as baryta, as it does not take up oil so readily, and it settles to the bottom in the manufactured paint. As a result the paint men have given up the use of magnesite.

DEPOSITS of gypsum large enough to be worked for plaster are often quite impure. Gypsum, as excavated for a plaster plant, will usually carry varying and often high percentages of such impurities as clay, limestone, magnesian limestone, and iron oxide.

INGOT STEEL is steel cast into an initially malleable mass and containing so much carbon or its equivalent that it hardens greatly on sudden cooling. The word is rarely used in practice, but 'hard steel,' 'high-carbon steel' or 'half-hard steel' are used in its place.

ONE gallon water (U. S. Standard)=8.3389 lb., usually taken as 8½ lb. One cubic foot of water distilled (U. S. Standard)=7.48052 gal., usually figured at 7½ gal. One cubic foot of distilled water (British Standard) barometer 30 in., 62° F.=62.321 lb. 27,192 gal. of water are required to cover one acre of land one inch deep.

OZOCERITE is a natural paraffin, and is used for making shoe and leather polish, sealing wax, pencils, rubber adulterant, candles, and pomades, and for insulating electric wires. High-grade black Brunswick varnish is made from manjak, which is a form of asphaltum found on the island of Barbados and elsewhere in the West Indies.

THE mineral anhydrite is closely related to gypsum, being an anhydrous lime sulphate, with the formula CaSO_4 . It therefore corresponds in composition to the product which would be obtained by heating gypsum so strongly as to drive off all of its water of combination. Anhydrite occurs, but usually only in relatively small quantities, in almost all gypsum deposits.

THE supply of antimony ore marketed continues to be exceedingly small. China for the last five or six years has produced the greatest quantity of ore, but there has been a heavy falling off in these shipments. This may be explained partly by the manipulation in ore by speculative interests in China, and perhaps to a more marked degree by the sudden and unexpected exhaustion of certain mines in that country.

FROM Ears Mtn., 40 miles east of Cape Prince of Wales, specimens of supposed tin-bearing rock have been brought by a number of parties; but, although tin ore has undoubtedly been found there, the minerals taken for cassiterite are, more often than otherwise, either tourmaline or augite. What the extent of the deposits may be is wholly unknown. Some stream tin has been found in the creeks heading in the mountains.

THE chief use of tungsten is in the manufacture of tungsten steel, and this again is mostly used for high-speed tools, magnet steels, and in European countries also for armor plates and projectiles. The percentage of tungsten in tool steels varies greatly, according to the special uses for which they are intended, but tungsten always imparts to the steel the property of self-hardening

in the air after forging without necessitating any of the usual methods of tempering.

STEELS containing a low percentage of chromium are tough and perform excellent work on the softer varieties of steel and cast iron, but when tried on harder materials the results obtained are not so good. With an increased content of chromium the steel becomes much harder, and greater cutting efficiency is obtained on hard materials. It has been observed that with an increase of chromium there must be a decrease in carbon to obtain the best results.

THE Florida phosphate rock deposits extend in a rather narrow curved belt at a distance of about 20 miles from the Gulf of Mexico and approximately parallel thereto for nearly 300 miles from near Punta Gorda on the south to a point west of the Apalachicola river on the northwest. The hard rock deposits of the Eocene beds consist of transported materials, but those of the Miocene strata are in place, though there are some boulders of foreign origin.

THROUGHOUT the great semi-arid and arid region comprised within the boundaries of Idaho, Utah, and Nevada there are extensive surface deposits of salt, some of which are associated with bodies of water, while others are not. The most famous of these is the Great Salt Lake of Utah and its immediate vicinity. The salt is won from the brine by simple open-air evaporation in great shallow artificial ponds, care being exercised not to allow the bitter salts of the lake waters to precipitate.

THE principal commercial source of salt in Kansas is the deposits of rock salt in the Permian strata of the central and south-central part of the State. About one-half the production is from direct mining; the remainder is from artificial brine made in wells driven down to the deposits. Salt is also found in salt marshes, or 'salines,' where it has been brought by leaching from clays associated with the Dakota (Cretaceous) sandstone, and in some of the Pennsylvanian beds of the eastern part of the State.

THE oil-asphaltum produced by the refineries from California crude oils is the result of doing artificially what has been done slowly by nature at several points in the State. The manner of manufacture was described at length in the report upon the production of asphaltum and bituminous rock in 1904. The process consists in careful and comparatively slow distillation of crude oil at uniform and definite temperatures. The value of the product depends upon the skill and care of the refiner. Several grades, varying from a highly viscous liquid to a hard brittle solid at ordinary temperatures, are made, which are adapted to the uses to which the product is to be put.

THE most important beds of phosphate rock are those of Florida, more than three-fifths of the total tonnage for the United States being produced in that State, with a value nearly two-thirds that of the total production for the country. The phosphate rock of Florida is divided by Eldridge into hard rock, containing about 36.65% phosphoric anhydride, corresponding to 80% phosphate of lime; soft rock, usually averaging less than 22% phosphoric anhydride, 50% phosphate of lime; land pebble, averaging 32% phosphoric anhydride, 70% phosphate of lime; and river pebble, averaging 20% phosphate anhydride, or 45% phosphate of lime for the Black Creek deposits, and 28.40%, 61% phosphate of lime, for the Peace River beds.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A Question of Practical Mining.

The Editor:

Sir—Your editorial of June 8 on 'A Question of Practical Mining' came to hand just as I was preparing a rough draft on 'The Cross-cutting Evil.' I had in mind especially the cross-cut adit; your editorial placed most of its emphasis on the vertical shaft in country rock. In effect they are the same, except that the shaft-sinker rarely gets as far from the lode as the bold 'cross-cut tunnel' man is likely to do. In some few camps, of which the Cœur d'Alene is perhaps the most striking example, the orebodies are so persistent and continuous that cross-cutting from the nearest gulch has in many cases been the most successful and satisfactory way of opening up the deposits. But the success of the few has led to the failure of the many, the minority's meat has been the majority's poison, and foolish cross-cutting has wasted more money and led to the abandonment of more promising properties than any other one thing.

Time after time throughout the entire West, from Alaska to the Mexican line, have I seen a man with a fair surface showing, sink a 10 or 20-ft. hole and on the data, as to dip and strike, so obtained, leave the only good thing he had in the world and hie himself and his miners to the nearest ravine to begin cross-cutting. Sometimes the surveyor is called upon for direction, but usually that is considered a superfluous detail, and our friend and his force start off through a mile or more of the toughest kind of country rock, to open up a quantity of ore, the tonnage of which is limited only by the prospectus writer's imagination. The results are rarely worth recording. The only camps in the West that do not afford instances of this stupendous folly are those of southern Nevada, where tunneling is impossible because of the topography.

"Stay with your ore, boy, stay right with her," my old California partner used to tell me, and that bit of philosophy should be blazoned in box-car letters on the walls of mining companies' offices and miners' cabins alike. Those of us who have crept through powder smoke to scan the last traces of the streak we were following, know what changes a single round may show and realize how easily the lode may be lost without going thousands of feet away to explore the adjacent formation.

If the deposit is in such a situation that an adit can easily be driven to take out the ore, put in the adit after sinking on the vein, and then (if time is a consideration) the adit level may be driven both ways.

There is no sense in being afraid of a little hoisting during the prospecting stage. A windlass is good for the first 50 ft. (or 125 if necessary), and a good stout whim-horse, whim, and tripod are good for 250 ft. as long as water is not a serious consideration. A small steam-hoist, if water and fuel are plentiful, or if not, a gasoline hoist, need be no great item of expense, and will generally pay for itself after the first 100 ft. In addition, if the property is one with which men of small capital can afford to deal, the ore taken out should be paying for its extraction and possibly contributing to a treasury fund for the adit to be driven when the vein has been proved.

FRANCIS A. THOMSON.

Pullman, Wash., June 26.

Vacuum Slime-Filters.

The Editor:

Sir—In view of the articles that have appeared from time to time in the columns of the MINING AND SCIENTIFIC PRESS as to the merits of the Moore and Butters systems of vacuum-filters, having had some experience with both, I would like to add a few remarks to the general exchange of ideas through your columns.

I do not think there is much difference in either system as far as cost of operation and maintenance is concerned, but I do think there is considerable difference when it comes to the maintenance of the best conditions for the highest efficiency in the vacuum type of filter. It makes no difference which of the two filters mentioned is used for making the cake, as, with a given vacuum and pulp conditions, either of them make a cake equally fast. Therefore, it comes to a question of displacing the pregnant solution contained in the finished cake by barren solution or water.

The best conditions for perfect displacement are obtained by having a homogeneous mixture of the pulp in the filter-box throughout the time of making the cake and by maintaining uniform conditions until the end of displacement, when the deposited slime is ready to be discharged. By uniform conditions, I mean a constant vacuum, constant hydrostatic pressure, and as little exposure to the air as possible. Under these conditions I find that the displacement is almost perfect, no appreciable decrease in strength of cyanide being noticeable until nearing the finish of displacement, when the decrease is rapid down to the strength of the barren solution with which the washing is being done, which shows a displacement of the pregnant solution contained in the cake, with very little dilution.

Dilution, when displacing with water or barren solution, is to be avoided, as it means a larger amount of solution to be passed through the zinc-boxes, and, in the event of water being used, it also means a larger quantity of waste solution.

The methods of operation of both the Moore and Butters filters have been given at some length in your columns at various times, but for the purpose of comparison I shall briefly outline them again.

In both systems the storage, or equalizing-vat, is placed to one side of the filter-box, pulp being drawn from it to keep the leaves of the filter submerged during the formation of the cake.

In the Moore system the whole nest of leaves (which are attached to a frame) is removed from the filter-box by a traveling crane and delivered into a displacing-vat, which is immediately alongside the filter-vat, the vacuum being maintained during the moving of the loaded nest of leaves to the displacing-vat. The unit is composed of three filtering-vats, two for displacing, and one in the centre for loading.

When the crane has removed the filters from the loading-vat and deposited them in the displacing-vat, it is disconnected and taken to the other nest of filters, which are in the other displacing-vat, and when the slime-cake on the filters is discharged they are brought over into the loading-vat, and the making of the cake commences without loss of time.

In the Butters system the filters are stationary in the filter-vat, and, when the cake is made, the pulp is pumped back into the storage-vat, the vat is washed out with solution and is then filled with water, and displacement commences. When finished, the cake is discharged, the surplus water is run back to storage, and the discharged slime is sluiced to waste. The vat is again sluiced out to remove any particles of the discharged

cake adhering to the sides, and again pumped full of slime for the next cycle of operations.

A comparison of the time consumed for a complete cycle is as follows:

MOORE SYSTEM AT LIBERTY BELL MILL, TELLURIDE, COLO., JANUARY, 1906.		Hr.	Min.
Making cake.....			45
Transferring from loading to displacing-vat.....			5
Displacing or washing cake.....	1	0	
Sampling.....			5
Discharging.....			15
Transferring from displacing to loading-vat.....			5
Total time per cycle.....	2	15	

BUTTERS SYSTEM AT COMBINATION MILL, GOLDFIELD, NEV., MARCH, 1907.		Hr.	Min.
Filling filter-box from storage.....			25
Making cake.....			30
Pumping pulp from filter-vat back to storage.....			22
Filling filter-vat with waste solution or water.....			20
Displacing or washing cake.....	1	0	
Sampling.....			5
Discharging.....			15
Running surplus wash solution to storage.....			6
Sluicing out discharged slime residue.....			8
Total time per cycle.....	3	11	

In comparing the above tables for time consumed by the various steps in each system, it will be noticed that the transfer from the loading-vat to the displacing-vat in the Moore system occupies five minutes. During this short period of time the vacuum is fully maintained; therefore, there is no change in this particular part of the operation; the exposure to the atmosphere is short and the change from the hydrostatic pressure of the pulp on the finished cake to that of the water on the same in the displacing-vat is rapid.

In the Butters system the transfer of the remaining pulp back to storage after the cake is made occupies 22 minutes; the pumping of the water for displacing (after all the pulp is out) occupies 20 minutes, making a total of 42 minutes from the finishing of the cake before displacement can be commenced. This long period necessitates the vacuum being dropped from 21 to 5 inches.

The difference in total time consumed per cycle, other than in making the cake and displacing, is seen to be 30 min. with the Moore system, and 1 hr. 11 min. with the Butters, the saving in favor of the Moore system being 1 hr. 11 min. per cycle, but the saving of time is not the only consideration.

The length of time occupied between finishing the making of the cake and the commencement of displacing it in the Butters system necessitates dropping the vacuum down to five inches, or barely sufficient to hold on the cake, otherwise the cake would be so badly air-cracked that displacement would be impossible. (A three-quarter inch cake under 18 in. vacuum will crack beyond redemption in seven minutes.)

When the vacuum is lowered, after finishing the cake, much of the moist exterior portion of the cake drops off when the hydrostatic pressure is removed, it being a difficult matter to adjust the vacuum at the best point for any particular cake; for if too high, the cake will be badly cracked; and if too low, the cake has a tendency to slough off.

In the 12 min. consumed in pumping the pulp back to storage and the water into the filter-box for displacement, the extreme top of the cake is exposed for the full period of time to the atmosphere and the low vacuum that is maintained, the pulp recedes slowly down the cake during the pumping out of the pulp, and the cake is slowly submerged during the entrance of the water. Therefore, there is a period of time (about 26 min.) in which the extreme upper half of the cake is exposed to the air longer than the lower half, and with sufficient vacuum to hold the cake on the filter-leaf there is also

sufficient to cause displacement as the water slowly rises with the result that the pregnant solution in the lower half of the cake is thoroughly displaced long before that in the upper half and a large amount of dilution occurs, as the large quantity of weak barren solution necessary for displacement goes to prove, at the Combination plant it being four and one-half times the amount of moisture contained in the cake before displacement.

It will be seen that in the time schedule of the cycle of operations the Butters system will have to be considerably changed to allow of the best working conditions. And I consider it preferable to use one vat for loading and a separate vat for displacing, as then the small loss of time necessary for washing out the filter-box when changing from pulp to water and the reverse are avoided, and it also avoids the constant small losses that are bound to occur by this method through mixing of small amounts of pulp and pregnant solution with waste solution when they go through the same system of pumps and piping, and the richer the solution the greater the loss.

The wide difference in the capacity of the two plants makes it difficult to give a just comparison of the cost of operations, the Liberty Bell plant at Telluride having a capacity of 450 tons per day and the Combination Mines plant at Goldfield 193 tons per day as at present equipped.

The labor employed at the Liberty Bell at the time of which I write was two men on each shift, one of whom acted as shift-boss and had general supervision of settlers, agitators, and Moore filters, making all necessary titrations throughout these departments. At the Combination plant, one man on each shift attends to the filter-plant besides making other titrations in the leaching-plant, so that with the small unit as installed, that is, two filter-boxes of 28 and 30 leaves, respectively, one man per shift could possibly handle the full capacity of the plant or 193 tons per day.

The power consumption at the Liberty Bell is two 10-h.p. motors at the transferring cranes and one 40-h.p. motor to operate the vacuum and other auxiliary pumps connected with the filtering system, the same motor also operating a Goulds triplex pump that returns all solution used in milling the ore to the top of the mill, a lift of about 80 ft., requiring about 7 h.p., constantly, the total power consumption being 53 h.p. to charge against the filter equipment. The power consumption at the Combination plant when operating two Butters pumps, which the recent new addition makes necessary (the plant being two units), is 20 horsepower.

The Combination plant, then, with its two units, one of 28 leaves and the other of 30 leaves, can handle 193 tons of dry slime per day when working at a maximum capacity, with labor of one man per shift and a consumption of 20 h.p. The Liberty Bell plant, with its four sets of leaves consisting of 67 each, will handle 450 tons per day when working at maximum capacity, with the labor of two men per shift and the consumption of 53 h.p. Therefore, as far as direct comparison of the actual operating costs of the two plants goes, there is not much difference. But two important items that affect the capacity of the Moore plant at the Liberty Bell, and that so far have not been taken into consideration, are the sticky nature of the ore handled and a difference of 3,000 ft. greater altitude.

In taking up the question of maintenance it will be noticed that the total number of leaves in the Liberty Bell plant is 268 against 58 leaves in the Combination plant, hence, allowing for an equal life in each case, the renewal cost for this item on the Moore plant will be almost five times as great as on the Butters plant at the Combination, but the rule previously mentioned still holding good, that a given pulp and vacuum condition

will produce the same cake in either system, the Moore plant at the Liberty Bell if working on Combination ore would have a capacity of 805 tons per day against 193 tons per day of the present Combination plant. In the moving parts of the crane in the Moore system, the main item for expenses for repairs is the renewal of the lifting cables, which require renewing about once a year if properly adjusted when put on. The repairs that are necessitated by the cranes are offset by the repairs to the centrifugal pumps in the Butters system. With the Moore system, where heavy loads of slime are moved from one vat to another, there is always the possibility of accidents, for instance, a cable breaking and causing a bad wreck, running up the repair bills rapidly, but with properly designed apparatus the probability of such an occurrence is very remote.

It is supposed that the moving of the filters greatly lessens their life by straining the canvas; such is not the case, as one cannot feel the least jar when the crane starts to lift, the vertical velocity being only seven to eight feet per minute while hoisting the loaded baskets and the same when lowering into the displacing-vat, and there is apparently no more difference in the cake or filters after moving than if they had not been removed from the loading-vat. The suspended load on each filter-leaf is the same in either case, whether the filter with its load of slime is removed from the vat full of pulp, or the pulp removed from around the filter, the only difference being in the length of time the filter is required to sustain the load of slime, unaided by hydrostatic pressure of either pulp or water, which maximum length of time is seen to be five minutes in the Moore system to 44 in the Butters.

In a comparison of costs of installation, a 58-leaf plant such as is used in the Combination mill will be taken and the main items of necessary material for each one tabulated.

BUTTERS SYSTEM.	MOORE SYSTEM.
2 1 by 10 ft. filter-boxes.	3 11 by 10 ft. filter-boxes.
1 14 by 12 ft. pulp storage-vat.	1 14 by 12 ft. pulp storage-vat.
1 14 by 12 ft. water " "	1 12 by 10 in. vacuum pump.
1 12 by 10 in. vacuum-pump.	1 10-h.p. motor.
2 4-in. Butters centrifugal pumps.	1 20-ton crane equipped with
1 20-h.p. motor.	1 10-h.p. motor.
58 filter-leaves.	1 4-in. centrifugal pump.
	58 filter-leaves.

It will be seen that the Moore system requires three filter-boxes against only two needed in the Butters, only one storage-vat being needed, and that for pulp in the first instance, as against two in the second; and a 20-h.p. motor against two 10 h.p. The main difference in the cost of installation is in the crane, which will add 35% to the total cost of the plant. The above equipments comprise an equal filtering-area in each case. The Moore system will handle 22 charges in 12 hours, and the Butters system 10 charges in 12 hr. 44 minutes.

To summarize: The operating costs of either system are about equal, as are also the maintenance and repairs.

The installation cost for the Moore system is 35% greater than the Butters system for an equal filtering-area.

The capacity is 50% greater in the Moore system than in the Butters system for an equal filtering-area.

The efficiency of the Moore system for the recovery of pregnant solution with the least amount of loss and dilution, is higher than the Butters system for reasons previously given.

There is no doubt but that given ideal topographical conditions, the Butters system can be a great deal better arranged than here at the Combination plant.

Where sufficient elevation is available to allow of ample pulp and water storage above filter-boxes, and also the same ample storage below (to again allow for the storage of pulp and water), a great saving of time is

obtainable by allowing the pulp and water to flow in and out of the filter-box rapidly. This would necessarily greatly increase the cost of installation. Under such conditions the amount of pulp and water to be moved back up hill after each cycle of operations would be performed over a long period of time and not obstruct the filtering operation, instead of a short period during which filtering operations must cease, as at the Combination plant.

But even under these conditions, which have materially lessened the time consumed and also improved the conditions for displacement by removing the pulp from around the filters rapidly and getting them quickly submerged in the displacing medium, we have not eliminated the obvious opportunities for loss, that is, by alternately running pregnant solution and water through the same pumps and pipes and into the same receptacles, as a large percentage of the water that in this way becomes mixed with the small amounts of pulp and pregnant solution has to be allowed to run to waste with the discharged cakes of slime. Therefore, the less opportunity there is for any such mixing, whether accidental or unavoidable, the better. Hence my reason for saying that a loading-vat in which the cake is made should be used for that purpose alone. And the same reasoning holds good as regards pipe-lines and pumps for moving pulp containing pregnant solution.

Since commencing this contribution, Mr. E. H. Nutter of the Liberty Bell Mill at Telluride, has given us a further article on the Moore filters in use there, slightly changing the figures as shown in the table I have given for time consumed per cycle, which change no doubt comes from over a year's further experience with the plant. I am hoping that he will furnish us with some valuable figures from recent operations there, and that Mr. Mark R. Lamb will do the same with reference to the more recent installations of the Butters system in Mexico, for the benefit of the readers of the MINING AND SCIENTIFIC PRESS.

A. G. KIRBY.

Goldfield, Nevada, June 15.

PRICES IN KLONDIKE.—The wages of mechanics in the Yukon Territory, per day of 10 hours, is \$10; common laborers, with board, \$4 to \$5; without board, \$6; draft teams, per day (two horses), \$25; clerks, per month, \$150 to \$300. Everything consumed in the way of living costs from two to three times as much in this country as it does in the United States. There is no article sold for less than 25c., no matter how trivial, as there is no money in circulation of a lesser denomination than that amount. The cost of living will remain high as long as the means of getting supplies into the country remain as they are, and what is true of the Yukon Territory is true of the Yukon valley from the Alaskan line to the coast. The only relief suggested for these conditions is a trunk-line railroad from the open sea into the heart of this great valley, to be in some way under the control of Government authority, in order to keep down excessive freight and passenger rates.

COPPER OUTPUT OF CANADA.—The production of copper in British Columbia has increased 800% during the past 10 years, while the remainder of Canada has increased but 50%. The whole of Canada produced 13,300,802 lb. in 1907, British Columbia's share being 5,325,180 lb., while of the estimated 55,000,000 lb. total production in 1906 British Columbia's output was 43,000,000 lb. A Canadian editor states that the dividends declared last year by British Columbia mining companies amounted to between \$3,000,000 and \$4,000,000.

A Tin Deposit Near Spokane.

Written for the MINING AND SCIENTIFIC PRESS
By A. R. WHITMAN.

In the issue of June 1 of this journal there appeared a description, by the writer, of some of the geologic phases of the new tin discovery near Spokane, in which nothing was said about its economic importance. By request, the present article was written in an attempt to give this supplementary information.

The workings of the mine are situated on the south slope of Silver hill, at the foot of which runs an electric railway, belonging to the Spokane & Inland Empire Railroad Co. In direct line, Silver hill is only six miles distant from the limits of the city of Spokane, but the distance of transportation is about 11½ miles.

The ore will have to be concentrated at the mine, and the tin concentrate shipped through Spokane to some smelter. Though water has not yet been encountered in the shaft now being sunk from the west cut, it doubtless

the 60-ft. shaft—the ore going to the mill would have a gross value of \$21 per ton, and a net value of approximately \$14.64 per ton. The East Pool and Agar tin mines of Cornwall, have been worked for 69 years, and in that time have paid \$350 per share in dividends on 6,400 shares of stock, on which only \$23 has been paid up. This profit was derived from ore carrying 1% of recoverable tin, in the presence of arsenic, tungsten, and copper, and which has been worked largely by Cornish methods. It would seem, therefore, that a mine with such good ore and such a favorable situation as the one on Silver hill, ought to compare very well with the Cornish mines, provided only that the deposit be of equal extent.

This question of extent is one that only actual exploration can settle. There are plenty of theories on the subject, but they are inconclusive. They would favor the idea of a large orebody; but actual exposure of this body is a safer basis for estimating its magnitude; and it remains for future development work to accomplish this.

Silver Hill, on the Spokane & Inland Empire Railway.

will be, when this approaches the level of Moran Prairie, which will be only one or two hundred feet. From this source a concentrating plant, built just below the shaft, could derive an ample supply of water. From the drying-floor of the mill a chute or short gravity tram could deliver the concentrate to ore-bins at a siding close to the main tracks. Thus, after hoisting from the mine, the ore would go through the mill to the freight-cars entirely by gravity.

The ore is cassiterite, and is remarkably free from any such impurities as are associated with the output of other tin mines; and the gangue is chiefly a mixture of quartz and aluminum silicate. This makes the ore easy to mine and mill, for the cassiterite, having a specific gravity of 6.9, would be readily separated from the gangue, having a specific gravity of 2.45. The slight tendency of the cassiterite to slime would cause the only complication in the otherwise unusually simple process of concentration. Numerous tests made on the ore have demonstrated that a concentrate running 70% tin could be produced; and the character of the ore together with the favorable situation, would make the recovery and shipment of such a product exceedingly cheap.

If this concentrate should be shipped to the smelter at Tacoma, it would have, at the present price of tin, a net value of \$107 per ton. Then, on the basis of 3% tin—which is the value of the ore on the dump, taken from

It is certain, however, that the deposit as thus far exposed is the richest in the United States, and is well worthy of further exploration.

THE Government of British Columbia, at the session of the local Parliament which adjourned recently, made an announcement that at the next session, which will convene early in 1908, it would bring in a bill requiring that all iron ore mined upon provincial lands should be smelted within the Province. The property upon Texada island was Crown granted years ago, and the new law may not apply to exports from that property. There are many other large deposits of magnetic iron ore upon the west coast of the mainland of this Province. Upon Vancouver island large deposits of bog-iron ore are reported, which will be useful in fluxing the magnetic ores. There are large quantities of hematite ore in the interior. Texada island is rich in limestone, much of which approaches nearly to good serviceable marble. A mining company, operating on the northern end of Texada island, in addition to shipping ore rich in gold and copper, also operates two lime-kilns and supplies a large amount of lime to Vancouver, Victoria, Seattle, and the Hawaiian islands. At the present time a large quantity of pig iron is brought here from Scotland, which the experts pronounce an inferior grade to the pig iron manufactured from the ores of Texada island.

the consecutive number on the report under 'Desc.,' and the grand total under 'Total.' On the last of each month these cards may be transferred to the general account.

To keep track of the supplies consumed, I use a card as shown in Fig. 9, with indices identical with those shown in Fig. 2, and enter them up each day from the daily

the different departments. While this system may seem long in the describing, it is in reality exceedingly simple, as one process follows another in regular order. For a mine employing 100 men the accounts have been kept with this method by one man in three or four hours each day and everything kept in ship-shape all the time; there is no hair-tearing rush at the first of the month to get the accounts for the preceding month into shape, for they are always in shape, with no more to be done on the first of the month than any other day, with the exception of the payrolls and the monthly report, if one is required, the information for which is right up-to-date.

For payrolls I use a book containing double sheets, the top or original sheet being of light white paper and perforated for removal, while under sheet, or duplicate, is of yellow paper and not perforated. They are ruled like a time-book with 31-day spaces and total days, rate, amount, and reduction, and net-amount columns, and a column for signatures. They are made up for the first of each month and the time kept on them during the month, using carbon-sheets between the originals and duplicates and an oiled sheet to keep from copying through. At the end of the month all that is necessary to do to get ready for payday is to

reports. At the end of the month these cards have only to be added to furnish the information for a monthly cost-sheet generally required by the head office.

In Fig. 7 is given a form for a warehouse record, showing the amount of supplies received, used, and on hand—valuable information for the purchasing department. These cards are also entered each day from the daily reports.

For individual accounts I use the card shown in Fig. 8 with a plain, alphabetical index, if the names are used, or a numerical index if the 'Account Number' is used. I have my bills rendered in duplicate, and as fast as they are received and checked, they are stamped with a serial number and entered on the card, giving the serial number for reference under 'Desc.,' and the brief clue to the contents under 'Item.' The invoices are then filed numerically and vertically, just as the reports are filed (Fig. 3). When paying bills, I send the original and duplicate invoices, together with a check for the amount to the seller, and when the bills are receipted and returned, I send the original to the head office and file the duplicate in its proper place. All supplies are charged to 'Warehouse' when received and credited to 'Warehouse' from the totals shown on the daily reports. This does away with the awkward and troublesome vouchers with which most mine-offices are burdened, where a form has to be filled out for each set of bills and the bills distributed to

carry out the extensions. When the payrolls are signed up the originals are torn out and sent to the head office and the duplicates stay in the book. The names are numbered and slips bearing the names and numbers

Fig. 7.

Fig. 2.

are sent to the tally-office about payday and delivered to the men. When presented at the office these slips serve as an instantaneous index to the name on the payroll, besides obviating the necessity for keeping the names on the payroll in alphabetical order. I have never tried this system at a mine employing

The Genesis of Ores.

By HORACE V. WINCHELL.

*Antecedent to every great achievement is a theory or mental conception. Powerful imaginations lead to epoch-making events and discoveries, if to the dreamer is given also the faculty of creating and developing. This is true not alone of mechanical inventions and of processes of commercial importance; but in the elucidation of scientific problems and theories. These new ideas are often received with skepticism and incredulity when first announced; and in many instances have been neglected and forgotten for years, only to be revived at a later date and given general acceptance. From this we should not conclude that every novel theory is worthy of credence and liable to revolutionize matters in its own particular sphere. The true scientist will always maintain a receptive mind ready to advance with the progress of real discovery and the growth of knowledge, be it fast or slow. Indeed, there has been great improvement in regard to this point with the spreading of education; and while the true is more readily distinguished from the false and improbable, there is also greater tolerance and more reasonable and careful consideration of the newer and more advanced theories of mankind than they have ever before received; and substantial progress is increasingly more rapid along all the avenues leading to a more perfect comprehension of our universe.

It has seemed to me fitting on this occasion to sketch an outline of the prevalent modern theories of the genesis of ore deposits, laying special emphasis on some portions of the theory which appear to have received less attention than they perhaps deserve, and which have perhaps not all been incorporated in text-books. It is well understood but often forgotten that all of the constituents of ore deposits are found in some form in the earth's crust, contained in more or less abundance in the rocks, especially in the eruptive rocks; and that they have been in some way collected from their disseminated condition in these rocks, and concentrated in veins, beds, or other deposits.

Analyses of fresh eruptive rocks have demonstrated the existence therein of all of the ingredients of our valuable ores and their compounds. Few of them occur native like gold, silver, copper, and platinum; often, because of their minute quantity and fine state of subdivision, it is not possible to determine the precise form in which they are present. The presence of sulphur, arsenic, antimony, and tellurium indicates that there may be many metallic combinations in the eruptive magmas similar to those formed at later periods, nearer the surface.

The average composition of the earth's crust has been approximately estimated as follows:†

	Per cent.		Per cent.
Oxygen	47.13	Phosphorus	0.09
Silicon	27.89	Manganese	0.07
Aluminum	8.13	Sulphur	0.06
Iron	4.71	Barium	0.04
Calcium	3.53	Chromium	0.01
Magnesium	2.61	Nickel	0.01
Potassium	2.25	Strontium	0.01
Sodium	2.08	Lithium	0.01
Titanium	0.32	Chlorine	0.01
Hydrogen	0.17	Fluorine	0.01
Carbon	0.13		
		Total	100.00

Copper, lead, zinc, tin, silver, and gold, although metals of great importance to man, constitute so small a part that their percentages are expressed by four to eight decimals, that is between hundred thousandths and billionths of a per cent. In some eruptive rocks, however, the per-

centage is much higher, and has been determined to be in the thousandths of a per cent in the case of copper, lead, and zinc, and one tenth to one hundredth as much of silver and gold.

The amount of metallic content found to occur as a primary constituent in unaltered rock is thus seen to be far too small to constitute workable ore, and indeed is often so insignificant as to be determined with difficulty. You all know that several per cent of iron, manganese, zinc, lead, and copper are required to make an ore valuable, the percentage varying, of course, with the locality, complexity of the ore, and other familiar factors. It is therefore apparent that a process of natural concentration is essential for the production of ore deposits, bringing into limited space the material formerly disseminated through 10,000 or 100,000 times that extent of ground, or accomplishing the same result by the removal of the admingled rock impurities. Wherever this concentration is brought about by assembling of solid particles under conditions that admit of freedom of movement we have placer deposits, as of gold and platinum, iron and chromium ores, and sometimes of precious stones, such as diamonds, sapphires, rubies, garnets, and others.

The ores found in veins in disseminations throughout the rocks, and in irregular shaped deposits in soluble rocks cannot have been collected in any such manner. Their mode of occurrence and relation to the enclosing rocks, make it evident that they have been slowly deposited from solution. And the only solvent of general distribution is water, with its varying content of acids and alkalis under changing conditions as to temperature and pressure.

Water is the magic instrument by which all the copper in Butte's vast mines, all the gold and silver of the Comstock and of Goldfield were assembled. More potent than the philosopher's stone, more universal than the air we breathe, constantly at work, dissolving, transporting, and re-depositing. With indefatigable zeal and never-flagging industry it searches through the innermost recesses and penetrates the most closely locked chambers of the rocks, removing treasures through their very walls, and often repairing breaches made in the attack so skillfully as to defy detection, or to make the masonry stronger than when first laid. Small wonder that the ancients regarded it as one of the four prime elements.

But, although for several years water has been recognized as the great agent in the formation of ore deposits, geologists are not agreed as to the source of this water, the conditions under which it is most effective, nor the relative importance of its work in ascending and descending movements.

Regarding its source, we have those who believe with John Woodward, Franz Posepny, and C. R. Van Hise, that the water in the uppermost layers or outer zone of the earth, including the water on the surface and in the atmosphere, accomplishes the formation of ore by means of a perpetual circulation. From the air it falls on the earth as rain; through crevices and fractures it enters the rocks by reason of its head or the weight of more water on top of it, and finds its way deeper and deeper to the very lowest point where the density of the rocks will permit it to penetrate. Down to this depth, which is theoretically not more than five or six miles, the temperature has been constantly increasing, and the water by reason of this higher temperature has been gaining strength as a solvent and picking up alkalis or acids that enable it to hold even the most difficultly soluble substances in solution. Finding no escape downward, and urged on by cooler and heavier waters above, these saturated solutions begin to move laterally and upward, expanding and becoming

*Commencement address delivered before the Montana School of Mines on June 5, 1907.

J. F. Kemp in *Engineering Geology*, Vol. 1, Part 3, p. 210.

of lower specific gravity because of the forced deposition of dissolved material as they become super-saturated. Following the directions of least resistance, these metal-carriers reach the surface as hot springs or geysers through fractures caused by earth movements. Gradually the walls of these fractures become coated with vein-minerals and ores, until the waters stop flowing or the fracture is healed and a vein is formed.

Then there are those like Vogt, Spurr, Weed, and Kemp, who maintain that the chief source of underground waters is the unconsolidated magma of molten lava within the earth. These authorities point to the immense volumes of steam emitted from volcanoes; they call attention to the conclusions of European scientists, who have decided that many of the hot springs cannot be derived from meteoric waters heated and returned to the surface; they remind us that there is so much watery vapor derived from lavas that possibly the oceans themselves were formed from volcanic emissions. They point out the ease with which such waters, thus derived and so heated, could gather metallic substances at great depths and bring them to the places where they are now found. They mention the fact that there is a general association between the more important mining regions and eruptive rocks; and they raise several serious objections to the premises of the disciples of the meteoric water school.

On this particular point we shall not dwell further; it is quite probable that both theories contain elements of truth; and that ore deposits have been formed by both magmatic and meteoric re-ascending waters. It is even possible in some cases to determine by the character of the minerals the origin and nature of the causative solutions.

As to the relative importance of the work of ascending and descending waters there is also divergence of opinion. There are few who still doubt the agency of descending waters in the formation of the oxidized ores, such as carbonates, silicates, and oxides of copper (as also the native metal in some instances), in the superficial or shallow alteration of sulphides, arsenides, or antimonides. The iron ores of the Lake Superior region, for example, are generally believed to owe their concentration to descending solutions; in this respect differing from many of the Scandinavian iron ores, according to recent descriptions.

It is not, however, the oxidized or 'dry' ores alone that are now believed to owe their formation in large part to the action of descending waters; but the 'base' ores consisting of chemical combination of the metals with sulphur, arsenic, antimony, tellurium, and some rarer elements. It is only within the past decade that it has been considered possible that the sulphide minerals are produced by reaction between sulphate or carbonate solutions and undecomposed sulphides or other minerals found in veins. Laboratory experiments have, however, shown that the operation is not only possible, but easily accomplished and duplicated under normal conditions as to temperature and pressure.* This is a fact of great importance and wide significance, for it aids in the explanation of many formerly puzzling phenomena of mines and mining geology.

It has long been noticed by the students of ore deposits that by far the greater number of mines become exhausted at comparatively shallow depths; that veins, instead of continuing downward uniform in size and composition, like dikes of diabase and porphyry, become smaller and of lower value with depth, and often disappear altogether. It is noticed also that the shape of many ore deposits, and the distribution and paragenesis of the

minerals which they contain, can often be better explained on the theory of descending than of ascending mineralizers. Moreover, it is apparent that there are changes constantly in progress in those portions of sulphide orebodies lying nearest the surface of the ground. These changes consist in the oxidation of the sulphides and their solution as sulphates. These sulphate solutions percolate downward into the veins or rocks below along the most open channels; and thus, by degrees, the upper zone of the vein is robbed of most or all of its sulphide minerals, and only a gossan or iron cap remains.

The process of oxidizing and leaching of the sulphides in the superficial zone of ore deposits tends, first of all, to disguise the nature of the unaltered ore below. In many instances the ore discovered by the outcroppings is gold ore; and gold mills are often erected and operated for years upon such ore, without a suspicion arising that extensive bodies of copper or lead sulphides occur at greater depths. Such was indeed the history of Leadville, Colorado, of Bingham, Utah, of Ely, Nevada, and of Mount Morgan (Australia). The last is one of the world's greatest gold mines; yet it is now producing copper from its lower levels; and developments have proved it to be a great copper mine. Immense low-grade deposits of copper ore are found below the gossan at Ely and at Bingham, although it is doubtful whether the most experienced geologist or keenest observer of mineralization phenomena would in either place have felt justified in predicting the existence of the wealth below.

In other localities the metals have either all been removed, or else the primary sulphide ore was too poor in gold to leave oxidized ore of any value. In such cases the discovery of the subterranean treasures is purely fortuitous. Butte may be considered the most conspicuous example of this class. The outcrops of its copper veins contain the merest traces of that metal; and there is seldom enough silver or gold in them to justify mining even under the low costs obtaining here today. The zone of oxidation is generally from 100 to 200 ft. deep; and if it had not been for the presence of another system of veins carrying silver, of different age and origin, but closely associated with the copper lodes, this greatest of copper districts might not yet have been discovered. It was in the search for silver ore that copper ore was discovered here, and one cannot help wondering how many more districts equal to Butte may be undiscovered and unsuspected where no outcropping silver or gold lodes attract the prospector. Here is surely an important and unexplored field for the geologist. The study of oxidized vein phenomena may yield results thoroughly satisfactory from both the material and the scientific point of view.

Below the zone of oxidation the chemical reactions that take place between the descending acid solutions and the unoxidized ores result in the formation of more and richer sulphides, down at least to the level of the lower limit of free circulation, and as far as surface waters penetrate. And as erosion of the surface is continually bringing deeper and deeper sulphides within the reach of oxidizing and dissolving surface waters the operation is in constant progress, and these lower-lying ores become more and more enriched until in some cases bonanzas of almost inestimable value are formed. It is a fact of much significance that bonanzas are generally limited to depths where descending waters may have penetrated at one time or another. Indeed, the very channels through which the enriching solutions came can often be detected, and peculiarities of shape and position observed that can be explained with difficulty on any other theory.

* H. V. Winchell, 'The Synthesis of Chalcocite,' *Bulletin Geological Society of America*, 1903.

Practiced miners often point to the richness of ore-shoots near the junction or crossing of veins. Indeed, such pockets and shoots are usually sought and frequently found where two veins come together. This fact alone may not signify the instrumentality of downward-moving waters. But when in connection with it we discover that rich ore-shoots are also frequently found at the intersection of veins by faults, and zones of movement so recent or of such shallow depth or limited extent that the faults themselves are not veins, and have not been mineralized except near the intersected veins, and when the ore-shoots thus formed occur on that side of the fault-plane where they could have been formed most naturally by descending waters, and are wanting entirely in the corresponding place on the other side, then indeed, we recognize beyond a doubt the agency of meteoric waters in both situations. It is often possible where sulphide ores have been deposited in soluble rocks to distinguish between the products of ascension and descension, and here too the latter are frequently of much the highest grade.

This theory of secondary enrichment, which is so frequently referred to in recent mining literature, and is still so little understood, depends, of course, on the existence of a body of primary ore, probably formed by ascending solutions. If there are no ores to be oxidized, the downward-moving waters will have no metalliferous burden to deposit. But wherever the rocks contain disseminated ore, no matter how small the percentage, there is a possibility of the formation of richer ore through the action of surface waters; and where the primary mineralization was itself comparatively rich, even though not a minable product, there the downward-moving waters may the more readily bring about concentrations of high-grade bonanza ore.

Bearing in mind this conception of the meaning of 'secondary enrichment,' and admitting that it is frequently accomplished through the agency of descending meteoric waters, let us briefly consider the conditions under which they are most active and efficient: It is a proposition requiring no argument that if by the aid of mineral-bearing solutions the ores occurring in veins are to be enriched, these solutions must enter the veins. And if all the meteoric waters that fall upon the outcrop of a vein, or upon rocks containing disseminated ore, run off rapidly down the mountain-side without remaining to oxidize, dissolve, and penetrate the vein with their load of mineral, there cannot be any enrichment caused thereby. Furthermore, if the work of the surface waters is chiefly destructive mechanically instead of chemically, there will be little opportunity for the deposition of secondary concentrations of ores within the rocks. If, for example, the principal effect of the rains and snows is to erode and wash away the exposed portions of veins with all their contained ores, there will be a scattering and wasting instead of an assembling and storing. In other words, secondary enrichment by descending waters depends first of all upon *the ratio of oxidation to erosion*. Where erosion is more rapid than oxidation the unoxidized sulphides will be found in the rocks and veins at the surface of the ground and in the sand rolling down the beds of torrential streams as in Alaska. While, if oxidation precedes erosion, the uppermost zone of a sulphide ore deposit will be oxidized and leached off its base minerals, as is the case here in Butte, and to varying extent over the larger portion of the temperate zones of the earth. Assuming that the conditions are such as to permit the entrance of surface waters, and that the ground-water level is at some depth, which depth naturally varies from year to year and age to age because of many common geological conditions, the factors upon

which depend the extent of secondary enrichment are:

1. Quantity of water.
2. Time.
3. Temperature.
4. The physical structure and solubility of the rock containing the primary ore, and of the ore itself.

It is manifest that a large supply of mineralizing solution will accomplish greater results than a small supply, provided it follows the course of the ore. For the metals in solution can hardly escape precipitation by reaction with the primary sulphides present, sooner or later, at some depth; and the oxidizing and dissolving effects will certainly increase with the amount of active oxygen-bearing moisture available. In regions of slight rainfall there may be partial oxidation to the depth of several hundred feet; and yet there may still remain particles of the primary sulphides upon the very surface of the rocks. Chemical activity is great; but the thirsty rocks quickly absorb that part of the water of rains and melting snows which is not evaporated, and the work of oxidation is not so complete as in regions more plentifully supplied with rain. On the other hand, there may be such heavy and constant downpourings of rain, even in tropical regions, that erosion is again the most active agent.

The second of our factors is Time; a commodity of which the geologist is accustomed to make most liberal and even extravagant use in his arguments and theories. In this he is frequently justified; and the most astonishing results may be produced by the long continued but slow operation of natural forces in any given direction. Events of the past few years have, however, reminded us forcibly that catastrophic phenomena must not be forgotten in comprehensive reviews of the earth's history.

The time element enters in a variety of ways into the problem of ore formation by descending circulations. Thus, an ore deposit formed in its primary low-grade constitution during earlier geological periods, such as the Cambrian or Huronian, and during all of the subsequent ages exposed to the action of superficial agencies unhampered by subsequent covering of later rocks, has a thousand-fold the opportunity for concentration of its ores that is presented by similar rocks and ores formed during later geological epochs, say the Tertiary. This is exemplified by the iron ores of the Mesabi range as contrasted with the glauconitic deposits of New Jersey or Texas. During almost all the ages since the Cambrian the iron ore formation of the Mesabi has been exposed to the weather, covered only for a geological moment during a part of Cretaceous time. The result is the largest and purest deposits of iron ore ever discovered, while rocks of similar composition but much more recent formation exhibit only the initial stages of ore formation.

Another way in which time affects ore deposition is in connection with the rate at which the waters move in a vein. Solutions of a given composition may move so rapidly as to produce but little effect, or may move so slowly that they clog up or retard other active waters after their own power is exhausted. Upon a steep drainage slope or mountain the waters may pass off so rapidly, even below the actual top of the ground, as to exert but little influence, or they may move with just sufficient rapidity to accomplish their maximum of chemical effect.

Our third factor, Temperature, is of great importance. In the first place, oxidation, which is but another name for combustion, is greatly accelerated or retarded by slight changes in temperature. Sulphides that remain immersed for centuries in water under a glacier in Alaska

would be completely oxidized in a few years exposed to the heat of the sun on a southern slope in Colorado or California. In the next place, the rate of solution depends directly upon temperature, increasing as the temperature rises, and, itself a process of heat consumption, is greatly facilitated by heat from external sources. Thus in warm rocks, in mild climates, upon the sunny side of mountains, there will be the most favorable conditions as regards temperature, for the formation of secondarily enriched ore deposits. The experienced prospector will tell you that it is in precisely these localities that they are found; although he never before heard any explanation for it.

Lastly, the physical structure and solubility of the rocks and ores effect their susceptibility to later enrichment for perfectly obvious reasons. A dense rock is not readily entered by mineralizing solutions. Likewise an insoluble one is not easily replaced and does not afford lodgment for ores. And if the ores themselves are not readily attacked by oxidation or by solvents, the quantity, time, and temperature may all be sufficient to accomplish great results with more tractable ores, but have practically no effect upon these refractory ones. A good example of this again is found on the Mesabi range where the heat of an eruptive rock has so altered a portion of the iron formation for many miles that it has resisted surface solution and concentration, and is a worthless low-grade mixture of rock and magnetic ore still; while away from the influence of the eruptive, have been formed the iron ore deposits that have given to the iron and steel industry of this country the raw material required to enable us to control the markets of the world.

Reduced to more simple language and ideas the foregoing remarks amount to a statement that climate, sun, rain, average temperature, topography, depth of soil or surface, debris, erosion, glaciation, and other common and often unobserved influences and conditions have decided bearing upon the important question of ore formation.

These are the phases of our modern theory that have received little attention hitherto; and are yet of a practical value that can hardly be overestimated. We find few bonanzas of high-grade ore in Siberia, Russia, Alaska, British Columbia, Washington, or northern Ontario. Our theory tells us why they are not to be expected, and why such enriched ores as are found seldom extend downward to great depths. We turn to regions of milder climate, less glaciation, gentler topography, and we find the rocks altered and softened and oxidized to some depth below the surface. We find that the veins wear 'iron hats'; and beneath them we find bonanzas reaching to great depths. We find our best ore-shoots on the sunny sides of the mountains, while the veins on the northern or shaded sides, where the snow lies till mid-summer and the rocks are cold, produce no such rich ore. We begin to realize that our theory is based on fact and proved by observation; and that it justifies us in placing confidence in it, and in acting upon it within reasonable limits. And we marvel that facts so simple and of such easy comprehension and yet of such practical value should receive so little attention from the writers on ore deposits.

LOW-GRADE IRON ORES.—Someone in Christiania, Norway, has invented a system of treating low-grade iron ores in an electric smelter, with graphite as a reducing medium instead of coal, and he has been awarded a prize for the invention by the Iron & Steel Institute. There are large quantities of graphite and of low-grade ores in Norway, and the existence of water-power makes the invention a valuable one if it can be worked on a large scale.

The Leadville Downtown District.

High up among the peaks of the Front range of the Rocky Mountains in Colorado, more than 10,000 ft. above the sea, in a terraced basin at the very head of the great Arkansas river, stands the city of Leadville, covering with its rectangular system of streets and contiguous smelting works an area of over 500 acres. On the hill-slopes back of the city are the mines, which since 1860 have year by year added immense amounts to the world's metallic wealth. In the early eighties it was estimated that this district's annual product of silver alone exceeded that of any silver-producing country in the world except Mexico, while its lead product nearly equalled that of England and was surpassed only by that of Spain and that of Germany—all mined from an area not over a square mile in extent. Today—more than twenty years later—the Leadville district is still a marvel in its metallic production. In 1906 its mineral product, overpassing all its own previous records as well as those of every other mining district in Colorado, amounted to nearly a million tons of ore. Zinc, silver, lead, gold, and copper, in the order named, to the value of over \$15,000,000, were dug from these treasure-holding hills, whose store of mineral wealth is still apparently inexhaustible. It is a notable fact that zinc, once despised by the miners, now leads in value.

The history of the discovery and development of the Leadville ores has been told many times, but its interest may justify a brief statement. Gold was discovered in California gulch on April 26, 1860, and the news spread with amazing rapidity, notwithstanding the difficulties of communication in this wild and inaccessible region. In three months over 10,000 persons were in the camp, and it is said that over \$2,000,000 were taken out during the first summer. The climax was soon reached, however, and within three or four years the population was counted by hundreds instead of thousands. In 1874 the now famous carbonate deposits were discovered. The first smelting furnace was erected in 1877, and the subsequent growth of the city has kept pace with the development of the region. The most notable recent undertaking in the district is the wonderful Yak tunnel, probably the greatest mining enterprise in the United States. The works already comprise a main adit from which extend miles of laterals, provided with electric lights and telephones and equipped to handle 1,000 tons of ore per day.

Early in 1880 the United States Geological Survey, then but a year old, sent to Leadville a party of geologists and topographers, headed by S. F. Emmons, to study and map the district. A preliminary report of this investigation was published in 1882 and an extended report was issued four years later.

At the close of the Survey field work in 1881 underground exploration was practically confined to a zone about 1,000 ft. wide along the eastern or upper edge of the camp. Within recent years mining operations have been carried westward under the city into what is called the Downtown district, and revised and extended maps of the whole district, showing underground workings, are now being prepared for publication. In advance of this publication a description of the Downtown district, accompanied by maps and sections, has been issued by the Survey as Bulletin No. 320. The data for this bulletin were obtained principally by personal explorations made by its authors, S. F. Emmons, the writer of the original reports, and J. D. Irving. This preliminary report is published now partly because the information is needed for immediate use by those engaged in mining in Leadville, partly because it is hoped that it will bring out criticisms which will be available in time to correct any errors before the publication of the new general map.

Silver-Lead Smelting Practice.—V.

By T. S. AUSTIN.

Edited for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

***ROASTING.**—My observation has been that roasting is left very much to chance in large plants, and the reverberatory has been retained only because its defects are the cause of its good work, that defect being the absence of all mechanical assistance in handling the ore. My opinion of the Bruckner cylinder is that it requires very close watching and careful management, and this it does not get under ordinary circumstances and in plants of large size, where the superintendent cannot give close supervision to all details. I do not think the Grant works made their success metallurgically by their reverberatory roasting furnaces. They probably made it by handling roasting ores, and had to have a large roasting plant to do it. Of course, it is better to mix roasting ores so as to have a combination that will be constant in composition, and, if you receive various kinds of ore, you can do this. Pyrite helps in the roasting of both arsenic and blende ores; lead tends to agglomerate the charge, silica to decompose the sulphates.

FURNACE GASES.—When working with good reduction on the slag (with the lead under 1%) I have got 14 to 16% CO₂ and 8% CO, by volume. My experiments were more extended at Monterrey, and I had wide ranges in my results. Often the CO was nearly equal to the CO₂, there being 12 to 14% each. I have seen cases where the CO₂ was 20% and the CO only 6%, but this was rare, and I do not recall how the other conditions of the furnace were. I am inclined to think that the ratio of two CO₂ to one CO is about the point of good reduction.

SUCCESSFUL RUNNING OF SILVER-LEAD BLAST-FURNACES.—[Speaking of a patented fore-hearth, which had been successful on a basic slag, he predicted its failure where used for stiff blende slags, or for silicious limy ones, in fact, for conditions under which customs smelters have to run. He judged, from conversations, that the inventor was more practical than theoretical, and not very practical either, in handling ores of different kinds. Leadville smelting had made many men think they are metallurgists who had no claim to the title. Farther he adds:] I still pay a great deal of attention to the furnace running, for it is there that success depends. [He repeated this to me in 1902.] A foreman can handle men, even manage to keep the furnace in good condition but he cannot smelt. His knowledge is not enough to grasp the whole situation. Only a superintendent or metallurgist can do this, as he knows all the conditions that are entering into the problem. If I had it so that I could run with large batches and few charges, I could bring losses down to about *nil*. As it is, I can reduce them to 2% of the silver and 5% of the lead. My silvers rarely get over two ounces on the highest bullion I can make. I am now making on one furnace a half-slag, Pb 0.6 to 0.8%, Ag 0.6 to 0.8 oz. per ton, producing 180 to 200 oz. base bullion [this was before the day of large fore-hearths], using 13% of Trinidad coke and 2.5% charcoal. I run my regular three-quarter slag on the other furnaces, using between 17 and 18% fuel on the 12 by

120-in. furnace. My slags run, if of this type, about 0.5 oz. Ag for every 100 oz. contained in the base bullion.

SILVER-LEAD SMELTING AT EL PASO.—The system of getting Mexican ores part in bond, part free, with American free ores precludes the possibility of large mixes, as these different kinds of ore must be kept separate. This entails an immense amount of labor in handling, as well as great confusion at scales and elevators, frequent changes of charges, and a lot of minor inconveniences. The bad draft of the big stack and flue system (in 1897) makes it hard to regulate feeding, as the smoke passes out as soon as the door is opened. The furnaces, except one recently designed and put in by Mr. A. S. Dwight, are antiquated and ill-designed for good reduction. The ore is coarse, and it is hard to pack the furnaces. Still I have knocked 10 to 15% out of the mattes and largely reduced their silver tenor from what it was. With good conditions of furnaces, there is no reason why better work cannot be done. At any rate I hope to greatly better it. I am using a good deal of scrap iron—10 to 20 lb. per charge—as an assister of reduction. Slags are clean enough, but the mattes are strangely high. I have never, anywhere, had trouble in making 10 to 12% lead-mattes; here they are good at 20 per cent.

[Six months later than when these observations were made, he was able to say:] Matters are going nicely here. In fact, it is quite the custom for them to go so, even with our old-style furnaces. There is a variety of conditions, however, even in the months themselves. However, the work metallurgically shows a much greater evenness than it formerly did when I commenced, owing to a better understanding of the ores. Our work (in roasting) is often unsatisfactory, owing to varying conditions of both ore and matte. Arsenic is troublesome, and the granulated matte (no matter how low in lead) is hard to roast, as it develops a great tendency to agglomerate.

METAMORPHISM OF COAL.—At a small town called La Brea, in Sonora, Mexico, situated about 65 miles southeast of Torres on the Sonora branch of the Northern Pacific from Nogales to Guaymas, there is anthracite coal and natural coke. On looking over the outcrop, the only indication of coal is a gray clay, which on closer inspection proves to be ashes from burnt coal; below these ashes comes the natural coke, heavy in ash, although it will burn with a forced draft. Some of the veins are 10 ft. thick and extend down to nearly 100 ft.; beneath the coke is anthracite coal of fine quality as far as analysis goes, but it slacks on exposure to the air. Apparently the coal measures were ruptured by a volcanic eruption, and the molten rock, on reaching the outcrop of the coal vein, burnt the coal to an ash where it had plenty of oxygen; when it did not have oxygen, it had the same effect as if placed in a coal-kiln. The pressure and heat changed the coal from bituminous to anthracite. Situated in this coal-field is the shaft of the old Tamorarra copper and silver mine, 500 ft. deep in the eruptive rocks covering the coal measures. The copper and silver vein penetrates this eruptive, and on sinking the shaft, they encountered one of the coal seams, the coal being used in boilers for roasting, etc., in a chlorination plant.

*These observations of T. S. Austin, recently deceased, general superintendent of the Southern Department of the American Smelting & Refining Co., are compiled from letters written by him to his brother, from 1883 to 1906, covering most of the period of his wide experience in silver-lead smelting, and to some extent that in base-bullion refining. They lack some of his recent experience, but show that much of his knowledge had been brought into finished form some time before his death. The notes refer largely to his work at El Paso, New Mexico, Monterrey and Chihuahua, Mexico, and to El Paso, Texas, together with other technical observations made during that time. Professor L. S. Austin's remarks are in brackets. The first of this series appeared in our issues of February 23, March 16, April 27, and June 15.

The wages of the coal miners of England and Wales was increased by 5 per cent from the first of May. This applies to all underground labor and to the wages of surface labor engaged on the pit banks and screens in manipulating the coal. This will be the second advance of 5 per cent this year, the previous one going into effect on the first making-up day in January.

The Prospector.

Enquiries sent to this department are answered free of charge. If submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

A fragment of Gabbro was sent from Sheridan, Mont., by H. G. D.

Four specimens of Dacite were sent by O. U. B. from Wonder, Nevada.

P. H. B. sent a specimen of specular Hematite from Wickenburg, Arizona.

The rock sent by E. P. D., from Rosa Morada, Mexico, is an altered Andesite.

The specimens sent by J. A. P. from Fairview, Nev., have not been received.

A specimen of Chalcedony, lined with drusy quartz, was sent from Michigan Bluff, Cal., by J. A. S.

The mineral Hübnerite, which is a tungstate of manganese, was sent from Pioche, Nev., by J. W. A.

The rocks sent by H. G. G., of Wonder, Nev., are: No. 3, Dacite; No. 4, Dacite; No. 5, Dacite; No. 6, Rhyolite; No. 7, Dacite.

The rock specimens sent from Seven Troughs, Nevada, by F. D. B. are: No. 1, Rhyolite; No. 2, Rhyolite; No. 3, Rhyolite Tuff; No. 4, Dacite; No. 5, Basalt; No. 6, Dacite.

B. R., of Hawthorne, Nev., sends: No. 1, Calcite and Siderite; No. 2, Grossularite and Quartz; No. 3, Quartz; No. 4, Basalt; No. 5, Basalt; No. 6, Basalt; No. 7, Basalt; No. 8, Rhyolite; No. 9, Rhyolite; No. 10, Andesite.

Making an Artesian Well Pump Itself.

The field men of the United States Geological Survey, in their investigations of the ground-water resources of the Virginia coastal plain, have observed that the flows from many artesian wells in that neighborhood are utilized to drive hydraulic rams for the purpose of lifting water to the higher levels. Along the lower courses of the Potomac and Rappahannock and along the shores of the many inlets that run back from Chesapeake bay above the James, there are hundreds of artesian wells that supply a perennial flow of beautifully clear water which is, as a rule, excellently adapted to all domestic uses and is largely utilized by the canning factories and other industrial establishments that abound in that part of the country. Though the pressure of the water from the wells is ample at the shore level, the head diminishes so quickly with increase in elevation that no flow can be obtained along the higher banks above the shores, where the water is most needed. The common method of obtaining it at these higher levels is to use the force developed by the artesian flow to operate hydraulic rams, which in turn raise the water to the heights desired along the bluffs above the rivers and inlets. Thus it may be said that the artesian wells pump themselves.

SOUTH WALES COAL, according to report, is no longer being purchased largely in the Cape Colony in South Africa, as Natal coal is taking its place, due to the preferential treatment of the Natal product.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

Under the statute of Colorado a person who flowed water from his mine into a natural stream with the intention of appropriating it for irrigation purposes, and he did actually make the first appropriation thereof, was entitled to such water as a first appropriator.

Ripley v. Park Center Land &c. Co. (Colo.), 90 Pac. 75. (May '07.)

Where no place was specified for the payment of royalties in a coal lease, they must be demanded on the premises before there can be any forfeiture for the non-payment.

Drake v. Penn. Coal Co. (Pa.), 66 Atl. 660. (April '07.)

An agent appointed to care for mining property and its title for a corporation of which he was a stockholder, and to accept service of process, but was given no funds to pay taxes or other expenses, and was without authority to advance money for the corporation after repeated notices by him to such owner that taxes were due, that the property had been advertised for sale at tax sale, was held to have the right to bid in a part of the property after most of it had been sold for taxes, and thereafter obtained a tax deed and thereupon notified the corporation, offering to convey if it would reimburse him, and subsequently sold the property which was then wholly unproductive. The original owner was held not entitled to recover the property six years later after valuable ore had been discovered.

Steinbeck v. Bon Homme Co., 152 Fed. 333. (March, '07.)

The owner of the mineral estate may by contract with the owner of the surface relieve himself from the duty of supporting the surface, and from all liability for any injury done to it by mining and removing the minerals from the mine below.

Miles v. Penn. Coal Co. (Pa.), 66 Atl. 764. (April, '07.)

A miner, while attempting to remove a car which had been stopped by reason of a defect in the track, was run into and injured by another car which the foreman of the mine was pushing along the same track. It was held that the defect in the track was the proximate cause of the injury and not the act of the foreman, and that the mine owner could not escape liability on the ground that the accident was so remote a consequence of the defect as not to be expected with any degree of reason.

Moore v. Royal Lead &c. Co. (Kans. App.), 102 S. W. 616. (May, '07.)

Under the Illinois statute the operator of a coal mine is required to provide miners with a sufficient supply of props, caps, and timber on demand, and this duty is not discharged by the operator furnishing such props, etc., as he himself deems sufficient, but he must furnish any particular kind on a reasonable and timely demand by a miner.

Springfield Co. v. Gedutis (Ill.), 81 N. E. 9. (April, '07.)

In an action for the death of a miner caused by the falling of the roof of the mine where he was working, and based on the failure of the operator of the mine to furnish proper supports, it was held that a witness who went to the place just after the accident could testify as to what crossbars there were in the room.

Springfield Co. v. Gedutis (Ill.), 81 N. E. 9. (April, '07.)

A miner who went from his usual place of work in the mine to another part of the mine to get some tools he had formerly loaned to another employee, assumed the risk incident to the place to which he went, and was not entitled to recover for injuries occasioned by the falling of slate from the roof of that part of the mine.

Pioneer Min. &c. Co. v. Talley (Ala.), 43 So. 800. (May, '07.)

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

CRUSHING AND GRINDING MILL.—No. 857,121; Thomas L. Sturtevant, Quincy, and Thomas J. Sturtevant, Wellesley, Mass., assignors to Sturtevant Mill Co., Portland, Me., a corporation of Maine.

In a vertical crushing and grinding mill, the combination with a suitable base, of a vertical post or standard, a casing comprising two parts which are vertically hinged to said post or standard and which rest on and are secured to said base when in closed or working position, said casing parts being formed independent of said post or standard and being thus adapted to be loosened or swung aside horizontally and simultaneously to relieve clogging of the mill or when access to the chamber of the mill is desired, normally stationary or non-rotary crushing elements mounted on said hinged casing parts, a vertical shaft within said casing, and rotating crushing elements mounted on said shaft and which may be removed from said shaft, without taking the latter out of the mill, when said casing parts are swung aside.

BLAST-FURNACE CHARGING APPARATUS.—No. 857,259; Charles H. Sample, Homestead, Pa., assignor to Walter Kennedy, Bellevue, Pennsylvania.

A blast-furnace charging apparatus having in combination a main hopper and bell, a bell at the upper end of the main hopper, a movable shell above and movable around the axis of the upper bell and provided with an eccentric discharge opening, and means for shifting said shell.

DREDGE-BUCKET.—No. 857,396; Isaac B. Hammond, Portland, Oregon.

In a dredge, the combination with a traveling bucket formed with an outwardly-flaring surrounding wall, of a bodily-movable, bucket-contents loosening, plunger in the base-portion of the bucket surrounded by said wall, an actuating lever for the plunger carried by the bucket, and a shoulder in the path of travel of the lever.

ORE PULVERIZER AND CONCENTRATOR.—No. 850,952; Obadiah K. McCutcheon, Pittsburg, Pennsylvania.

In a pulverizer and concentrator, a suitable receptacle designed to receive water and ore, a cylinder journaled longitudinally of the receptacle, means for rotating the cylinder; the said cylinder having a series of diagonally-disposed openings therethrough, bolts in said openings having flattened heads extending longitudinally thereof and provided with apertures, means for securing the bolts in place, beaters applied to the bolt-heads, said beaters consisting of blades having bifurcated inner ends to receive the heads of the bolts, and having transversely-disposed apertures adapted to register with the apertures of the bolts, and securing means engaging the bolts and beaters.

MECHANICAL DRIER.—No. 857,161; William M. Cummer, Cleveland, Ohio.

As a new article of manufacture, a drying cylinder formed in sections, and rings connecting the sections provided with openings transversely through the middle thereof, whereby draft passages are formed into the cylinder.

Spiral Feed for Tube-Mills.

The Editor :

Sir—Referring to your issue of April 27, on page 541, we notice an article entitled 'Feeder for Tube-Mill.' As you are probably aware, we have been developing and perfecting the spiral feed and discharge for the past five years and have had its application to tube-mills patented in a variety of styles in the United States and foreign countries. Among our patents is one on which the feed shown in your paper is without doubt an infringement, although we harbor no ill feeling against the parties describing or using it. The writers of the article mentioned we believe are, or were, connected with a company to whom the advantage of our feed was fully explained several years ago, but who did not favor us with their order, as they were rather skeptical regarding our claims. Now, although we are no doubt in a position to bring action against these people for infringing our patents, we think that in view of the fact of their endorsing our feed so highly, we shall not do so, as their expenses for wear and tear on the mill as furnished them

originally were no doubt very high and then they had in addition to pay the cost of rebuilding the machine. In justice to ourselves, however, we think it no more than right that you give this letter the same prominence that the previous article had.

We forward herewith an illustration of our Ideal spiral feed, showing that we formerly made it of wrought-iron plate, protected by cast-iron heads. Our latest construction is to make it entirely of cast iron.

The inventing of this spiral feed was the means of perfecting the tube-mill. Heretofore, there was no feed on the market that did not require both a separate driving arrangement and stuffing-boxes to stop it from leaking, whose main working part was a conveyor, which frequently wore out, got clogged up or broke, causing long and serious delays.

The foregoing troubles have been overcome by the simple arrangement described, which does away with a special drive, being attached direct to the mill, with which it revolves. The saving in labor will be readily appreciated when it is considered that a 4 ft. 6 in. by 20 ft. tube-mill has a charge of eight tons of pebbles and a 5 by 22 ft. mill a charge of 10 tons.

There are several more important advantages gained by the use of our Ideal spiral feed and discharge, which apply to trunnion as well as tire machines. First: It allows the loading of pebbles from 5 to 8 in. over the centre, which is not possible with machines that are equipped with other feeds, as the pebbles would clog them up or break them entirely, thus giving our mills an increased grinding capacity. Second: The pebbles in all tube-mills, when in operation, are carried up on the side toward which the machine revolves, so that a certain quantity of those on the bottom, on one side of a line drawn from the centre of a mill, are balanced by those on the other side of this line, and the weight to be lifted is thereby greatly reduced. In our tube-mills, where the charge of pebbles extends over the centre, the balanced portion is proportionately increased, thus greatly decreasing the power required to operate them.

When reducing material wet, another advantage, in addition to those above stated, is gained. With our feed these mills can be pumped from two-thirds to three-fourths full of material, by attaching a valve at the discharge end to regulate the outflowing stream, by which the grinding capacity is nearly doubled and at the same time the power

is reduced about 40%, so that a 5 by 22 ft. mill (tire style) can be operated with the use of about 40 horse-power.

You will readily appreciate that the engineers who designed the feed for the tube-mill, mentioned in the first part of this letter, unwittingly paid us a high compliment by so closely imitating our design.

ABBÉ ENGINEERING CO.,

Paul O. Abbé, Secretary.

New York, June 20.

Ejectors as Liquid Elevators.

There is a little machine known as an ejector, whose large field of usefulness is not yet appreciated by a great many users of steam. It is marvelously simple in construction, requires but a small amount of steam—far less than a steam pump—and on account of its compactness and portability, allowing it to be placed with little expense near the work to be done, is becoming a common substitute for steam pumps, syphons, etc. It would be difficult to enumerate all the uses to which an ejector is adapted, but when we say that anything and everything in the nature of a liquid (if not too thick) can be transported from one level to another, or horizontally any reasonable distance, the ground is just about covered.

Complete information as to the XL-96 ejector and its uses may be obtained by writing to the manufacturers, Penberthy Injector Co., at Detroit, Michigan.

Commercial Paragraphs.

THE WIRT ELECTRIC CO., of Philadelphia, has been absorbed by the Cutter-Hammer Mfg. Co., of Milwaukee, Wisconsin.

THE ALLIS-CHALMERS CO.'s office at Seattle, which is in the charge of G. W. Pulver, the district manager, has been moved to No. 115 Jackson street.

THE KROGH MANUFACTURING CO. is again back in the same site as before the earthquake and fire. The new address is 149 to 163 Beale St., San Francisco.

THE NATIONAL WOOD PIPE CO. announces that owing to the unprecedented growth of its business and the establishment of the general offices of this company at Los Angeles, necessitating additional space for its officials, engineering corps, and clerical staff, it has secured the commodious rooms 403 to 409 Equitable Savings Bank Bldg., on First and Spring St., and now occupies these new offices.

Trade Treatises.

THE LUNKENHEIMER CO., of Cincinnati, Ohio, has issued a booklet called 'Generator Valves,' for use as check-valves on two-cycle engines.

THE D'OLIER ENGINEERING CO., of Philadelphia, is sending out a new Bulletin—Series T, No. 8, on 'Centrifugal and Turbine Pumps.'

ROCKWELL ENGINEERING CO., of New York, sends an illustrated description of their rod-heating furnace and of a similar furnace for heating bolts.

THE NEW YORK FLEXIBLE METALLIC HOSE & TUBING CO., of New York City, has issued Bulletin No. 25, on Hyflexmet lead-covered flexible metallic hose and tubing.

AMERICAN SPIRAL PIPE WORKS issues an excerpt from their catalogue of forged steel pipe flanges. This catalogue is a most complete work and ought to be valuable to engineers.

THE UTAH MINING MACHINERY AND SUPPLY CO., of Salt Lake, mails us Bulletin No. 400, describing the Callow settling and pulp-thickening tank, and the Callow system of ore classification.

THE AMERICAN SPIRAL PIPE WORKS, of Chicago, Ill., sends us an attractive 100-page catalogue of 'Forged and Rolled Steel Pipe Flanges,' including special forgings, and full-sized cross-sections of flanges used in the different standards.

Editorial.

ACCORDING TO a special report issued by the statistician of the Census, it appears that California, with a population of less than 1,500,000, has a total wealth of \$1,200,000,000. To give meaning to these figures it may be stated that France, with a population of 38,000,000, has a total wealth about ten times as much, and Germany, with 52,000,000, is only nine times as rich. The wealth per capita is \$1,125 in the United States as a whole, \$1,155 in Great Britain, \$1,228 in France, \$751 in Germany, \$1,247 in Australia, and \$2,800 in California.

IT IS LIKELY that the 'Notes on Smoke Suits' will interest those concerned with smelting. The writer of that article is, as his observations indicate, an experienced metallurgist, with a wide knowledge of smoke litigation. The subject is vital to the progress of the mining industry, and it is well that it should be discussed frankly, to the end that smelting operations may not be hindered by ignorance on the one hand or carelessness on the other.

ACCURATE DESCRIPTIONS of local geology are apt to be useful to mining engineers. The article by Mr. John A. Reid is a conscientious and clear statement of the conditions under which lead and silver ores are found in the Inyo range, which lies just east of the Sierra Nevada. Mr. Reid's sketches help his description, and the article as a whole affords a good example for the younger men to whom opportunities for similar observations must often be presented in the course of their work as mineral scouts.

EVEN the honored name of Abraham Lincoln is used as a lure by peddlers of mining stock. The portrait of the great patriot is employed to adorn the offer of shares at five cents made by a "financial agent" at Chicago. To put the name of Lincoln on the lure of a promoter indicates a callous effrontery only too characteristic of the vendor of wild-cats. It is to be hoped that the impertinence will warn those who might not otherwise appreciate the misleading nature of the statements made concerning the mine.

PEDDLERS OF STOCKS occasionally make the mistake of sending us their flamboyant circulars. Thus the Knickerbocker Syndicate of New York offers us the chance to buy a stock that is to pay 100 per cent, it being explained that dividends of 100% "are not uncommon in the case of concerns controlling great natural resources." We have no reason to believe that the marble quarries of the Colorado-Yule Marble Company are among the great natural resources that will serve as the basis for such marvelous finance, but we do

think it high time for C. F. Brackett, professor in Princeton University, to consider whether it is seemly for him to be a director of this company. The promoters of it have been inundating the country with their pestilential letters and circulars for more than a year.

WE PUBLISH a letter from Pioche, Nevada, one of the old mining camps that has been revived by the warm air of speculative activity. Pioche was a great district in years that are past and it ought to gain largely by the better facilities to be provided by railroad communication, improved metallurgical methods, and more businesslike ways of operation—that is, provided there is the ore required for the application of these factors. We understand that there is a good deal of low-grade ore in the old mines; this will be determined by unwatering the workings.

Ore Deposition.

IT WAS A SUGGESTIVE IDEA that Mr. Horace V. Winchell offered in our last issue concerning the ratio of oxidation to erosion. He pointed out that secondary enrichments of ore are rare in Alaska, Siberia, and other cold climates while they are frequent in the deserts of Nevada and Australia, or on the sunny slopes of mountains in Colorado and California. It is suggested by him that the higher temperature accelerates oxidation, facilitates solution, and sets in motion the chemical reactions that cause the formation of bonanzas underneath the gossan. In Nevada oxidation keeps ahead of erosion; in Alaska oxidation is slow while erosion is apt to be rapid, more especially within the range of glacial action. Secondary enrichments of copper ore have been found in Alaska at the surface, with the poor primary ore a few feet underneath, as if erosion had removed the overlying portion of the lode at the expense of which the rich ore had been formed, so that instead of an iron hat the lode wears a copper crown, likely to prove misleading to an optimistic novice. We may add that in the hot desert regions of Queensland and Arizona, for example, it is not unusual to find oxidation reaching to 400 or 500 feet below the present surface, indicating the slowness of erosion and the penetrative power of the descending oxidizing waters. Under such conditions silver veins are robbed at their outcrop with re-deposition of the chloride, while gold lodes undergo a chemical and physical concentration resulting in superficial bonanzas of extraordinary richness.

In another contribution on this subject, appearing in the Transactions of the American Institute of Mining Engineers, Mr. George J. Bancroft has offered a scholarly discussion on the enrichment of veins. Many of the conclusions reached by him are re-statements of the views of earlier writers, but they are made from a different standpoint, and in addition to these he offers several new suggestions likely to provoke thought and observation. We are glad to note his references to the ground-water. Geologists have gone astray in assuming a water-saturated zone extending several miles underground, but

mining operations have demonstrated that the rocks become dry in depth, indeed, most deep shafts in the country rock become dusty, because the evaporation is more rapid than the capillary movement of the moisture. Mr. Bancroft writes clearly on this matter, and emphasizes the fact that "the torpidity of the ground-water in depth is caused by the tightness of the rocks." He argues that the position of the zone of flowage, that is, the horizon at which rock deformation is caused by pressure, is not fixed, so that a channel for solutions may exist for a short time below the limit usually estimated, and serve as a passage for ore-forming agencies. In mine workings the ground will swell, and the excavation tends to become closed, but this tendency is a function of time. Next, he offers evidence in support of the view that orebodies are formed quickly by strong solutions. He asks no blank check on the bank of Time. The fact that few, if any, mineral springs have been detected "in the act" of making ore deposits leads him to assert that a relatively short period of time is involved, for otherwise we should be able to see the process in action somewhere. Thus he comes to the theory that the solutions forming orebodies have had rich sources, and that there is a barysphere containing large amounts of the useful metals. All of which is interesting and to the point.

It is likely enough that the weak solution acting for an indefinite period has been given too much credit and that we have avoided the heart of the problem by big generalizations of a perfectly safe kind leading nowhere in particular. But as regards ore deposition "in the act," we have it in Butte where zinc sulphate is deposited on the timbers and copper sulphate is reduced by the iron rails; we have it in the wood that has been silicified and enriched with gold in the alluvial diggings at Ballarat; and we have it in the pick handle that caused galena to be precipitated in a New Mexican mine. In a recent letter from Mr. E. R. Pembroke we are informed of another good example: At Bingham a shaft was sunk by Col. Wall near the entrance to the Yampa mine; the shaft was 40 feet from the creek and also 40 feet deep. At the bottom, which was 7 feet below the bed of the creek, the ground was a loose mass of angular debris. Many of the fragments were coated with metallic copper and cuprite, due to the reduction of copper sulphate by organic matter in the drift. Such instances do not controvert Mr. Bancroft's claim that no mineral springs have been caught in the act of making ore, but it is not necessary that mineral solutions should be emitted in the form of springs; on the contrary, it is our opinion that in most cases the ascending waters lose themselves when they strike the zone of ground-water and that ore formation rarely occurs at the immediate surface. It is erosion that uncovers the seat of action and causes the ore itself to appear as an outcrop.

That ore formation does not need indefinite time is suggested by the comparative youth, geologically, of most orebodies. The number of post-Cretaceous occurrences of ore vastly exceeds those of earlier periods and even in cases such as the Homestake lode, which existed

in pre-Cambrian time, it is likely that enrichment is largely due to later thermal activity associated with the eruptive that breaks through the Cretaceous and therefore is of Tertiary age. The number of veins of ore existing at 100 feet is vastly greater than the number of those existing at 2,000 feet; there is a decrease in the fissuring and there is a still more marked diminution in the richness of the ore occurring in the fissures or associated with them. This indicates a connection with the surface and as the surface is geologically a thing of yesterday, there is the suggestion that the orebodies were not formed at a greatly remote period but are to be credited to agencies that are at work on the outer rim of the earth, although derived from the deep at such times as readjustment of the exterior caused a temporary and local communication with the region underneath.

Electrical Smelting of Iron Ore.

IN THIS JOURNAL under date of November 17, 1906, there appeared an article by Mr. Donald F. Campbell on the iron deposits lying on a ridge dividing the Pitt and McCloud rivers in Shasta county, California, and mention was also made of an experiment on a working scale to be made with the electrical smelting of this ore by the Héroult process. On another page an account of this experiment is given by Mr. R. L. Phelps. A few additional facts, gathered during a brief visit to the locality, may be offered here.

The deposit of iron ore consists of a large body of magnetite, uniform in texture and analysis, containing from 68 to 70 per cent iron, that is, only $2\frac{1}{2}$ to 4 per cent of impurity. Although as yet only partially explored, there is evidence to warrant the expectation of a plentiful supply of ore and it is so situated as to be conveniently transported to the smelter. The magnetite appears to be associated with diorite and it lies at the contact with a limestone so pure as to serve as a flux in smelting. The iron mine and the limestone quarry are alongside. The ore probably originated from a mixture of pyrrhotite and marcasite; it is almost free from sulphur and no sulphides are visible in the ore except in spots along the contact where traces of pyrite can be detected. In brief, the material is particularly well adapted for the purpose in view. It is expected that the ore can be delivered for \$1.50 per ton to the smelter.

Next comes the question of electricity. This is obtained from one of the transmission lines of the Northern California Power Company, whose generating stations are situated in the Sierra Nevada, about thirty miles away. The cost of electric energy is \$12 per horse-power per annum, a figure that leaves a reasonable profit to the power company. The application of electrical smelting to the reduction of this magnetite was the idea of Mr. H. H. Noble, the president of the power company mentioned, and the cost of it is being defrayed by him personally. He had heard of the experiments made at the Sault Ste. Marie under the auspices of the Canadian government and entered into communication with Dr. Paul Héroult, the inventor of the electrical furnace.

It will be remembered that at the Sault the Sudbury ore was converted into nickel-steel at the works of the Lake Superior Corporation, but the result was a failure from a commercial standpoint because the product brought only \$35 per ton as against the \$65 that was expected. The nickel trust (the International Nickel Company) controlled the market too effectively, so the Canadian government abandoned the experiment. It was on a small scale, and largely inconclusive, although encouraging. Then experiments were made at Portland, during the time of the Exposition. These were misleading and badly conducted. In the meanwhile the making of steel from iron in the electrical furnace had become an established process and the success of this method was often confused with the much more important and basic process of smelting the ore itself. Moreover the earlier experiments had involved the use of a single-phase current and here in Shasta county the current available is of the three-phase type. It was feared that the three electrodes in the furnace would short-circuit so that the current would not pass through the neutral pole, that is, the bottom of the furnace, which is made of a carbon paste, tamped tight, and of the same material as the electrodes themselves. Such fears have proved groundless, for the furnace works most satisfactorily in this regard; the perfectly even tone of the humming noise made by the operation suggests the steadiness of the current, as is confirmed by the ammeter. For a description of the furnace the reader is referred to the article by Mr. Phelps. Several interruptions were caused, one being due to a pump, another to clogging of a charging tube, and just as this was being corrected the power line was broken by careless blasting on the right-of-way of a new branch railroad now under construction from Pitt to Bully Hill. This shut off the current and stopped the smelting, at the moment when the iron was about to be tapped. Some of it was actually obtained and of good quality. As soon as repairs to the wires are completed, smelting will be resumed by turning on the current and melting the frozen charge just as it is. A 'freeze-up' does not matter in an electrical furnace.

We hope shortly to be able to give further information. The experiment is being conducted in the presence of Dr. Héroult himself and several other metallurgists of established reputation. It means much to California, for the best pig iron sells in San Francisco at from \$30 to \$32 per ton. At Pittsburg it is worth \$20 to \$23. That used in this State comes by sea from Europe, mainly as ballast, and pays a heavy duty. Hence the high price. No iron is made in California, mainly because a suitable cheap fuel is lacking. It is estimated that the magnetite in Shasta county can be converted into pig iron and placed in San Francisco for \$15 to \$18 per ton. If this expectation is fulfilled the industrial development of the Pacific Coast will receive a great stimulus and Mr. H. H. Noble will deserve to be hailed as a pioneer and benefactor.

As we go to press we learn by telephone from the smelter (280 miles from this city) that five tons of iron have been tapped, that the quality of it is excellent, and that successful results are confidently anticipated.

Personal.

J. R. FINLAY is at Joplin.
CURTIS H. LINDLEY is at Salt Lake.
H. C. HOOVER is expected at London.
P. B. WAUGH has returned to London from Bolivia.
WILLIAM BRADEN has arrived at New York from Chile.
J. H. CURLE sailed from New York to London on July 16.
O. B. PERRY is in the Cariboo district, British Columbia.
RICHARD A. PARKER has been examining mines in Nevada.
LEWIS T. WRIGHT is on his way back from London to San Francisco.

AUGUSTINE LAWRENCE has gone from San Francisco to El Oro, Mexico.

D. M. RIORDAN is at the Bully Hill mine, in Shasta county, California.

H. P. GARTHWAITE has returned to the Butters Salvador mines, in Salvador.

WILLIAM FORSTNER is examining copper deposits in Inyo county, California.

G. E. ALEXANDER, formerly at Denver, is in charge of mines at Sparta, Oregon.

T. RUST has returned to San Francisco from the Cœur d'Alene district of Idaho.

E. J. BAYLISS and C. V. HAINES have opened an office at 683 Salisbury House, London.

RICHARD M. ATWATER, JR., has returned from an extended professional trip in South America.

FRANK DOREMUS, of Santa Barbara, is with the Mammoth Copper Co., at Kennett, in California.

NOEL BARBER, recently with the Combination Mines Co. at Goldfield, has gone to El Oro, Mexico.

W. C. HAMMATT, constructing engineer, has finished his work for the Mammoth Copper Co. and is now in this City.

THOS. A. VARDEN has been at Kennett, in Shasta county, Cal., this week, making an examination of the Uncle Sam mine.

JOHN E. ROTHWELL is at Indé, in Durango, where he is building a cyanide plant furnished by the Colorado Iron Works.

LLOYD WOMBLE, of the Witwatersrand Deep mine, has reached San Francisco from South Africa on a six months furlough.

D. A. LYONS, professor of metallurgy in Stanford University, is visiting the mines and smelters of Shasta county, California.

W. E. SIMPSON, formerly at Kalgoorlie, has become consulting engineer to the Einasleigh copper mines, in Queensland.

JAMES MACNAUGHTON, general manager of the Calumet & Hecla mine, has received an honorary degree from the University of Michigan.

HUGH ROSE, assistant general superintendent of mines for the American Smelters Securities Corporation, is at Santa Barbara, in Chihuahua, Mexico.

HENRY S. WASHINGTON and J. VOLNEY LEWIS have formed a partnership as consulting geologists and mineralogists, with an office at 95 Liberty St., New York.

W. G. MOSHER was in San Francisco last week on his way to Kansas City. He has been associated with Chas. Butters & Co. at the Prietas and Divisadero mines.

Obituary.

CAPT. W. H. TAYLOR, president and one of the founders of the Risdon Iron Works, died of pneumonia on July 12 at his home in San Francisco. He is succeeded in the business by his two sons.

(By courtesy of E. F. Hutton & Co., 490 California St.)

from the 1,800-ft. level of the Maryland. The property adjoins the Norambagua, that is being worked by the Pittsburg Standard M. Co. The directors of the Belle Union are Ed. Dunkley, James Gluyas, C. M. Peek, W. P. Shaw, George Price, and Frank Russell.—The pumps have been started at the Banner mine. It will take six weeks to unwater the workings, which are full to the level of the drainage tunnel. When the mine is dry, the 900-ft. level will be run under the ore-shoot encountered in the old shaft.—Since bonding the Mountain View mine, on Canyon creek, E. B. Miller has installed a small mill and built 4,000 ft. of dume and laid 700 ft. of pipe. The mine is looking well.—Drifts are being run under the main channel at the Cold Spring mine, on Washington ridge, near the old Harmony. Good gravel was tapped recently, and as soon as enough ground was opened to allow of steady breasting the mill will be started. Thomas Coan is the foreman.—A new blacksmith-shop, dry-house, and office are being built at the Norambagua, and the main tunnel has been retimbered. The company is awaiting the arrival of steel rails for the tunnel.—The pay-shoot in the Champion and Home mines has been struck in a drift on the 800 level in the Home, which leads both these companies to believe that the shoot is going to hold with depth. In the Champion, a drift is

being run south on the 800 level, and this will connect with the bottom of the Home shaft. At the Champion mill 20 stamps are dropping, and 30 at the Home mill. James Moore is the foreman.—John J. Habecker and C. G. Michener of Philadelphia have made an inspection of the Giant Hinz mine, in which they are interested.—The new electric hoisting and pumping plant at the Ethel, 1,400 ft. from the tunnel portal, has been completed. A winze will be sunk on the vein at the face of the tunnel.

PLACER COUNTY.

The Santa Fe gravel mining company will soon start work on its property.—The shaft is down 40 ft. on the Dewey mine, which is being worked by Ned Gilbert.—At the Black Hawk mine on the North Fork, 14 men are employed and the tunnel is in 400 ft.—A clean-up of 73 oz. of amalgam was recently made by the lessees of the Stemples tailing mine.—All of the plant is in place at the Hathaway. Power will be brought from Newcastle. The power-line will be 3,000 ft. long. The motor is rated at 180 h.p., and the 20-stamp mill is modern in every detail. The lowest tunnel taps the vein at a depth of 600 ft. and the vein has been worked in places to the 720-ft. level. This mine lies between the Kirkwood on the east and the Eureka on the west. These mines will all be connected by drifts. They are owned by the Ophir Valley M. Co., composed of New York capitalists. A. B. Eastwood is the manager.

SHASTA COUNTY.

The Du Boise gold dredge that has been operating on the sands of the Sacramento river at Middle creek, is a suction dredge. Patents controlling this process have recently been allowed. The method heretofore has been carefully guarded. The sand and gravel in this vicinity are held in large crevices formed by the rock ridges crossing the bed of the river. These ridges form natural riffles from which the sand is lifted by the dredge to the treatment plates and riffles.

SIERRA COUNTY.

(Special Correspondence).—At the Sierra Buttes mine, near Sierra City, 60 stamps are running steadily and 112 men are employed. The mine is owned by the Hayes Brothers of San Jose and is superintended by J. E. Olsen.—At the Hayes Consolidated, which is owned principally by Jack and Phil Hayes, of Sierra City, the 20-stamp mill is nearing completion and will be in operation within three months. The mill will be run by water-power, the ore being transported from the mine to the mill 2,500 ft. distant, by means of an aerial tramway. Jack Hayes is the superintendent.—In Ladies canyon, the Sovereign Mines Co. is installing a sawmill to get out the necessary lumber with which to erect a 10-stamp mill, cyanide plant, office buildings, boarding house, etc. An air-compressor and machine-drills will be installed soon. About 35 men are employed and a road from Sierra City to the mine has been completed; the power ditch is ready to have the water turned in. Horace Morse is the superintendent.—The mill at the Keystone will be reconstructed before fall; it was taken away by a snowslide during the winter storms. Fred Perryman is the superintendent.—At the Alice mine in Jim Crow canyon, near Downieville, the five-stamp mill that was erected this spring is running steadily on ore that plates from \$5 to \$6 per ton. The company will install five additional stamps, concentrators, and a rock-breaker some time this summer. George McGee is managing the property.—It is expected that the Comet mine will have some development work done on it during the year.—Mr. Gilbert, of New York, has commenced cleaning out the tunnel at the Black Jack mine, situated in Jim Crow canyon. This property was operated successfully during the early eighties. A snow-slide took this mill away, and no work has been done since. The ore milled \$15 in free gold, besides carrying sulphides which were not saved at the time. At the Buckingham property, in Jim Crow canyon, the five-stamp mill is being run on high-grade ore. This vein is on the granite and slate contact that runs through this district from Nevada county.—At the West Point mine, situated at Monte Cristo, the tunnel is being driven ahead to intersect the White Bear channel, which was worked by

Wm. Belcher south to the intersection of the West Point ground. This channel was rich. The West Point company has three-quarters of a mile of this channel on its ground. John Peckwith has charge of the work at the mine.—The Excelsior company is driving the White Bear tunnel to intersect this channel. The rock is hard, making the progress slow. The Excelsior is owned principally by John Costa. John Schofield is superintending the work.—A. G. Hunter was awarded the contract to continue the main working tunnel 200 ft. at the Herkimer mine, at which point they expect to intersect the Bunker Hill channel.

Downieville, July 10.

The new wagon-road to the Sovereign mine is finished and the sawmill will soon be running, cutting lumber for the new mill.—The Sierra Buttes mine, at Sierra City, is operating full handed, and both the 60 and 20-stamp mills are running. About 125 men are employed and timber contracts have been awarded by the company, for 600,000 ft. of lagging and 100,000 ft. of poles.—Two shifts are working in the Empire mine, in Gold valley, 13 miles from Downieville. The 20-stamp mill is running. Operations were suspended six months ago, when the electric plant burned out.

SISKIYOU COUNTY.

John Garvey has sold his interest in the Garvey Bar river claim to the La Shells. This claim is on the Klamath river above the mouth of Humbug creek, and the bedrock gravel has been proved to be rich.—The directors of the Patterson Creek or Sheba quartz mine have levied an assessment of 10c. per share. Noel E. Groves is the superintendent.—The dredge at the Doggett mine on Klamath river has temporarily suspended operations on account of a break-down.—The Mono company is employing 30 men and is running two 2-stamp batteries.—The McKinley mine, with a five-stamp mill, will be operated again, by Eastern capital.—The Spencer mine has been bonded to Portland parties. The waste dump will be worked over again.—The Eliza company, composed of Portland people, and equipped with a 10-stamp mill, is considering the installation of a cyaniding and concentrating department.—The Heglen mine, which has a vein two feet wide, and is equipped with a five-stamp mill, is being examined by engineers.—The Boyl group, equipped with a Huntington mill and a four-stamp battery, has been bonded.—It is reported that the McKean mine, near Callahan, in southern Siskiyou county, is being operated with good results. It is owned by the Helena Gold Mining Co., for which A. Sydney Addison is manager. The new shaft will be sunk 250 ft. below the old workings.

TRINITY COUNTY.

The La Grange mine, the largest hydraulic mine in the world, has been recently acquired by the Bully Hill Copper Mining Co. of Shasta county. It is understood that the controlling interest in this mine is held by the General Electric people. The same group of capitalists are behind the Sacramento Valley & Eastern railroad, which is a broad-gauge road under construction to tap the mining and agricultural districts of the counties lying in the north-eastern part of California. This railroad forms a junction with the Southern Pacific railway at Pitt, in Shasta county, about 275 miles from San Francisco.

COLORADO.

TELLER COUNTY.

A big cave-in is reported at the No. 2 shaft of the Stratton Independence, on Battle Mtn. The roadbed of the Midland Terminal railway has sunk for a length of 400 ft. and the water-main supplying Victor has burst. The caved area covers about four acres.

IDAHO.

IDAHO COUNTY.

Two hundred thousand dollars is the price reported paid by F. W. Bradley for the Buster mine at Elk City, south of Spokane, owned by S. W. Smith. The Buster is a gold proposition and considerable development work has been done by Mr. Smith. The orebody has increased with depth until now it is 400 ft., with improvement east and west in

the lower drifts. Joseph Thorn is superintendent and the company will erect a 10-stamp mill and a cyanide plant, the former being equipped with 1,200-lb. stamps, and will be enlarged as the work progresses. Ground has been cleared for a power-house and head-frame.

Four feet of ore in a vein has been opened at a depth of 100 ft. in the Keno group, on Sheep Mtn., in the Rapid River district, in central Idaho. The property is owned by Charles Jansen and John Wilson. The strike was made at the face of the 175-ft. cross-cut tunnel. Assays gave returns of \$14.63 in silver and \$9.92 in gold.—A 14-ft. vein of gold-bearing ore has been cut on the 500-ft. level of the Gold Coin mine in the Seven Devils district. It is free milling. The Gold Coin, which is owned principally by residents of La Crosse, Wis., is equipped with a stamp-mill, which has been shut more than two years, while the long lower tunnel was being run.

ROOTENAI COUNTY.

While doing assessment work on the Graphite claims, east of Priest lake, Andres Coolin, principal owner, uncovered a vein carrying molybdenum. The metal is found in a dike of diorite which cuts through the granite, and can be traced for 700 ft. up the hill. The dike of diorite is fully 700 ft. wide, and the seams contain the ore.

Official announcement is made in Spokane that the Panhandle Development Co., the Panhandle Smelting Co., and the Ponderay Transportation Co. have been merged, the smelting concern, incorporated for \$5,000,000, being the parent organization. The development company, capital stock \$300,000, owned the townsite of Ponderay, including water fronts and water-power sites. The Ponderay townsite surrounds the smelter a mile and a half from Sandpoint. The transportation company, capital \$300,000, owned boats on Lake Pend d'Oreille, ore-barges and pile-drivers. None of the stock of these companies has been issued. They were organized as subsidiary companies. T. L. Lammers, manager for the smelter company, of which J. Herbert Anderson, of Chicago, is president, announces the capacity of the plant will be 100 tons per day when it begins operations. Two thousand tons are at the smelter and ore is being brought from Montana, the Coeur d'Alene, and the Pend d'Oreille Lake district, coke being shipped from Connellsville, Pennsylvania.

LEMHI COUNTY.

Lemhi county, east of Spokane, promises to become one of the rich silver-lead districts of the Northwest. The district has been shipping ore for years, but little is known of it. W. H. Jackson, engineer for the Federal Mining Co., recently visited the district, and pronounces it one of the best he has yet inspected. He believes that the Gilmore and Kaufman camps will prove to be rich. There are mines there that have produced as much as \$10,000,000. The Gilmore mine near the town of Gilmore last year produced more than \$200,000 above expenses of development work, and the product of the Gilmore has to be hauled about 80 miles overland to the nearest railroad. The ore is a lead carbonate, with no sulphides to speak of, and carrying an excess of iron. The smelters pay \$3 per ton more than for the average lead-silver ore. The district is an extensive one, but suffers from lack of transportation.

SHOSHONE COUNTY.

Ore cut at a depth of 350 ft. on the Lucky Friday vein recently proved richer in silver than any strike yet reported from the Coeur d'Alene. The tunnel was in 624 ft. when the lode was cut and gives 400 ft. of back. The main vein is 11 ft. wide. Next to the hanging wall, on a talc seam, is 18 in. of gray copper and galena in quartz, which assays \$2.60 gold and 110 oz. silver per ton, and 4.8% copper and 8% lead. Next to this lies a five-inch streak of ore which carries 100 oz. silver, 2.4% copper, and 36% lead. The pay-streak is four feet wide, the rest of it being rich enough to ship after hand sorting. Shipping will begin in 60 days. The Lucky Friday group consists of three claims and a fraction, and is a little way east of Mullan, near the Hunter mine. The principal owners are: George E. Potter, Walter A. Jones, J. E. Wade, M. B. Brownlee, Mrs. James Clark, Nuzum Brothers, Slater Brothers, Charles Lund, J. H.

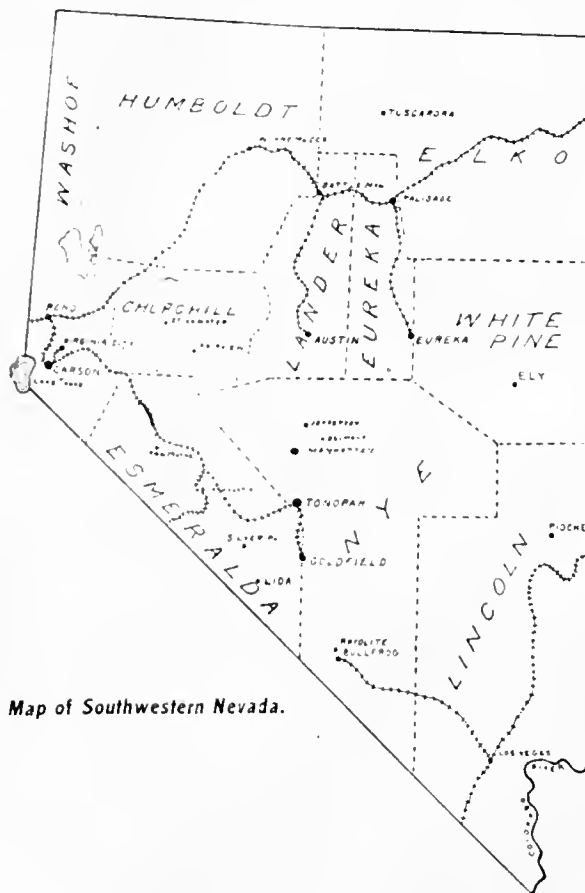

Wilnot, M. J. Gordon, W. T. Stout, and Edward Erwin.

—Active work on the development of the Reliance mine, an extension of the Black Cloud-California property near Wallace, has been started by the C. E. Mitchell company of Spokane. The property was not developed earlier owing to the fact that the owners lacked capital to push the work and were not willing to incorporate a company for development purposes. Control of the property was acquired by the Mitchell company, which is operating a number of mines in the Coeur d'Alene district. Cabins have been erected and a good wagon-road constructed to the property, the work being done under the direction of Sanford Daigle, superintendent. Work on the tunnel has been started and is being pushed day and night.

NEVADA.

CHURCHILL COUNTY.

(Special Correspondence).—The shaft at the Jackpot is 200 ft. deep, from which point a cross-cut will be driven. A 50-h.p. hoist has been installed at a shaft being sunk above the old one. A earload of ore is being sacked for

Map of Southwestern Nevada.

shipment.—A 4-ft. vein has been struck on the Hercules No. 3 claim of the Winder National Co. The high-grade ore is being sacked.—The Spider-Wasp Co. is working three shifts in the main shaft, which will be put down 300 ft. The Toohy, Watts, and Spider-Wasp Development leases are in ore.—The Nevada Wonder has commenced shipping ore. The shaft is down 125 ft., and will be sunk to the 400-ft. level.—Sinking on the Miami Wonder has been resumed, and a depth of 70 ft. has been reached. Some good quartz is in sight.

Wonder, July 10.

ELKO COUNTY.

(Special Correspondence).—A 10-ft. vein has been encountered in the placer workings operated by the Nevada Hydraulic M. & M. Co., one mile southeast of this camp. Two other veins carrying gold and silver have also been found.—A 14-in. vein carrying gold, with some silver, has been struck in the Coffee Pot shaft on the Independence group at Mountain City.—A strike of copper ore has been made 200 ft. from the face of the main tunnel on the Baltimore group on Lone Mtn. This property has been profitably operated for 12 years. The group is owned by the Pacific Con. Co.—Ore carrying copper, and some gold, has

been uncovered in the Little Marsh mine, near Carlin.—Ole Elliott, of Goldfield, has bonded several quartz and placer claims on Salmon creek, and has men at work developing them.—A 4-ft. vein of ore has been struck in the new shaft on the Jack Pot, at Aura, and a 2-ft. lode in the tunnel runs well.—The Mountain City group, with a record production of \$700,000, has been bonded by J. U. Myer. A 300-ft. shaft will be sunk.—The Protection and Silver Bill companies are working short-handed, because of the scarcity of miners.

Tuscarora, July 10

ESMERALDA COUNTY.

(Special Correspondence).—On the Mohawk claim of the Goldfield Consolidated a new vein was recently opened. This new strike was at a depth of 450 ft. in the company's shaft.—The Little Florence lease, on the property of the Florence Mining Co., is making steady shipments. Some of the ore is sacked and shipped, running \$150 per ton.—The Florence Ledge Co. has opened the Florence vein in its workings.—From the Mohawk-Jumbo lease on the Jumbo Extension ore is being shipped.—Among the newer leases the Combination No. 3 lease, on the Consolidated ground, is being developed by a double-compartment shaft that is down 200 ft. Some ore-shoots probably pass through this ground. The Atlanta is in ore, one of the lessees having opened a little bunch of sulphides in his shaft.—The Great Bend and Black Butte have encountered some ore within the past week.—Some leases will be given on the Lou Dillon and Silver Pick Extension claims. These two properties lie in the Mohawk belt, and some think that pay-ore will be found with proper development.

Goldfield, July 13.

(Special Correspondence).—The output of the Goldfield mines for the week ending July 6 was 3,417 tons, valued at \$590,000. Of this amount 1,972 tons were treated at the Nevada-Goldfield Reduction Works, 945 tons shipped to smelters, and the remainder handled at the Combination mills. The ore received at the Nevada-Goldfield plant was from the following properties: Mohawk Combination, 525 tons; Mohawk Jumbo, 275; Little Florence, 225; Sheets-Ish, 350; Red Top, 300; McNaughton, 80; Mohawk, 95; Reitz, 50; and Loftus & Davis, 42 tons of ore. The richest shipment came from the Mohawk, some ore running \$450 per ton.—The total production of Goldfield mines during the month of June was about \$1,142,000.—A 5-ft. vein has been encountered in the 420-ft. level of the Wedge claim on the Jumbo Extension.—Eleven cars of ore, containing 374 tons, recently shipped from the Little Florence, netted the company \$74,800.—It is reported that the Consolidated interests are endeavoring to secure control of the Jumbo Extension.—A good strike has been made in a cross-cut on the 200-ft. level in the Daisy. The vein is two feet wide. The find was made in the Krise lease, in the west end of Daisy No. 1.—Small stringers of ore have been discovered in the main shaft on the Diamondfield Black Butte. The ore was found at a depth of 300 ft.—Good ore is being extracted from the Combination. The highest grade is shipped to the smelters, and the rest is treated at the company's mill. One carload of ore to the Selby smelter, recently shipped, netted \$34,161.—The Walker Lake district, northwest of this city, is attracting attention. Ore has been found on Cottonwood creek, where a new townsite named Lake View has been laid out.

Goldfield, July 12.

LINCOLN COUNTY.

(Special Correspondence).—A find of good ore on the Duplex mine, which takes in the original discovery of ore in this camp is reported.—Good ore has been uncovered on the Spokane claim of the Searchlight Spokane Mining Co., within 10 ft. of the old wagon-road. A shaft has been started at this point.—Four miles southeast of the Spokane and one mile south of the Quartette Mining Co.'s Boston mine, on the property of the Searchlight Comstock Mining Co., another strike has been made. At a depth of 35 ft., a stringer was encountered and the shaft was sunk on an incline of 65°, following the vein. Sinking has been discontinued temporarily pending the installation of a gasoline

hoist that has been ordered.—The Silver Legion is taking out ore in the east drift of the 85-ft. level. The first shipment of 25 tons of ore from these workings will soon be made. Owing to the inflow of water no development will be done on the 185-ft. level until a pump is installed. H. E. Spanogle is the manager.—On the Majestic Goldfrog, some ore was encountered at a depth of 70 ft. and from that point the ore is improving. Bids for a shaft to water-level on the Stanley Forbes Extension are being received by L. J. Kaiser, the manager.

Searchlight, July 12.

NEW MEXICO.

SOCORRO COUNTY.

Good lead and zinc sulphides have been encountered in a tunnel on the Mistletoe group in the Magdalena district, 1,170 ft. from the portal.—George L. Brooks and L. N. Babcock recently transferred a bonded lease on the Lillie, Murice, and Little Flow claims in the Kelly district, to the Empire Zinc Co., represented by C. J. Brown.

WASHINGTON.

OKANOGAN COUNTY.

Ruby, a deserted mining town, near Conconully, west of Spokane, which was a thriving place 15 years ago, is likely to come again into the limelight. J. T. Plant, of Mora, Minn., inspected a property on the mountain side, and found signs of ore. The Washington T. & C. Co. will soon begin work on an 800-ft. tunnel under Mineral hill, near the town of Conconully. The tunnel will explore the ground of 56 mineral claims, and cut eight known veins. It will carry two tracks.—John M. Wentworth, of Loomis, has found what is regarded as a promising gold mine. It is located in the Horse Spring coulee, seven miles east of Loomis. He has an option on the property, and is making arrangements to develop it at once. The gold lies in a limestone formation. A company has been formed by M. D. Thomas, Harvey Thomas, and Newton Thomas, Judge Steiner, of Waterville, and W. D. Wright, of Coeur d'Alene, and is incorporated for \$1,000,000 to develop the Steiner group of six properties, five miles from Okanogan.—The Mountain Sheep mine, near Loomis, will soon join the shipping class. Silver ore recently found is being sacked preparatory to forwarding it to one of the smelters.

STEVENS COUNTY.

Reports from Chewelah, northwest of Spokane, show that a strike of importance has been made on the United Copper Co.'s property, near that place, at a depth of 350 ft., the tunnel being in good copper ore at 600 ft. The vein, which is of white quartz, is from six to eight feet wide. Conrad Wolfe, of Spokane, president of the company, announces that it is planned to carry the cross-cut ahead until the hanging wall is reached, and it is expected to ship within two weeks. The property is equipped with a 1,200-ft. tramway.—At the 180-ft. level of the Jay Gould mine, near Chewelah, 15 ft. of galena ore has been cut, according to F. C. Bailey, superintendent of the property. The lode lies between granite and porphyry walls. Six feet of the vein is rich ore, part of which will bear shipment. The whole Chewelah district is looking up, and important developments are under way. At the Nellie S. mine a six-foot vein of copper ore was recently cut at the 200-ft. level. At the United Copper property a body of copper ore has been opened at a depth of 350 ft. Many other properties are being worked, and the camp is getting away from the hoodoo which has held it for years, for development at depth is proving the value of the orebodies of the district.—Forty thousand dollars, 10% down, is the price of the bond taken by the Dominion Exploration Co. on the Davis & Park group of seven claims in the Metaline district, north of Spokane, the buyer being Frank Brown, who has put a crew at work. He has associated with him several capitalists in New York and Toronto.—Stockholders of the Silver Peak Mining Co., at their annual election named the following directors: Conrad Wolfe, Spokane, president; F. R. Clark, Spokane, vice-president; Capt. Hugh James, Houghton, Mich., second vice-president and general manager, and Gale Smith, Spokane, secretary. The company owns 200 acres of ground in the Chewelah district. A 90-ft.

A circular recently issued to the shareholders of the Ymir Gold Mines Co., announces that a raise from the 1,000 to the 700-ft. level is completed and that good ore has been developed by it. The 20 stamps will soon be dropping. H. C. Nichols is the manager.—Reports from the superintendent of the Moresby Island Syndicate mines, state that the Collision Bay group is showing up well. R. J. Leckie is the president.—The Diamond Vale Coal Co., operating in the Nicola valley, will soon be shipping 500 tons per day. Two exploratory tunnels have been run, and the railway switches are finished.—The Bear hydraulic mine on Cunningham creek, near Barkerville, is being examined by engineers.—A contract has been let to drive a 300-ft. tunnel at the Enderby coal mines, where good coal has been discovered.—The Eva mine, at Camborne, will have a second stamp-mill, with 100 stamps. This property has been paying dividends for two years, and when 120 stamps are dropping, the production will be increased.—The Silver Dollar mine, that has been developed for five years by Indiana capital, has a new 40-stamp mill.—The Broadview mine, eight miles east of Beaton, has been operated since last September by Cincinnati people, who purchased it for \$35,000. A 500-ton concentrator has been planned for the property.

Special Correspondence.

Butte, Montana.

Smoke Litigation.—Discovery in the Greenleaf Mine.—Good Development in the Corra.—Butte-Montana Co.—Prospecting on the Continental Divide.

According to rumors a decision in the injunction and damage suit brought against the Anaconda and Washoe companies on account of smelter smoke, by a syndicate of farmers in the Deer Lodge valley, may be expected within a month or six weeks. The farmers look for an injunction to stop operations at the big Anaconda smelter, and it is conceded that they will be awarded substantial damages by the Master in Chancery, who has the case under consideration. The farmers and their attorneys base their expectations on the Federal Court decision in a case against the smelter at Ducktown, Tenn., a case claimed to be identical with that of the Anaconda and Washoe, except that the latter is much stronger for the farmers than that of the Ducktown case. In the latter the company was given time in which to settle with the complainants, and the injunction does not go into effect until the first of October, and then only if the complainants ask for it. Before the suit was brought against the Anaconda and Washoe, the latter could have settled with the farmers by buying their land at \$18 per acre, and the entire valley could have been purchased for about one million dollars. It is understood that the legal department of the companies favored a settlement on some compromise basis, but that the operating department opposed it, and insisted on a fight to a finish.

The vein cut in the shaft of the Greenleaf by the Boston & Montana Co. is estimated to be 11 ft. wide at the point where it was cut at a depth of 840 ft. It does not contain much commercial ore there, but has several stringers of copper sulphide. The vein is typical of Butte, it strikes almost east and west, with a strong southern dip. It is probable that a cross-cut will be run to the vein at a depth of 1,000 ft.—The shaft of the Badger State has reached a depth of 450 ft., and will be sunk at least 1,800 or 2,000 ft., and no cross-cutting will be done above the 1,000-ft. point. The Badger State is also owned by the Boston & Montana Co., and the work on it is in charge of Edward Renouard. The Badger State has one of the rich veins of the North Butte Co., and it is for the purpose of developing it that the deep shaft is being sunk.—The Alliance Co. has made several shipments of ore during the past week, and could have shipped more but, like other small companies, it has been unable to get cars from the railroad. The Alliance is stopping on the 200-ft. level, and has a lot of ground opened on the 300. The Farrell Co., which is operating through the Alliance shaft, is making good headway in developing its vein on the 200-ft. level.

The Butte Coalition Co. has made an important strike in the Corra mine, at a depth of 2,100 ft. The Corra has been a low-grade mine, and was one of the properties taken over from the United Copper Co. at the time of the settlement of the Heinze-Amalgamated litigation. During the Heinze operation of the Corra the only vein of importance was on the 1,600-ft. level, and that appeared to pinch out. The new owners were doing some exploration work when a vein of sulphide ore, running at right angles to the orebody on which Heinze had been working, was opened, proving to be a large lode of low-grade ore. The Coalition Co. then opened the vein on the 1,500 and 1,400-ft. levels and has been mining it, and at the same time has been sinking the shaft. Some time ago

the apex of another vein was cut at a depth of 1,900 ft., and last week a cross-cut was run on the 2,100-ft. level, and a big body of first-class ore opened. The vein at the 2,100 is 46 ft. wide and the report from the mine is that nearly the entire width is first-class. Some driving has been done on the vein and as yet the ore continues of the same extent and quality as in the cross-cut. The belief of the management is that the Corra is destined to become one of the best mines of the Coalition Co. The mine is in the Walkerville part of the district and a short distance southeast of the Alice mine. It is the farthest north of any producing copper mine of consequence. The shaft is now down 2,200 ft. and is to be connected at that depth with the Diamond mine for purposes of ventilation, drainage, and safety.

The Butte-Montana Mining Co. is engaged in an effort to raise money sufficient to take up the bond on the Alex Scott mine, which will fall due in August. The company is offering treasury stock in Butte at 50c. per share, accompanied by a receipt from the First National bank, in which the latter guarantees the return of all subscriptions in the event the bond on the property is not taken up. About 50,000 shares are offered in Butte, and the remainder of the money is to be raised at Pittsburg. The bond is for \$150,000, and \$20,000 has been paid on it. The company claims it has \$1,000,000 worth of ore in the Alex Scott, and the reason offered for not taking out some of it and paying for the property is that the company, under the conditions of the bond, would have to pay 25% royalty to the owners of the property, but which it is saving to the stockholders by not mining the ore. The company is sinking the shaft of the Alex Scott, which is down between 900 and 1,000 ft. The shaft is to be made 1,500 ft. deep.

The Corry people, who are operating mines in the Continental district on the mountain range east of Butte, are preparing to sink a new shaft. The work on the Rex claim has been temporarily suspended, as the object of the work has been attained. The Rex shaft is only 160 ft. deep, but the showing in it is good, a fine vein having been opened. The intention of the Corrys is to sink several other shafts on different portions of their property and develop them sufficiently to demonstrate their value. They are building a sawmill near the site of the proposed shaft and will provide their own timber, the claims being well covered with it. An air-compressor is also being put in place. It is the intention to run a large and long adit from the west side of the range to open the property at a depth of 2,000 ft. as soon as the surface work is completed.

Mexico City.

Consolidation of Railroad Companies Under Government Control.—Details of the Scheme.—Hope of Better Service.—American Society of Civil Engineers.—Convention in Mexico.

When writing my letter of last week the wish was father to the thought, and I was not aware of the fact that the actual merger of the National and Central railroads of Mexico was so near consummation as it is shown to be in issue of the *Official Daily* (the Government organ), of Saturday, July 6. This contains a draft of the law that Congress will be asked to authorize for the merger of the present lines controlled by the Government with the Central under the name of the National Railways of Mexico, organized as a limited liability stock company under the laws of Mexico with the home offices in the City of Mexico. The incorporators are to be the Mexican Government together with a group of stockholders of the present National Railway Co. of Mexico, and the Mexican Central Railway Co.,

and in order that a Mexican official may act for the Government it is to be expressly stipulated that one need not be a stockholder to be a director of the company; and nothing shall be allowed to prevent the Government from having control of the stock, or a majority holding, in the case of either an increase or decrease of the capital stock except by special act of Congress. The first organization will be with a capitalization of P460,000,000, of which P60,000,000 are to be first preferred shares, P250,000,000 second preferred, and P150,000,000 ordinary shares. The first preferred shall come first to the extent of 4% per annum dividend, before any payment is made on other shares, but said dividend shall be paid only

redeemable between the year 1917 and 1957 by means of a special sinking fund, though the company reserves the right to redeem before 1957 and may arrange to refund at 5% above the nominal value; the general mortgage bonds may not exceed P372,000,000, bearing 4% interest and redeemable between 1937 and 1977, but no arrangement can be made to refund above par as may be done in the case of the preferred. Both classes of bonds are guaranteed by a mortgage upon all the present and prospective holdings of the company, and the general mortgage bonds are further guaranteed by the Mexican Government. It is certainly to be hoped that the same may be consummated with the least possible delay,

Map of Mexico.

when earned and shall not be cumulative. The second preferred shall, after the payment of 1% on the first, be entitled to a 5% per annum dividend, before any payment on the ordinary, but likewise conditional, as in the case of the dividend on the first preferred, upon the earnings and non-cumulative. Any balance available from the net earnings in any year, after the payment of 1% on the first preferred and 5% on the second preferred, will be distributed among holders of the second preferred and the ordinary shares without distinction between the class of said shares. The initial shares, besides a block to be allotted to the Government, will be used for the acquisition of the properties and securities of the present National Railway Co. of Mexico and the Mexican Central Railway. The company may also issue preferred mortgage bonds and general mortgage bonds, the former to be limited to P162,000,000 bearing 1 1/2% interest and

and judging from the recent earnings of the companies to be consolidated, it should be an excellent investment for the general public; and the merger should enable a great general saving by a material reduction of office and operating force and expenses and an increased earning by more profitable routing of all goods handled. A very material improvement in the general railroad services throughout the Republic should be one of the immediate results. Many of the much-needed branches will be built, and the several transcontinental lines will be pushed rapidly to completion. And the company may acquire other roads already built or to be built as the needs or advisability of obtaining such are made evident. The annual convention of the American Society of Civil Engineers held its first session in Mexico City on Monday evening, July 8, the day having been given to trips around the City as guests of the tramway company.

Tuesday was given to a visit to the President's home and the military school at Chapultepec and the City water works as guests of the Water Works Commission, with a business session at night. Wednesday is to be given over to sessions morning, afternoon, and evening. Thursday and Friday will be spent in a trip to the power plant of Necaxa, as guests of the Mexican Electric Light & Power Co., while Saturday is to be taken up with regular sessions. Monday, July 15, the Society will be the guests of the Mexican Government on a visit to the City drainage works. Tuesday a trip is to be made to Cordoba and Orizaba, while on Wednesday, July 17, those who desire will be taken over the line of the Tehuantepec National railroad as the guests of S. Pearson & Son. The subjects to be discussed during the convention are to be under the general heads of 'Water Supply,' 'Foundations,' 'Pavements,' 'Electric Railways,' and 'Gas Engines.' It is expected to be a most satisfactory gathering, and several hundred engineers are in attendance. L. M. Terry and associates, of New York, who recently purchased the Concepcion and Cocineras mines, in the Santa Eulalia district, of Chihuahua, for \$60,000, have started development work. Mr. Terry and his friends now control about 270 acres of mineral land in the proved part of the Santa Eulalia district,—A. W. Geist of Guadalajara has secured an option to purchase the Estrella mine, in the State of Jalisco, from Felix Araiza of Guadalajara for \$100,000. — Regular shipments of ore are now being made from the Magistral copper mine in the Etzatlan district, of Jalisco, to the San Luis Potosi smelter. The ore runs about 9% copper and carries gold and silver. The mine is owned by the Magistral Mining Syndicate, which has its headquarters at Los Angeles. M. N. Graves is general manager.

Salt Lake, Utah.

The Garfield Concentrator.—Ontario Drainage.—Heinze's Operations. — Shipments From Tintic.—Dividends. — The Western Pacific Railroad.

The fourth section of the new Garfield mill of the Utah Copper Co. has been placed in commission and is now reducing to concentrate 2,000 tons of ore daily. The Copperton plant, owned by the same company, and situated in the lower Bingham canyon, is treating 1,000 tons daily. The management states that the company is now producing on the basis of from 30,000,000 to 35,000,000 lb. copper annually. The fifth and sixth sections of the Garfield mill will be in operation about August 1.—A receiver has been appointed for the property of the Silver King Consolidated mine at Park City, and W. H. Shearman of the Commercial National bank of Salt Lake City has been named. The company has an indebtedness of about \$75,000. The mine is equipped with one of the finest hoisting plants in Park City and a great amount of money has been expended in development without finding ore of commercial value. —The pumping operations being carried on by the Ontario Silver Mining Co. at Park City are progressing satisfactorily and the management has expressed the confidence that the water will be lowered to the adit-level within a short time and the task of removing the obstructions in the adit resumed.

It is believed here that the plans of F. Augustus Heinze in this State in regard to the building of a new smelter are about to mature. While no definite information has been released from an official source as yet there is little reason to doubt that the agents of Mr. Heinze have secured the ground required for a site and that it is outside the agricultural districts of the Salt

Lake valley. The Miners' Smelting Co. has been organized in the State of Maine with a capital stock of \$10,000,000. This is believed to be a Heinze enterprise and it is said the proposed smelter will have a capacity for the treatment of 3,000 tons of ore daily. The mines in Utah in which Mr. Heinze figures conspicuously are the Bingham Consolidated properties, Silver King Coalition, Western Utah Copper, and Ohio Copper. An option has also been secured on the Bluestone copper mine at Yerington in Nevada.

The ore and bullion shipments from the Tintic district last week aggregated a total of 111 carloads, the contributing mines and amounts being: Ajax, 1; Beck Tunnel, 9; Bullion Beck, 5; Centennial Eureka, 34; Colorado, 6; Carisa, 8; Eagle & Blue Bell, 4; Grand Central, 3; Lower Mammoth, 5; La Clede, 1; May Day, 1; Mammoth, 5; Ridge & Valley, 3; Star Con., 1; Swansea, 1; Sunbeam, 1; Scranton, 7; Tintic Iron, 6; Uncle Sam, 5; Yankee Consolidated, 4 carloads. Four Tintic companies have posted dividends this month, the Colorado Mining Co. taking the lead with \$120,000; Beck Tunnel, \$40,000; Grand Central, \$10,000; Lower Mammoth, \$9,500. The Colorado began paying dividends three months ago, two of \$40,000 each, making the total to date, \$200,000. Recent developments in this mine have been of such a satisfactory character that it has come to be regarded as being one of the big mines of the State. Some are of the opinion that it will even surpass the Centennial Eureka.

The Western Pacific railroad, now building toward San Francisco, is completed westward from Salt Lake about 140 miles and official announcement has been made that the operation of regular trains will begin some time in August between Salt Lake City and Steptoe, Nevada, the latter being the junction point with the Nevada Northern railroad, which has Ely for a southern terminus. The Western Pacific route will materially reduce the distance by rail between Salt Lake and Ely and will in all probability get the bulk of the passenger business between the two points.

A. J. Bettles, the mill manager for the Boston Consolidated, has come out with a statement to the effect that he expects to have the first unit of the new concentrating mill of this company ready for operation not later than August 1, and that it is the intention to begin work on the second unit by the time the first one is out of the way. The completion of the second will eventually bring the capacity of the plant up to 6,000 tons of ore per day.

A Michigan operator, J. R. Van Evera, has secured a controlling interest in the Little Chief mine at Tintic. Jesse Knight and associates of Provo have also purchased a controlling interest in the Sioux Con. mine in the same district.

The strike of employees in the Silver King mill has been settled. The men agree to return to work on the old schedule on the assurance that the wage matter will be taken up later—when the pending consolidation is finally completed.—The Nevada Utah Mines & Smelters corporation has purchased the Imperial mine in Beaver county; also, the Manhattan group at Pioche, Nevada. It is said the company has \$1,000,000 in the treasury after having paid for the above-named properties.

The management of the Little Eddie Mining Co., operating at Bingham, has reported important developments. In the adit, through which the main development of the property is conducted, a large body of ore has been encountered. Edward McCarrick of Salt Lake is manager.—The Ophir Hill Mining Co., at Ophir, has secured an option on the Hidden Treasure mine in Dry canyon and a compressor plant is being installed.

Toronto, Canada.

Labor Troubles.—Activity at Larder Lake.—Exploration in Labrador.
Shipments from Cobalt.

A general strike of union miners at Cobalt was declared this morning and about 2,000 men are idle. At a union meeting held on Saturday, July 6, it was resolved to oppose the schedule of wages adopted by about 30 of the mining companies, and to strike wherever this schedule had been signed by the mine owners. A union schedule was drawn up fixing the pay of surface men about 50c. per day higher than the rate of the mine owners' schedule, and demanding a 10-hour day for surface workers (8 hours on Saturday) and an 8-hour day for all underground work. A deputation was appointed to wait on the mine owners who had not signed the schedule and request that they meet the union's demands. About 600 miners have joined the union during the past week.

The strike at Cobalt, which during the fore part of the week practically closed up nearly all the mines of the Cobalt district, had not at last accounts affected Larder lake, where a good deal of activity was reported. An important find was made on the Lucky Boy's property, consisting of a 20-ft. vein of copper running along the northeast arm of Larder lake near the Dr. Reddick claim. The vein also carries gold. Development work has commenced on the 14-ft. vein recently found on the Larder Central Goldfields location and the free gold in the ore is found to increase with depth. Good discoveries are reported at Moosehead lake, some eight miles north of Larder City, samples brought by prospectors showing native gold and native copper. The region has never been prospected till this year, and is now attracting much attention. The belief is general that the country lying between Larder lake and Abitibi, 35 miles to the north, is all a gold producing area.

A party of prospectors headed by C. H. M. Johns, of Toronto, leaves shortly to look for gold in the wilds of Labrador. They are understood to be working in the interests of American capitalists who are in possession of information indicating the particular region where gold is likely to be found, but their precise destination is kept a close secret. Dr. Dowling, a well known geologist, who has charge of a party sent out by the German Development Co., of Montreal and Ottawa, to explore the Rocky Mtn. region, reports the discovery of coal deposits near the Yellow Head Pass, where the Grand Trunk Pacific and Canadian Northern railways will cross the mountains.

Ore shipments from Cobalt for the week ending July 6 amounted to 319 tons, the following being the shipping mines: Buffalo, 60 tons; Coniagas, 136; La Rose, 30; McKinley-Darragh, 24; Nipissing, 51; Imperial Cobalt, 18 tons of ore.

The old Wright silver and lead mine on the Quebec side of Lake Temiskaming, which has been closed down for a year owing to heavy smelter and transportation charges, is to be re-opened. The Del Norte Smelting & Reduction Co., an Arizona corporation, with \$10,000,000, has secured control, and will erect a smelter to treat the output at Ville Marie, Quebec, some 13 miles across the lake from Haileybury, Ontario. The contract has been let, and the work is to be completed in one year. Six other shafts are being put down near the Wright, activity being stimulated by the prospect of a smelter in the neighborhood. The town of Ville Marie is assisting the enterprise by giving a free site, a cash bonus of \$8,000, and exemption from local taxes for twenty years. It is also anticipated that a supply of ore for treatment will be furnished by Larder Lake, and the regions farther to the

north. The company has not yet decided as to whether they will be able to handle Cobalt ores.

Pioche, Nevada.

Railroad Construction.—Nevada-Utah Co.—Ohio-Kentucky.—The Phoenix Reduction Co.—Increased Activity.

The branch of the San Pedro, Los Angeles & Salt Lake railway (generally called the Clark road), now under construction from Caliente to this place, is progressing fairly well, although it has not come forward quite as rapidly as we expected. The Clark road is re-building, reinforcing, or otherwise protecting over 50 miles of its line from Caliente southwest, which was washed out by the floods of last winter, and must use a force of laborers that it might otherwise spare for the Pioche branch. Of

The New Mining Regions of Ontario.

this branch the grade is completed for more than two-thirds of the distance, and track has been laid eight miles out of Caliente. There was delay in tracklaying for some weeks, waiting for the mechanical tracklayer to come from the Las Vegas & Tonopah Railroad, but it seems that it will be needed on that line so long that it was decided to go ahead and lay the rails by hand. The railroad company expects to open the line to Bullionville, 12 miles below here by wagon-road, this month, clear through to this place in September.

The Nevada-Utah Co. is doing a little house-cleaning, while waiting for the railroad to bring in the vast amount of construction material required by them. They have erected out of lumber hauled on wagons a boarding-house and a bunk-house and are ready to ship ore from several

places on their property. Their principal shipper at first will be the Jack Rabbit mine, 15 miles west from here, where it is said that they have half a million tons of ore opened up above the adit level. It is a silver-lead ore, carrying a high percentage of lime (being a replacement in limestone), and of course it is in eager demand at the smelters.

The plans of this company contemplate greatly increased hoisting facilities and a pumping plant adequate to sink to a depth of at least two thousand feet. A light and power plant of at least 1,000 h.p. is to go in on the hill just as soon as it can be installed after the railroad is available. This will furnish the town of Pioche with electric light and also serve the needs of the company for light, hoisting, pumping, and air-compression. They will build a large concentrator, as well as a sampler, near the depot. At Jack Rabbit they will erect a 500-h.p. power-plant for their own use, and perhaps larger, in order that they may sell power to the neighboring camps. They will start a vigorous system of development on the old mines under their control. Most of those on the hill are already connected underground. This system will be perfected and all the ores brought out either through the main hoist on the hill, or through the old Pacific adit.

Since my last letter this company has elected a new president, George W. Learned, of New York. C. H. Swanton of Pioche is general superintendent of all the properties in Nevada. There has been a great deal of speculation as to whether the company is now actually dominated by Thomas W. Lawson, of Boston, but no one in this region seems able to answer the question. Since they anticipated the provisions of their option, and filed deeds conveying to them complete title to all their properties in this region, the news has been published that they have also purchased the Manhattan group of claims near the summit of Stampede Gap, ten miles west from here.

The Ohio-Kentucky, of which Samuel Newhouse is president, is crowding development. This company owns a large amount of the most valuable property on the hill, and is today developing with most vigor the Susan Duster lode, by an incline shaft. The mine is a new one. It is equipped at present, for development only, with a 25-h.p. gasoline hoist. The shaft was started on a 60° incline for reasons best known to the management. This will probably be used for ventilating and for dropping ore to a lower level. The shaft, which has reached a point over 50 ft. below the third level, is still going down. From a drift on the second level a winze has been sunk 35 ft. and a raise is coming up from the third level to meet it. A winze is going down from the third level and driving both ways on the vein is proceeding also on that level; later cross-cuts will be run from both of these drifts. These workings are simply to test the orebody. In places, where the full width of the vein has been disclosed, it has been found to be over 20 ft. wide. The ore is a complex sulphide of lead, zinc, and iron, carrying gold and silver. Only so much as comes out in development is being hoisted and that at present is going onto the dump for eventual shipment.

The same interests that control the Ohio-Kentucky, but in different proportion, control the Phoenix Reduction Co., which is going to be one of the institutions of this region.

Besides the old tailing-piles at Bullionville and Dry Valley, where the ores of the Raymond Ely and Meadow Valley companies were treated in the early days, this company owns a group of claims $2\frac{1}{2}$ miles southwest of Pioche, known as the Prince group. This is a low-grade silver-lead ore, carrying an excess of 30% iron. It is also a replacement in limestone and from its nature evidently such an ore as the smelters greatly desire.

E. L. Godbe, the general manager, tells me that the ore outcrops practically 1,000 ft. in length by from 100 to 200 ft. in width. They have recently installed a 40-h.p. gasoline hoist over a shaft already down 120 ft. At the 100-ft. level they have run in a cross-cut over 40 feet.

Cripple Creek, Colorado.

Mill for the Independence.—Pumping in the Gold Coin.—Operations of Leasing Companies.—Dividends Paid.—Ore Treatment.

The shareholders of Stratton's Independence, Ltd., at a special meeting recently held in London, have authorized the erection of a mill for the treatment of the dump and low-grade ores of the mine. Operations will commence July 8, clearing the site, which is to be where the houses of Strattonia now stand. The mill will be a combination of concentrating and cyaniding and is to be built in units, each of which will have a capacity of 6,500 tons per month, to be made up of approximately 5,000 tons from the dump and 1,500 tons from the mine. It is estimated that there are approximately 600,000 tons of rock on the dump that will average about \$3.50 per ton.

The water in the Gold Coin shaft of the Granite Gold Mining Co., situated in the city of Victor, has been lowered to the 1,200-ft. level. This has been accomplished by means of the pump on the 1,000-ft. level, the sinker on the 1,100-ft. level, and two bailers in the shaft. It is stated that the expense of keeping the water down to this level will be borne by the Granite, Strong, Ajax, and Portland companies.

Cavanaugh & Co. who have been operating on the lower levels of the Wild Horse mine on Bull hill, have turned over their lease to the owners of the property, the United Gold Mines Co. The lessees have been mining the low-grade oxidized ore from these levels, treating it in the Wild Horse mill. A final clean-up is now being made by them at the mill. Operations were conducted through the old shaft, which the company has taken over, but the latter will allow the subleases, granted by Cavanaugh & Co., to continue in force. The above parties also have a lease between the 200 and 400-ft. levels of the main shaft where they are mining a 4-ft. vein averaging \$40 per ton.—The El Paso Gold Mining Co. paid a dividend to the stockholders of \$24,500 on the 25th ult., and the Elkton Consolidated G. M. Co. a dividend of \$37,500 about the same date.

The total of dividends paid by companies operating in this district reaches \$1,200,000 for the first six months of 1907. These are the figures that are made public; several companies do not give out any information, and these, together with the profits accruing to lessees, would greatly swell the total. The Golden Cycle Mining Co. is shipping 12 cars daily to its mill at Colorado Springs. The mill is also treating custom ores; a total tonnage of about 700 tons per day is now being handled. The use of amalgamating pans and plates in the mill has been discontinued, as it was found impossible to prevent the plates from scouring, and to keep the mercury and amalgam from getting into the percolation tanks. Blankets have been substituted for the plates and they are giving satisfaction. The use of plates to catch the shot gold obtained by roasting coarsely crushed ore has the further disadvantage that the coarse pieces of sylvanite require a long exposure to the heat to free them completely of their tellurium, and until they are free of tellurium they will not amalgamate. The trend of sentiment in the district seems to be strongly toward all-sliming methods, and the Vindicator and Portland companies are engaged in experimenting with new types of filter-presses, to ascertain whether they are of practical value.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

IN using the hydraulic elevator in alluvial mining, the height to which the gravel can be lifted is one fourth the effective head.

AN occurrence of alluvial copper mining is known in the Sacramento mountains, in Otero county, New Mexico. There the overburden above a lava formation containing chalcocite has been sluiced successfully.

THE rare metal tantalum is now quite extensively used as a filament in incandescent lamps. While tantalum lamps are more expensive than the bulbs fitted with ordinary carbon filaments, they are longer-lived and give a much brighter and whiter light. It is figured that one pound of tantalum metal is sufficient for 23,000 lamps of 25 candle-power each.

WASHED METAL is cast iron from which most of the silicon and phosphorus have been removed by the Bell-Krupp process without removing much of the carbon, so that it still contains enough carbon to be classed as cast iron. The name 'washed metal' is extended to cover this product even if its carbon is somewhat below the proper limit for cast iron.

INGOT IRON is steel cast into an initially malleable mass and containing so little carbon or its equivalent that it does not harden greatly on sudden cooling. The word is rarely used in English, 'low-carbon steel' or 'soft steel' being generally used in its place. In America the line between soft steel and half-hard steel is usually drawn at a carbon content of about 0.20 per cent.

MAGNETIC SEPARATION has heretofore been confined principally to the separation of iron ores from gangue, or from other heavy minerals. Magnetite is separated directly, but limonite, hematite, and siderite are given a preliminary roast to convert them into the magnetic oxide. The separation of blende from pyrite, or other iron ores, is readily effected magnetically after such a preliminary roast.

MALLEABLE PIG IRON is an American trade name for the pig iron suitable for converting into malleable castings through the process of melting, treating when molten, casting in a brittle state, and then making malleable without remelting. The term should be used with care to avoid confusion. This material is also called in trade in America malleable iron, but this use should be avoided, because malleable iron has the older and (in Great Britain) firmly established meaning of wrought iron.

THE world's output of aluminum is about 15,000 tons, of which the American concern situated at Shawanegan Falls, Canada, supplies about 20%. The metal is being availed of in so many ways in recent years as to make it a precious one. The only method by which aluminum has been produced in any considerable quantity is by the Hall process of manufacture from the oxide, but an American inventor has produced a process for refining the metal by electrolysis which may bring about its wider use under more advantageous conditions.

A PRACTICAL method for discovering the presence of sulphur in petroleum is the following: Heat one or two grams of oil in a hard glass test-tube with a small piece

of sodium, allowing the condensed vapor in the upper part of the tube to run back on the sodium. Finally heat until completely dry, add a little water, and place a drop of the solution on a silver coin. A gray or black spot showing on the coin indicates the presence of sulphur in the original sample. Another method, that may be used if the oil is colorless, is to boil it for a few minutes with alcohol and a few drops of ammonia. Then add silver nitrate solution, and a brown coloration proves the presence of sulphur in the oil.

THE condition of the monazite market in the United States in 1906 was fairly strong, despite the fact that the price of thorium nitrate, which is manufactured principally from monazite, was reduced nearly one-half early in the year by the German thorium combine. Though made with the intention of killing all competition, this cut has resulted only in the temporary closing down or the bankruptcy of a few of the smaller companies. The economic value of monazite lies in the incandescent properties of the oxides of the rare earths—cerium, lanthanum, didymium, and thorium—which it contains. The cerium goes to the drug trade; the thorium, together with limited quantities of lanthanum and didymium, is used in the manufacture of mantles for Welsbach and other incandescent lights.

A PECULIARITY of the antimony industry is that while antimony ore exists in varying quantity in many parts of the world, three or four countries in turn within the last 30 or 40 years have supplied the bulk of the production. Makers of antimony metal and its chemical compounds at one time were dependent upon Portugal for supplies of ore; the Straits Settlements at another period satisfied the demand, and within the last few years it has been China. The current belief is that prices for antimony metal will continue high until deposits have been discovered which can be worked on as large a scale as those furnishing the shipments that have been made from China. Prospects that Japan, for many years an important factor in the market, will continue to ship appreciable quantities of antimony are not encouraging, as the domestic ore deposits are understood to be exhausted, and supplies from China will not be as plentiful as they have been during the last six years or more.

AVERAGE PRICES of mica vary widely for the different sizes. In North Carolina, the values reported by dealers range from 10c. and 25c. per lb. for stove mica down to five cents and less for electrical mica. Cirkel, in his report on the mica of Canada, quoted prices for medium-quality Canadian muscovite as ranging from 12c. per lb. for 1 by 3-in. thumb-trimmed, to \$1 for sheets 4 by 6 in.; for phlogopite the prices quoted for the same sizes are 10c. and 75c., respectively. The combined specific duty of six cents and ad valorem duty of 20% on rough-trimmed mica would aggregate from 80 to 25% of these prices, respectively. Scrap mica is valued at from \$5 to \$10 per ton in both the United States and Canada. The duty prevents importation of either the Canadian scrap or ground mica. The latter is quoted at from 5 to 10c. per lb., but the ground phlogopite lacks the luster of the muscovite. The present condition of the industry in this country is that the demand is good for the larger sizes of sheet mica for glazing purposes, for which use the muscovite is superior to the darker-colored micas of India and Canada; the smaller sizes of sheet can be cut into electrical mica, and the waste mica is available for the manufacture of micaite and other varieties of built-up mica board and also for grinding into the various grades of ground mica and mica flour. Thus the run of the mine can be utilized, to a great extent.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Conveying Tailing Through Pipe.

The Editor:

Sir—In reply to your request for further data concerning the pipe-line for conveying tailing, mentioned in your article appearing in the issue of June 29, I beg to say that this line is 5,440 ft. long, of 8-in. cast-iron bell and spigot pipe, $\frac{5}{8}$ -in. thick and joints calked with hemp rope loosely driven into place after having been tarred. It is laid for its first 800 ft. on a grade of $3\frac{1}{2}\%$, after which it has a uniform grade throughout of $2\frac{1}{4}\%$. The pipe-line was most carefully asphalted on the specifications for asphalted pipe contained in the proceedings of the American Institute of Mining Engineers two years ago, and was made by the American Cast Iron Pipe & Foundry Co. at Anniston, Alabama, no special price being paid for said asphalted, which is part of their regular practice, apparently.

The line of pipe passes through a crowded city and has in its construction many curves, the majority of which are on a 14-ft. radius, the curves being made by short sections of curved pipe in 3-ft. and 6-ft. lengths, ordered for that purpose. At the head of this line are two de-watering cones of 20 ft. diam. with 45° sides; these remove about one-half of the water from an 8 to 1 pulp before introduction into the pipe.

The pipe was put into service at the middle of March, 1906, and has been in continuous use up to the present date, having carried approximately 100,000 tons of dry pulp during that time. Careful measurements of the interior diameter of the pipe, made at the expiration of 13 months of service, show that it has undergone no appreciable wear. The total cost of maintenance and up-keep during the 13 months has been 3.57 pesos, spent for paint on one of the viaduct towers. There has been absolutely no other item of expense since its installation.

The pulp is that resulting from crushing through a mill of 80 stamps with a steel wire screen of 26 mesh with 28 wire followed by tube-milling of a portion of the coarse product such that after removal of 38% of the pulp as slime, 52% of the balance nominally passes a 120-mesh screen. At times, however, when the tube-mill has been out of service for replacement of linings, we have run two weeks at a time on straight 26-mesh battery-pulp. On two or three occasions, by reason of neglect on the part of the Mexican in charge of the de-watering cones, the thickness of the pulp has been considerably increased over the normal 4 to 1 proportion and on such occasions a slight deposit of coarse sand in the pipe has occurred, which always gives notice by a whistling noise at a blow-hole intentionally placed in the pipe about 1,000 ft. from its head. This notice always occurs in plenty of time for the error in the thickness of the pulp to be corrected; on two occasions this occurred on night shift and the line filled approximately half-full with coarse sand, but an hour's time was sufficient to clear the line (by the introduction of more water at the head) with no expense beyond the momentary delay. As soon as rifles of sand are formed so as to cause an obstruction in the flow, the pipe develops hydrostatic head above the point of obstruction sufficient to force the sand through. Delays from this source have not caused more than four hours' loss of time in the entire 13 months, and even then they were due to carelessness at the cones, as above mentioned. Normally, month after month, there was not the slightest tendency of the pulp to deposit any sand whatever in the line and

when, due to electric shut-downs or any other stoppage at the mill, pulp ceases to flow into the head of the pipe, the line keeps itself entirely clear without the introduction of water.

At the present capacity of 250 tons per day the pulp runs only $1\frac{1}{4}$ in. deep on the bottom of the 8-in. pipe, running at such speed that the distance between the ends of the line is traversed in about 12 minutes. The additional 80 stamps to be started in September will double the amount of pulp, but the pipe can carry 1,000 tons as easily as the present 250.

The wear is so slight as to be invisible up to date, but in any case, the pulp running only in the lower part of the pipe would allow of the turning of the entire line five times before it was entirely worn out, and we figure that if the line were to become worn out every two years it would only mean two cents per ton carried. The present appearance is that it will last 50 years.

C. W. VAN LAW.

Guanajuato, July 2.

Cyanidation in the Transvaal.

The Editor:

Sir—I must take exception to your Johannesburg correspondent's remarks in your issue of June 8. Possibly he does not understand the matter he criticises, otherwise it is altogether difficult to understand why he should so strongly depreciate the work of the Denny brothers because the local people are apparently unable to estimate accurately the assay-value of their ore.

That the "new metallurgy" consisted merely of a method of assaying is news to me. What the Messrs. Denny announced was that:

(a) The old method of treating coarse sand by a long percolation was wrong in theory and in practice and that in spite of opposition the mines would abandon it in favor of fine grinding, for which purpose they introduced tube-mills.

(b) By the use of tube-mills they expected to obtain not only a higher extraction from the resulting finer grinding, but also a higher output.

(c) A continuous method of slime treatment by having solution occur during the flow or travel of the pulp instead of in special agitators after collection and settlement was cheaper, both in first cost of plant and in working, than the prevalent decantation method.

In order further to increase their extraction they employed filter-presses instead of decantation.

All their points the Messrs. Denny appear to have proved to the hilt. Indeed, the use of tube-mills, starting from the one imported by the Dennys, has now spread all over the Rand; and I note no fault whatever is found with the extraction obtained by the "new metallurgy," and that in the same speech Mr. Albu apparently states his satisfaction with the work of the filter-presses. His one cause of dissatisfaction seems to be his difficulty in obtaining reliable preliminary assays; but this surely should not be insuperable, and is an entirely subordinate matter to the obtaining of the highest proportion of gold at the minimum cost.

I write this because the remarks of your correspondent are calculated to convey a wrong impression, and not because I am entirely in accord with the line taken by the Dennys. They were cautious in their preliminary work on tube-mills; their verdict was amply justified by results. They did a good deal of preliminary work with filter-presses; there, too, their decision seems justified by results. Whether they displayed the same caution in building two new plants depending on solution of the gold by what we may term 'mortar-box contact' would

be a much more debatable subject except for the fact that it appears they provided additional plant for the purpose, but the use of which was not found in practice to be necessary, and I have been advised—not from many source connected with the Messrs. Denny—that Mr. Albu has strongly objected to the expenditure of the money on this precautionary measure, though the vats have been converted to other use.

It looks, therefore, not merely as if the Messrs. Denny have proved their case to the hilt, but that indeed this same system has been adopted in practically all the latest American plants and in a number of those in other territories. To my mind a serious matter against the new system is the difficulty of copper-plate amalgamation. In Australia, pans are successfully used for the purpose, and I have no doubt that other suitable methods will be devised in plenty—possibly by the use of some special alloy for amalgamating plates—now that the need of special effort in this direction is known; but I cannot believe that a method of extracting all the gold in the slime at practically no expense for plant (as far as the solution of the gold is concerned) will be lightly abandoned by the industry (I do not refer here to South African practice only) merely because of a faulty or ineffective method of obtaining preliminary assay-values. The saving in cost of equipment alone is a factor compelling most serious attention.

In conclusion, I am not prepared to admit that the Messrs. Denny have yet made out their case in favor of all-sliming. If the words "finer grinding" are substituted for "all-sliming" there would be general agreement with them, but personally I am of opinion that it is still the most satisfactory and economical method in general practice—with exceptions—to percolate in vats, without expense for power or handling, all the sand suitable for percolation in vats, the remaining pulp receiving the suitable treatment necessary. Apart from the less cost of thus treating the fine sand, we have as yet no reliable data to prove that the extraction obtained from slimed sand, as sand, apart from slimed concentrate or slime, is so much higher as to justify the extra cost of sliming and of handling the slime. There may be ores in which total sliming is preferable, but where the gold is carried in the concentrate or in contact with some softer or more fragile material it is surely cheaper to treat the fine particles of sand without subjecting them to the partially unrecovered expense of further grinding.

ANOTHER CORRESPONDENT.

London, June 26.

A Fundamental Problem.

The Editor:

Sir—May not the difficulty which your correspondents encounter in getting explicit reports from professional mining engineers, and which they attribute to 'hedging,' be partly due to the fact that they expect from us more than we can possibly give? Too often what clients really want is somebody who can see into the ground; and they end by employing the man who can humbug them into thinking he can do it. Let me illustrate:

Some years ago an old gentleman who employed me to make an examination of a 'prospect' in which he had become interested, and which had not opened up as well as he had hoped or been led to expect, found fault with my report. He said, "This report of yours is very interesting, and no doubt very profound; but it does not tell me what I want to know. I want you to tell me in one word, yes or no; is this a great mine, or is it a damned swindle?" Unfortunately I could not answer him that way; it was neither.

So with the rest. They want reports which are emphatically black or emphatically white; but the facts, three times out of four, are neither black nor white, but gray. Great mines are few and far between; and we do not often get called upon to examine them; "damned swindles" are more plentiful, but the promoters generally take good care that honest engineers do not get called in to pass on them. Most often we meet with the 'prospect,' which may or may not ever make a mine. The chances are always against it; but if there were nobody to take chances there would soon be an end to mining. The people who employ us are usually not content with simple advice to speculate or stay out, as the case may be; they say they want the facts, and will decide the rest for themselves. But the sober facts seem to them lacking in definition; and your employer thinks you are hedging, whether you advise him to plunge or not.

GEORGE E. COLLINS.

Denver, July 5.

THE manner of converting iron ore into malleable iron has undergone many changes. It is made from the pig in the bloomery fire or in the puddling furnace, generally the latter. The process consists in melting the pig metal in a reverberating furnace where the flame is made to act directly on the metal, keeping it exposed to a great heat and constantly stirring the mass, thus bringing every part of it evenly under the action of the flame until it loses its remaining carbon. It then loses its fluidity and is formed into a puddler's ball. This is the point or connecting link between cast and malleable iron. The operation of puddling is a most important one, as the quality of iron depends so much upon the skill with which it is conducted. After the puddler's ball has been formed it is passed to a heavy squeezer or steam hammer, the object being to press out the liquid cinder which the ball contains when it is ready to be rolled or hammered. While hot it is generally passed between the rolls and drawn into a bar about 5 in. wide and 3 in. long, which is called a muck bar. To prepare bars for the refining operation they are cut into such lengths as are best adapted to the size of bar or sheet required. The sheared bars are then piled one on the other, according to the quantity of metal necessary to make the finished piece. They are then brought to a welding heat in the heating furnace and passed between the finishing rolls until drawn to the proper size.

JAPANESE CEMENT COMBINATION.—It is reported that a scheme to form a syndicate among cement companies is under consideration among cement manufacturers in Japan. The object of the scheme is said to be to improve the quality of cement, and to check the import of the foreign article. The Okayama, Saga, and Mie cement companies have agreed to incorporate with the Toyo Cement Co. All the companies mentioned are paying fairly good dividends. Upon the completion of the organization of the new company, cement works will be established in Manchuria, and in the northeastern part of Japan.

GALVANIC ACTION sometimes weakens steam boilers. Water is distilled in a steam boiler; therefore it is broken up into its constituent parts, namely, two parts of hydrogen and one of oxygen. In a boiler made of iron with brass trimmings, the iron becomes the positive pole, and in this connection it is well to remember that brass is composed of copper, zinc, and tin, and some of it may contain about 85% copper, thus doing good work as a conductor of electricity. This explains why boiler inspectors are not very enthusiastic in recommending brass feed-pipes and water-column connections.

Some Ore Deposits in the Inyo Range, California.

Written for the MINING AND SCIENTIFIC PRESS
By JOHN A. REID.

The Inyo range, with the White mountains, its northern continuation, is the first ridge east of the highest portion of the Sierra Nevada. It is separated from the latter by Owens valley. There exist ore deposits in this sierra that possess some unique characteristics.

The structure of the Inyo range, simple in broad outline and very complex in detail, is that of a monoclinical fold modified by faulting and igneous intrusions. In certain portions the monoclinical character approaches that of an overturned anticline with axial plane pitching downward to the west. Intense faulting, both of large and small movements, is everywhere present, and plays a vital part in the genesis of the orebodies. In general, the planes of motion are of two series, parallel and transverse to the range.

In the immediate vicinity of the mineral deposits the sedimentary rocks embrace Paleozoic (probably Carboniferous) sandstone, shale, and limestone. Intruded into these are two varieties of igneous rocks, of different ages. The older occurs in dikes and stocks, varying in width from 3 to 100 ft. or more, near the axial plane of the range. On the mining ground these dikes show a rock containing a large proportion of perfectly formed zoned crystals of plagioclase set in a blue-gray ground-mass. The ground-mass is too fine to be resolved entirely by the unaided eye, but shows flakes of biotite, and needles of hornblende in a feldspathic paste. Pyrite is present, but it is largely, if not entirely, secondary. This rock will be referred to as a porphyritic diorite, no microscopic examination having been made. North and south of the ore deposits the porphyritic aspect of the dikes passes by gradations into the normal granitic rock of dioritic appearance composing the larger intrusive masses. The essential minerals are hornblende and plagioclase, with accessory orthoclase, quartz, and biotite. Microscopic investigation may prove the stone a granodiorite or a quartz monzonite. The later intrusive occurs in dikes from 3 to 30 ft. wide, none of which, in the mining ground, reach the surface. The color is a medium dark blue-gray, and the grain fine. Well developed crystals of hornblende, plagioclase, and quartz appear in a finer network of feldspar crystals. In some dikes at a little distance from the mine openings, the rock gradates into a hornblende andesite, or the 'porphyrite' of the older classification. It will be referred to as a quartz-diorite. On the low western foothills of the Inyo range is a large dike of andesite parallel to the axis of the mountains. As far as known it has no connection with ores of any sort.

In the mine openings the older dikes of porphyritic diorite strike parallel to the crest of the range and dip west about 50°. The most important one lies between the limestone on the east and the shale on the west, though near the surface the rocks are badly jumbled. (See Fig. 3.) The other dikes of porphyritic diorite cut the shale. All invariably show the effects of intense dynamic action, and are frequently reduced to the consistency of putty. It is often found that cross-faults, and even quartz veins, and quartz-diorite dikes fail to cross them, and cease upon reaching the semi-plastic material of the porphyritic mass. The strongest quartz vein opened underground wedges out entirely upon meeting the largest of these dikes; their prevailing western dip in the interior of the great fold probably indicates that they were intruded before the completion of a part at

least of the folding. If this be so, and the rock be correlated with the dioritic intrusions of the Sierra Nevada, the present Inyo range is of early Cretaceous age. The later dikes of quartz-diorite strike northwest-southeast, and stand vertical, usually cutting the porphyritic diorite. This stone is commonly fresh, even though badly faulted in the immediate vicinity of the orebodies.

The structural details surrounding the mineral deposits are vitally important. Four faults, or groups of faults, of earlier age than the ores, are found in the mine workings. Two of these, about 300 ft. apart, are of the more important series of north-south movements; the other two, separated by about 900 ft., are east-west cross-fractures. The former stand nearly vertical; the latter dip both north and south. (See Fig. 1.) The eastern and the northern faults are the two larger. Many post-

Fig. 1.

mineral north-south fractures are exhibited in the various openings underground.

The orebodies are of three distinct types: in order of relative importance they are: (1) Those deposited in spaces caused primarily by intersecting faults; (2) quartz veins filling fissures; and (3) contact deposits in the limestone near the dikes of porphyritic diorite. There is a slight contact zone along the quartz-diorite dikes. Each orebody not a quartz vein shows characteristics of both first and third types. There is a genetic relationship with the two intrusive rocks.

The largest orebody, as well as the most peculiar and interesting, was formed at the intersection of the east and the north faults. The first stands vertical; the second dips south at an average angle of 45°, steepest near the surface. The shoot therefore pitches to the south. The spaces opened by the two movements were greatest toward the surface, due to the fact that given forces of disruption will produce greater visible effects under a lighter load near the surface than at greater depth. Further, because of the later age of the east-west frac-

ture, and a quartz-diorite intrusion nearly parallel to it, the opening along this fault becomes relatively more important in the lower part of the orebody. The quartz-diorite dike cuts the intersection of the two fault-planes 600 ft. below the surface. The form of the orebody may be compared to that of a short piece of tapering pipe flattened at the big end in one plane, and at the small end in a plane at right angles to the first. The length downward along the pitch is 800 ft.; the thickness in a north-south line at the surface is 200 ft., while at the downward end it is two feet; the width at the surface is 20 ft., increasing below to 75 ft. (See Fig. 2.) From the 600-ft. level downward the orebody continues as a contact seam on the north wall of the dike; above this level the seam leaves the intrusive and follows upward the intersection of the two faults. The minerals were deposited not only at the actual intersection, but also in both fault-fissures near-by, to the greatest extent in the larger north-south opening. A cross-section of the deposit is of the shape of a cross with unequal arms. (See Fig. 1.) The ore is an argentiferous galena, with small amounts of antimony as an impurity. It occurs in nodules in altered limestone, some of which, extracted in the past, are reported to have been 4 or 5 ft. in diameter. Cerussite and anglesite invariably surround the sulphide. The only gangue is calcite, or marbleized limestone; quartz is notably absent. The lead in an oxidized condition does not penetrate the surrounding rock for more than the fraction of an inch; the silver exists in an undetermined form at considerable distance from its original position. In the lower portion of the deposit the silver shows evidence of existing in proportionately greater amount than the lead.

The second type of ore deposit is found best developed in the limestone along the foot-wall of the easterly dike of porphyritic diorite. The contact formation always accompanies the dike, but bears ore only where enriched at cross-fractures. The ore of the contact zone proper is pyrite, now found only as limonite, either in large masses or in pseudomorphs after the sulphide. Gold is contained in small amount. The more valuable mineralization is due to the presence of both sets of faults. The west north-south fault cuts this contact within the mine openings; much movement near the dike, and in the dike itself, has occurred, and the largest orebodies were formed at the intersections of the two east-west planes of fracturing with the contact and the north-south fault. Small nodules and lens-shaped masses of argentiferous tetrahedrite with some quartz, similar to that of the quartz veins next described, are found irregularly distributed along the plane of north-south motion. The second orebody in importance in the mine was formed at the north intersection of cross-faults, though the deposit at the south intersection may yet prove the more valuable. (See Fig. 1.) The ore in this latter orebody shows a considerable percentage of bournonite, the sulphantimonide of lead and copper. Argentiferous galena is the chief mineral in both deposits. The length north and south is a few hundred feet; the thickness is from 1 to 10 ft. Dikes of quartz-diorite are near.

The third type of ore deposit, the quartz veins, is that which has furnished the rich silver ores of the Inyo range. These veins are narrow, from one to four feet wide, and are remarkably irregular in local dip. The dip in general is nearly vertical, or about 85° north, but in detail only a zigzag line could represent it. The strike is northwest and southeast. The effects of faulting are less shown on them than on the other deposits. The most important mineral is tetrahedrite, often the argentiferous variety freibergite, and always containing some silver. Arsenic, lead, and zinc occur in small quantities.

Other minerals are galena, sphalerite, and in some veins chalcopyrite. All were deposited simultaneously. Azurite, malachite, smithsonite, and calamine occur in irregular masses in the limestone adjoining the veins. A little linarite has been reported. A number of the sulphantimonides of silver and copper may also be present; the complete mineralogy of the ore is not yet worked out. The only gangue of the veins is quartz.

The lead-silver ores are genetically connected with the intrusions of the quartz-diorite. The solutions set in motion by them found open channels at intersecting faults, and deposited therein their mineral contents. The largest orebody, described first, shows a small contact seam on the north wall of the dike proceeding upward, and opening out into a large orebody above. Further, this contact seam is well developed only where the dike is near the two systems of intersecting faults. At the time of the deposition of the lead-silver ores the ground was badly fractured outside the main faults, so that small amounts of ore can be found scattered in many places, particularly near the surface. The quartz veins are of later age, though from the facts that they strike and dip nearly parallel with the quartz-diorite dikes, and that there is some similarity between their ore minerals and those of the other deposits, it is thought that they may represent the last effects of the dioritic intrusions. The silicious solutions in small quantities penetrated many lesser fractures, as along the east dike of porphyritic diorite.

The relative ages of the three types of deposits are clear. The contact zone accompanying the porphyritic diorite is oldest. A period of north-south faulting followed, accompanied by east-west movements. The subsequent intrusions of quartz-diorite caused more fracturing, chiefly in an east-west direction, and initiated the deposition of the lead-silver ores. The quartz veins, containing antimonial and sulphide ores, filled fissures formed probably as the last results of the dioritic igneous activity. The absolute ages of the deposits are less apparent. The main contact formation is probably early Cretaceous; the quartz-diorite, with its associated ores, probably, is of early Tertiary age, synchronous with the early andesites of the Sierra Nevada; the quartz veins are but little later than the lead-silver minerals.

Not the least striking feature of the orebodies not quartz veins is the variation of richness with depth. In the lower portions of the deposits there is an absolute decrease in both lead and silver values, but a relative increase of silver over lead. A question now beginning to evoke more and deserved attention is the deposition of minerals in vertical range. In the continuous opening of the largest orebody the rich ore of the higher levels gives place to very low-grade material at the bottom. The galena is practically lacking near the dike, but there are several ounces of silver. The limestone of the Inyo range is noted for similar examples, those seen being small. A typical one is shown in Fig. 4. Here a small, but continuous seam in the bedding planes of the country rock, about an inch thick, is barren of all but decomposed calcareous minerals stained by iron. A few vugs containing calcite crystals show themselves. At the top, on the surface of the ground, is a nodule of solid galena, locally (and appropriately) termed a 'blossom.' The galena is tightly held in the limestone with no decomposition products surrounding it. The fissure leading up to the sulphide apparently stops at that mineral. Not sufficient study of the characteristics of the lead deposits has been made to warrant a truly scientific statement of cause. The facts known are as follows: The lead ores are genetically connected with the dikes of quartz-diorite. Most of these dikes fail to reach the surface. In the

eases observed the ore-bearing fissures are barren of lead minerals near the intrusive, and rich near the surface of the ground. Silver, when present, is in relatively greater amount near the igneous rock.

To sum up, the Inyo range exhibits three distinct types of mineral deposits: Those at the intersections of cross-fractures and containing lead-silver ores; ordinary quartz veins carrying antimonial and sulphide ores of copper, lead, silver, and zinc; and contact deposits showing chiefly iron ores, with traces of gold. The lead-silver ores are genetically related to the dikes of quartz-diorite, and the quartz veins are of a slightly later age, probably connected with the last stages of the expiring igneous activity of the early dioritic intrusions. The relative ages of the deposits are, from earliest to latest: (1) Contacts between limestone and porphyritic diorite; (2) lead-silver ores; (3) quartz veins. The geological ages range probably from early Cretaceous to early Tertiary. The Inyo mountains are notable in the large number of ore deposits, and should eventually become an important mineral region.

MALLEABLE CAST IRON is iron which when first made is cast in the condition of cast iron, and is made malleable by subsequent treatment without fusion. Although the

COAL SUPPLY OF THE ORIENT.—The coal supply of the Far East at present is secured in a large measure from either India, Australia, or Japan, but there is prospect that within the next few years the competition in the coal markets will be much keener if the coal fields in

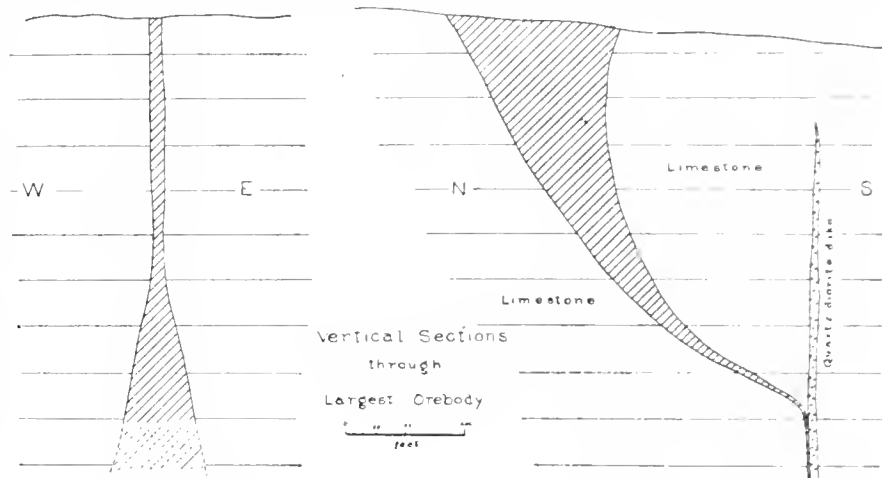

Fig. 2.

the Malay Peninsula, the Philippines, and China in any measure come up to expectations, and sufficient capital is made available for their development. In the Philippines the coal fields of Batan island on the east coast and the large area awaiting development in Cebu are attracting the attention of American capitalists and already the Philippine Government is considering the development of the Batan mines, while the railroad companies have been looking over the deposits with a view

Fig. 3.

Fig. 4.

English name of this variety suggests that it is cast iron, it is not truly a variety of cast iron, but rather forms an independent species of iron, because it lacks the essential property of cast iron, which is its extreme brittleness. Though the term malleable castings is common, the term malleable cast iron is very rarely used.

to securing their coal supply in the islands. With what success these fields may be worked is a matter of some little conjecture. Reports of discoveries in Manchuria of coal deposits and the fact that engineers are going over all the ground carefully would indicate that there is prospect of unusual development during the next few years.

Concluding Notes on Guanajuato.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

At Guanajuato, it is estimated that it takes 2 to 2½ Mexicans to do the work of one capable white miner, but the native is paid one-fifth the wages given to the other. The Mexicans are undersized, they have the physical proportions of an American boy. In the mountainous regions, as in Durango, the men are bigger and stronger, and on contract work they can earn twice as much as the Guanajuatenses. Owing to *fiestas*, it is found that in employing a gang of *peones* on such work as excavation, it is necessary to carry 100 men on the payroll in order to have 30 always available, that is, they work one-third time.

In drilling a 'down' hole, there is no difference worth mentioning between white and native labor; the Mexicans strike the drill 100 times per minute, and their short rapid blows will equal in final effectiveness the long body swing and harder blow, made one-half as fast, of the European or American. The Mexicans work in less space. I have seen 18 men working in a shaft 7 by 15 ft.; there were nine pairs, one man holding the drill and the other striking, the change of one to the task of the other being made with the celerity characterizing a drilling contest. They carry water for the hole in their mouths and squirt it out as it is required.

Like the Turk, the native Mexican is a great porter. In carrying weights, the load is hung by a rope attached to a head-piece (*mecapat*), which is a nearly oval mat made of the *istle* fibre; it takes the shape of the forehead, and almost down to the eyes, lying over the front hair and under the hat. The *tenateros*, or ore-bearers, can carry eight *urobas* or 200 lb. apiece; they will transport as much as that 100 ft. up the stone stairways of the old mines. At the Prospero mine, each man carries four tons per shift a vertical height of 75 ft., and a length of 400 ft., at a cost of 50 cents. At Guanajuato I saw some excavating for foundations done at 12 cents per cubic metre, the rock being carried a distance of 200 ft. across the gravel of a *barranca*.

They are good blacksmiths. At the Peregrina the native workmen took out the flues from a boiler that was in bad repair; they cut the tubes at both ends, and welded on an extra piece to make the original length. One smith and three helpers welded 24 tubes in 12 hours. The native blacksmiths are good drill-sharpeners, though better at shaping than at tempering.

Guanajuato had a flood, and like that of Noah it serves as a new starting point in local history; things happened B. F. or A. F. The catastrophe occurred on the first and second days of July, 1905, so that the recollections of it were still vivid at the time of my visit. Unusual tropical showers poured upon the neighboring country, and the waters converged from a steep watershed into a narrow ravine choked by bridges and crowded with dwellings. Never wide, the bed of the Guanajuato river had been elbowed by roads, houses, and debris, so that in places there was left a channel only two metres deep and four metres wide. Furthermore, it was extremely tortuous, the original course of the river having been repeatedly diverted to secure space for buildings. On the first day, the water rose to a level which just exceeded that of the flood of 1873—about four feet above the street. On the second day the volume of water was doubled, it rose 15 to 17 ft. above the pavement, and made terrific havoc among the soft masonry and mud walls of the old town, which melted like salt before the onrush. A few minutes sufficed to cause the collapse of many buildings, and to create fearful con-

fusion. At that time a sewer was being constructed at the upper end of the town, near the Presa, and the timbers of this were torn out, to be carried forward so as to form a battering ram, demolishing the *adobe* walls and choking the confined channel of the torrent. Officially it is stated that 54 were killed, but 73 were carried to the morgue, and it is probable that fully 100 people perished. Many Mexicans from the outside country happened to be visiting the town, it being the time of a *fiesta*, and of these a number were never accounted for. No Europeans or Americans were drowned.

At the time, there was nothing humorous about the disaster, but, with that happy instinct of humanity, as the horror was forgotten, some of the absurdities were remembered. To the natives it was an opportunity for spoil; looting was general. "*Es un regalito de Dios á*

After the Flood.

nosotros que no sabemos trabajar”—“it is a little gift from God to those of us who don't know how to work,” so they said to themselves. Some of the *peones* laid their hands on a shoe-store that had been devastated, and to this day they can be seen wearing a tan shoe on one foot and black leather on the other. The pink and green steamer-trunks of an American lady glorified the torrent for awhile, they bobbed under the arch of a picturesque bridge, and landed in the second story of a needy native. A mule was borne by the flood into another second story, and in his terror he bit into a box of ivory soap, and it was this that buoyed him across the waters. Billiard tables, with their slate tops cruelly exposed, were engulfed in the whirling debris. Seventeen pianos and two canons meandered down stream to the sound of many waters and their own spontaneous accompaniment. An azure splendor suffused the scene as a box of bluing from a laundry made its vivid passage, whereupon the pianos played a familiar waltz of Strauss. Bolts of silk

appeared among late mules and defunct pigs, street-cars were seen with men balancing on their unsteady decks until the upper windows of a church offered shelter. The Teatro de Juarez received a complement of burros, and the compliment of their lamentations, which simulated grand opera, just as the sequel imitated Noah's Ark, for when the waters subsided, they made their timid descent down the grand staircase with all the dignity befitting a momentous occasion. But worse things than these happened; a case of Saratoga whisky floated onto the desk of a total abstainer—and the owner of the whisky never saw it again.

With the downpour of rain came darkness, the natives lit candles, and the women came out on the balconies with lights, wherewith they made the sign of the cross, the church bells were rung, and to the natural horror of the scene was added a touch of solemnity. This was on the first day; when the second flood came in the late afternoon of the second day, with its repetition of an uncanny darkness, the people crowded to the adjoining hilltops, which were brilliantly illuminated with moving candles, while the air vibrated to ten thousand bells. To them it was the end of the world, and we, of San Francisco, who saw a greater devastation, can well imagine that to their simple minds it seemed a horror beyond explanation.

And so I come to the end of the notes that record my recent travels in Mexico. To speak in the language of photography: I brought some films from Mexico; most of them were only snapshots, there being no opportunity to get time exposures, therefore the images that I have delineated, and the impressions that I have tried to convey, may lack definition. But beyond the mental imprints that it has been my endeavor to transfer to the pages devoted to this account of a journey in the southern land, I brought other memories and experiences, which were never developed; they remain blurred, and to none but myself have they a meaning. I have recollections of multi-colored façades, of sunlit walls and cool *patios*, the sound of bells, and the crackling of whips, cries of *cerreza* and *frijoles*, conical hats and hooded women, a stream of chocolate colored humanity, a politeness that gave dignity to the commonplace, a squalor that soiled romance, and a sunshine that glorified everything; and then, like the refrain of a song that we love, the kindness of the men of my own race, and the hospitality of women who make every abiding place a home. And so, *Adios; vayan con Dios mis amigos.*

THE BOUNDARY BETWEEN STEEL AND IRON.—It would be well to decide on a definite carbon-content to serve as a boundary line between ingot iron and ingot steel, between puddled iron and puddled steel, and between any other varieties of wrought iron and weld steel. Two plans have been considered. One is to draw this line at 0.32% carbon or its equivalent in other elements, for the reason that this carbon-content appears to correspond to the critical point *O* in the diagrams of Roberts-Austen and Roozeboom. This has the merit of corresponding to a definite physical boundary. Mr. Pourcel would classify solely according to the presence or absence of slag, so that 'steel' should include all forms of iron freed from slag by fusion and cast in a malleable condition, and 'wrought iron' should include all classes produced in a pasty condition. He does not think that any cross classification according to the proportion of carbon is expedient. The other plan is to draw the boundary at 0.20% carbon, because this is a convenient place to separate the important classes 'soft steel' and 'half-hard steel' so that if this point were adopted

'ingot iron' would be synonymous with 'soft steel,' and 'ingot steel' would be the equivalent of the two classes 'half-hard steel' and 'hard steel.'

A New California Map.

A broad desert valley, through which a sluggish river flows, walled in on both sides by rugged mountain ranges whose peaks tower thousands of feet above, is the striking feature presented by the map of the Mount Whitney quadrangle just published by the United States Geological Survey. Few of the maps issued by the Survey can be examined with greater interest, since few areas within the United States comprise greater variations in topographic forms than the 960 square miles there delineated.

The Mount Whitney quadrangle is a part of east-central California and includes portions of Inyo, Tulare, and Fresno counties. It is crossed in a general south-east-northwest direction by Owens valley, with Owens river hugging the east side and discharging into its sink, Owens lake, in the south-eastern corner of the area.

On the east, Owens valley is bordered by the Inyo or White mountains, a typical desert range, with a number of peaks over 11,000 ft. high, with no perennial streams, and with few springs. These mountains, however, contain valuable mineral deposits, which are mined at a number of places.

Along the west side of the valley stretches the Sierra Nevada, presenting to the east an abrupt, almost precipitous wall rising from a height of about 4,000 ft. to over 14,000 ft. in a distance of less than five miles, and topped by the highest peaks in the main body of the United States. Mt. Whitney, named from J. D. Whitney, former State Geologist of California, rises 14,501 ft. above sea level, and closely rivaling it in height, Mt. Williamson attains 14,384 ft. Six other peaks in this region are over 14,000 ft. high, and there are many that fall just below that height. The numerous high peaks and glacial gorges and the thousands of little lakes that diversify the rugged west slope of the Sierra are famous summer camping grounds for Californians. Across the northwestern corner of the quadrangle winds the south fork of Kings river in a gorge 1,000 ft. deep, while in the southwestern part of the area Kern river traverses its wonderful canyon.

Owens valley is a barren desert except where reclaimed by waters entering it from the mountains, and Owens lake contains so much soda that its extraction has been found commercially profitable. The river itself for many miles above the lake is also saline, but the numerous streams that drain the west slope of the Sierra carry fresh water in abundance. The valley is traversed by the Nevada & California Railroad, a narrow-gauge line that will probably soon become part of a trunk line connecting the goldfields of Nevada with Los Angeles. Another connecting link with the city of Los Angeles will be formed by the pipe-line that, taking water from Owens river near its head, will pass along the west side of the valley, tap all the mountain streams that it crosses, and finally deliver its supply to the city. This gigantic enterprise will be accomplished at a cost of \$23,000,000.

The various natural and cultural features of the region are shown on the map with as much fidelity to detail as the scale, one inch to two miles, permits. Valleys and peaks, lakes and rivers, settlements and isolated houses, roads and trails are accurately recorded, and there is even marked, on the southeastern corner of the sheet, the fault-line resulting from the great earthquake of 1872.

The Dome of Equilibrium and the Caving System of Mining.

Written for the MINING AND SCIENTIFIC PRESS
By CLAUDE T. RICE.

The basis of successful underground mining is a thorough knowledge of how to open up the orebody. To acquire that knowledge, one must have a fairly good conception of how different ores and rocks are affected, when stopes or openings are made in them. And yet in regard to this very little has been written, in fact, practically no published data exist on the subject.

While much time is devoted by mining engineers to studying the geology of different districts and mines, they appear too busy to devote much study to the principles underlying this abstruse, but important, subject of how to support underground openings. The mining geologist aspires to understanding finally the how, whence, and wherefore of ore deposition from the study of nature's past. While volumes are written on such matters, the vital and ever-present problem of how to keep the stopes open, while getting the ore out, is conspicuously avoided in mining periodicals, so that we have made but little advance since Philip Deidesheimer invented the square set.

The mining engineer in general pays no attention to the problem of supporting mine openings. He depends upon the foreman for this, as well as for most of the other fundamentals of getting out the ore; and as for the foreman—well, he has acquired his knowledge by years spent in the stopes. Generally his knowledge is in many respects so nearly instinctive that he is unable to impart it to others. As a result of this ignorance on the part of the mine superintendent and the inability of the foreman to transmit his experience, although mining has advanced much in many directions, in this particular one it is still in much the same position that it was forty years ago.

At first the way to mine was to employ plenty of timber. Then, as the indiscriminate use of timber began to deforest the eastern part of this country, the mining men of the Lake region, under the spur of the ever increasing price of timber and the fact of the steadily decreasing value of their ore, faced the problem. Instead of spending money upon timbers, they decided to let the ore cave, and thus was evolved the admirable caving systems, so characteristic of certain of the iron ranges. But the Western engineer, owing mainly to the value of his ore, is, in general, unable to use a caving system. In consequence, the problem of keeping his stopes open gains in importance as with the diminution in the supply of timber.

At first all the members of the square sets were sawed timbers, and the posts were of ordinary length. As economy became necessary, the first step was to increase the length of the post, but owing to the inconveniences attending the use of posts of excessive length, the limit of saving in this direction was soon reached. As another step in economy, mines situated near a timber-supply substituted round timbers for the sawed, these being framed similarly to the square ones. Finally D. W. Brunton, realizing how much of the strength of round timbers was lost by such framing, devised his system of bevel framing for the round timbers composing the square sets, and the end of the road is approached in that direction of saving.

Other engineers, notably those of Utah, with mines situated far from a timber supply, stuck to the square timbers, but made a saving by varying the size of the different members of the square set, until the girts, posts, and caps are not of the same cross-sectional dimen-

sions. Thus we see that all are realizing the increasing importance of the problem. They are all trying to save; they save as much in the timber bill as they dare. But still it is the same old rule of guess that dictates the size of timber put in the stope. We have advanced from the days of the Comstock, when metallurgy was so much in the hands of the slick 'process-man,' purely by trying to find the why and wherefore of things. Yet in regard to the mechanics of underground stoping we are as much in the dark as formerly; cannot this be remedied?

This subject of the mechanics of underground stopes can hardly be studied as a problem in pure mathematics, but it is to be approached by an inductive attitude. At present few engineers would care to predict definitely—or even approximately—the shape that the roof of a stope, so many feet long and so many feet wide, would have in a certain kind of rock. Yet nature solves this problem every day. Geology, chemistry, and physics have accomplished much by the patient study of nature's own way of solving her problems. Cannot the mining man also hope to accomplish something by similar patient study in the direction indicated? Paradoxical as it may seem, we can learn most about this subject in those mines where the stopes are not supported, that is, where the caving system is used.

As is well known, untimbered stopes cave until they assume a self-supporting arch or dome-like shape. This 'dome of equilibrium' is not reached immediately, but is approached by a series of alternate falls of rock, first in the centre (the key of the arch), and then on the sides. The roof of the stope remains firm as long as the load upon it is due to that stope alone. But, as other stopes are opened near-by, the forces acting upon the roof become more complex. No longer is it the simple scaling or caving stage, but, owing to the changed nature of the forces, the movement becomes more block-like and the subsidence assumes the character of a fault. Instead of the steady load of the rock's weight, which alone is acting in the case of the simple stope, there are sudden stresses, due to the caving of other stopes, thrown upon the roof. These sudden stresses do not give the roof time to adjust itself by caving until a new dome of equilibrium is assumed, but instead the strength of the rock is suddenly exceeded, and new slips and joints are formed irrespective of those previously existing. The movement has reached the faulting stage.

This last dislocation is the one that sends its effects even to surface. It is this final stage of movement that causes the subsidence at surface characteristic of certain mining districts. Because of the thickly populated condition of some of the mining districts in their country, the colliery engineers of England, France, and Germany have made careful study of this faulting stage, and several articles upon it have been contributed to the mining societies of Europe.

Many writers have assumed that a stope will cave until it fills itself, but to me this view, except in the case of 'running ground,' seems hardly tenable, for, in what few caved stopes I have subsequently entered, I have always found an open space between the arched roof and the pile of caved rock. In general such a large stope-opening is necessary before caving commences; the self-supporting dome is assumed before the stope fills itself. The caving action is progressive, and as the slabs accumulate in the stope, they so support the sides that caving ceases. Finally, owing to the weakening of other stopes, the faulting stage is reached; not until then does the opening become completely filled.

In supporting the roof of a stope, only that portion of the roof that is below the line of the dome of equilibrium

requires support; the rock above this dome sustains itself. If, therefore, the shape of this dome of equilibrium in each kind of rock were known, it would be easy to calculate the weight of rock hanging below the dome, and so timber the stope as to hold up this weight. I am under the impression that the shape of this dome is fairly constant in each kind of rock; especially in the same rock in the same district. Of course, slips and joints, sudden changes in chemical composition, the dip of the strata in sediments, and many other facts, would affect the shape of the dome, but as long as these were small their effect would also be small. If investigation of the shape of this dome should suggest any formula to determine the strength of timber necessary to support the ground below the dome, the effect of these joints, etc., could easily be included by the factor of safety used.

Possibly I have allowed my enthusiasm to get the better of myself in this matter, but I hope not. I firmly believe that if mining men will only enter upon a study of the shape of the dome that caved workings assume in different rocks; if they will only plot the general shape of this dome and note the effect of slips, etc., on its shape, as shown by comparison of sections taken in different directions through the dome, together with whatever other phenomena that appear important; if then they would contribute these notes to some mining periodical, such as the *PRESS*, I believe that sufficient data would in time be accumulated to determine approximately the shape of dome to be expected in different rocks.

The possibility of placing the subject of supporting underground stopes on some approach to a scientific basis would seem to warrant a trying out of the above suggestions. Haphazard methods, such as have prevailed before, have led to little advance in the knowledge of this subject. Is it not a matter of sufficient importance to deserve a systematic study? Little can be accomplished by one person, but if a general interest is aroused much can be hoped for. Again I wish to suggest that the desired data are most readily obtainable at mines using the caving system.

In another article I hope to show what an effect the idea of this dome of equilibrium may have upon such a standard method as that of mining with square sets.

THE advance of prices abroad of articles imported into the United States, recently noted by the Bureau of Statistics of the Department of Commerce and Labor, seems to have occurred largely in manufacturers' materials, and, in a more limited way, in manufactures, while foodstuffs show little advance and in some cases a decline. The advances in prices shown in these principal articles imported, comparing average prices in the 10 months ending with April, 1907, with those of the corresponding months of 1897, are as follows: Pig tin, an advance of 207%; copper in pigs, bars, ingots, etc., 127%; unmanufactured fibres, 117%; iron ore, 108%; shellac, 107%; raw cotton, 69%; lumber, 64%; hides and skins, 63%; india rubber, 59%; raw silk, 57%; wood pulp, 56%; wool, 32%; nitrate of soda, 31%; and pig iron, 22 per cent.

CHINA'S COPPER SUPPLY.—The Chinese Government realizes the great demand for copper that exists by the provincial mints for the manufacture of bronze coins of different denominations, and that, up to the present, China depends upon foreign supply. It has therefore been decided to appoint a special high commissioner who is to reside in Yunnan, the great copper-producing province, and who will also have jurisdiction over the mines of Kiangsi, Kuangsh, Hunan, and Hupoh.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The green mineral sent from Temecula, Cal., by C. L. B., is Malachite.

The mineral marked W. L. P., Ketchikan, Alaska, is Calcite.

A fragment of Hornblende was sent from Glendale, Ariz., by V. E. M.

A specimen of Quartz carrying sulphides was sent from Metcalf, Ariz., by W. P. L.

D. H. C., of Guadalajara, Mexico, sent a fragment of Specularite. It is a valuable ore of iron if found in sufficient quantity.

The specimens marked R. H., West Jordan, Utah, are: No. 1, Cuprite, Malachite, and Chrysocolla; No. 2, Pyrite and Chalcopryite.

The four specimens of rock sent from Lucin, Utah, by A. E. P., are: No. 2, black Slate; No. 3, Calcite and Limonite; No. 4, Mica Schist; No. 5, indurated Sandstone.

The Mexican burro is an animal which, in spite of its lowly condition and almost poetical patience, has played an important roll in the commercial life of Mexico as one of the means of transportation of merchandise. The traffic between railroad stations and interior points must still be handled by burro transportation. While the ox cart is in use in many parts of the country, the burro is much the swifter carrier, and is also an important factor in the mining industry, chiefly as an ore carrier. In the cities he serves in a variety of capacities. An animal of average weight, 500 lb., will carry in the neighborhood of 220 lb. and travel an average distance of 36 miles per day. Very few burros are sold in the City of Mexico, the principal market being in the States of Guerrero, Hidalgo, Puebla, and Oaxaca. Prices vary from \$12.50 to \$17.50 United States currency, and in the City of Mexico a burro trained to certain work will bring an average price of about \$20. The burro is raised almost solely for home use, there being very few exported, and these going to the United States and Cuba.

THE commercial utilization of various grades of oil as fuel for generating power, regardless of whether under steam boilers or in internal-combustion engines, will be easier, so far as technical difficulties are concerned, the better it can be ignited and the more efficiently it can be burned. Thus gasoline is a fuel of the greatest possibilities for automobile purposes. It is obvious, however, that in addition to the above other considerations are to be made when deciding the question of applying a certain fuel to certain uses, such as price, danger of explosion in handling, respective heat value, and, before all, heat density, that is, the quantity of heat contained in the unit of volume.

RUSSIAN GOVERNMENT MINES.—According to statistics of the treasury department in the Russian Empire, 15,072 oz. of gold was produced in 1906 in the Tomsk mining district, against 16,236 oz. in 1905. The Siberian steppe mining district produced 12,981 oz., against 9,852 oz. in 1905.

The Electrical Smelting of Iron Ore.

Written for the MINING AND SCIENTIFIC PRESS
By R. L. PHELPS.

It was only a short time ago that the first smelter for the electrical reduction of iron ore by the Héroult process was erected at Sault Ste. Marie under the auspices of the Canadian Government. The success attendant on this experiment in the East suggested to H. H.

Fig. 1.—The Héroult Furnace, in Course of Construction. Charging Tubes Not Shown.

Noble, president of the Northern California Power Co., the possibilities of such a smelter for the reduction of iron ores found on the divide between the Pitt and McCloud rivers in Shasta county, California. The idea seemed feasible, particularly on account of the economic advantages offering themselves in this vicinity. Adequate electrical power could be obtained from the lines of the Northern California Power Co., running within a mile of the deposit, a plentiful supply of first-class limestone adjoined the iron ore, and unlimited timber was available for making charcoal. The chief uncertainty lay in the fact that at the Sault the smelter was operated with a single-phase alternating current, and in Shasta county the power available was three-phase 60-cycle alternating. The character of the current was

such that it was feared trouble might occur through short-circuiting between the three electrodes that would have to be employed in a three-phase system. As there had been no previous experiments with three-phase currents in a smelter of this design, the engineers naturally took special care to prevent any possible short-circuit. It was suggested that division walls might be constructed between the electrodes in the furnace, but these walls would reduce the capacity of the furnace. As stated, Mr. Noble decided to install a Héroult electric smelter to treat the Pitt river deposits, the experiment being

made entirely at his own personal expense. A suitable site was chosen on the Pitt river about six miles from its confluence with the Little Sacramento river, and about eight miles from the town of Kennett on the Southern Pacific railroad. Since construction began on the smelter the broad-gauge railroad of the Sacramento Valley & Eastern has been commenced from the Bully Hill copper smelter to the Southern Pacific railroad. This railroad passes the Héroult smelter so as to afford an outlet for the product, as well as convenient transportation of supplies to the smelter. Arrangements were made with C. B. Morgan, of the Shasta Iron Co., for a supply of ore from the Pitt river mine. This ore is magnetite; an analysis of about 400 tons at the smelter gave the following results: Fe, 70.2; SiO₂, 2.4; insoluble, 2.8; S, 0.012; P, 0.01%. It is interesting to note the small percentage of sulphur occurring in the magnetite as compared with the heavy sulphide copper ores of the Iron Mtn. and Mammoth mines only a few miles away. The deposit of magnetite occurs as a big mass, 100 to 250 ft. wide, following the contact between diorite and limestone; it is seen on both sides of a steep ridge and has evidently been exposed by erosion.

The method of mining is by quarrying from the side of the deposit facing the McCloud river. The face of ore now exposed is about 250 ft. high. A quantity of ore has been brought by wagon from the mine to the smelter, a distance by road of three miles; later, a surface trolley tramway 5,000 ft. long will be constructed around the side of the mountain to a point on the ridge directly behind the smelter, the ore being taken thence to the smelter itself by an aerial tramway 3,000 ft. long, as is indicated by a dark line on the photograph of the smelter site shown in Fig. 2.

The erection of the smelter and necessary buildings has been superintended by N. Petinot, an experienced

Fig. 2.—Electrical Smelting Plant on the Pitt River.

mechanical engineer. Paul Héroult, the inventor of the method of electrical smelting, has arrived to witness the experiment. He is accompanied by Robert Turnbull and E. Humbert.

The smelter is housed in a concrete and structural steel building covered with corrugated iron to insure strength and protection from fire. The sketch of the floor plan of the smelter will give an idea of the arrangement of the water-cooled step-down transformers that deliver to the electrodes 30,000 amperes at 50 volts 60 cycles from the 22,000-volt potential of the power trans-

mission line. Connection from the transformers to the electrodes is made by copper and aluminum buss bars through apertures in the concrete partition wall separating the transformer-room from the furnace and flexible bare copper cables lead the current from these terminals to the water-jacketed electrode-holders.

The smelter itself is elliptical in form with one compartment standing about 5 ft. high, made of heavy sheet steel, and lined inside with the best magnesite brick. The bottom of the furnace is formed of heavy cast-iron plates with a covering of tamped carbon to form the neutral

the top cover of the furnace, as shown in the drawing. These tubes consist of an inner tube made of steel and an outer tube made of cast iron so as to leave an annular space large enough to serve as a conduit for the gases that are generated. Bunsen burner slots are provided in the base of each outer tube to allow enough oxygen to enter, in order to complete the combustion of the gases liberated from the charge. The burning of these gases in the annular space heats the charge as it is fed through the inner tube to the furnace, thus delivering the charge hot instead of cold. The inner tubes pass to the

point of the circuit. The bottom plates are insulated from the upper parts of the furnace with asbestos. A tap and trough are provided on one side to draw the molten pig iron onto the molding beds. (See Fig. 1.) Owing to the small amount of slag produced in this furnace it is not necessary to provide a tap for removal of the slag. Any slag produced from the charge is exceptionally beneficial in this process as it offers an efficient resistance medium. The practice is to keep the electrodes in the slag rather than in the molten metal, the result being a better quality of product. Through apertures in the top cover, the three carbon electrodes are introduced; these carbons are 18 by 18 by 72 in. and were made in Sweden. They are fastened by wedges to a copper holder, which is water-jacketed, and by mechanical means these are lowered and raised from the furnace when necessary. Four combination charging and draft tubes are placed on

charging floor above the smelter. The gases are drawn through a chamber under this floor to the stack and the inner charging tubes are continued through the floor.

The charge is made of charcoal, limestone, and ore. The charcoal is burned in kilns close to the plant. The heat for smelting the ore is obtained from the resistance of the slag and charge to the current as it passes from the electrodes to the neutral point; consequently at the start the electrodes are in slight contact with the neutral bottom of the furnace. As the charge becomes heated the electrodes are drawn out of the molten iron and remain in the slag and charge.

Water for cooling the water-jacketed transformers and electrode-holders is furnished by an 8-h.p. centrifugal pump.

The current was turned on for the first time on June 29 to dry the lining and test the electrodes. At this trial

American carbons were used, but they cracked under only partial current pressure, and Swedish carbons were thereupon substituted. At the time the failure of the first lot, obtained from Cleveland, was imputed to their exposure to rain, but on inquiry it has been ascertained that the Swedish carbons were several months older and had been exposed to the weather fully as much.

On the evening of July 3 the current was again turned on and the furnace warmed up for the formal start on the morrow. About 10 o'clock on July 4, the furnace being sufficiently heated, a charge was added and the real experiment began. The daughter of Mr. H. H. Noble had the honor of feeding the first shovel-full of ore. With a low steady hum of the current the smelter ran successfully for 3½ hours, reducing the charge until molten iron collected in the bottom. This proved that the furnace could be operated by a three-phase 60-cycle alternating current. At the end of 3½ hours difficulty was found

with the centrifugal pump, which refused to deliver enough water to keep cool the transformers and electrodeholders. Fearing a possible rupture of the entire electrical system through the overheating of the transformers, it was decided to shut down the furnace until provision could be made for better service from the centrifugal pump. The furnace had been run long enough to prove that it was perfectly possible to operate successfully on a three-phase system, and also that enough pig-iron had been smelted to prove the feasibility of the electrical reduction of the Pitt river magnetite.

It was afterward found that the difficulty with the centrifugal pump was due to its position, requiring a long suction-pipe sunk in a rattle in the river. It was suggested that the air in the rattle-water, with the help of the long suction-pipe, probably caused the difficulty. A site for the pump at the river bank has been selected, and the suction-pipe will be sunk in still water. Preparations were being made to operate the smelter again on July 9 to reduce the 100 tons of ore ready for the furnace.

THE process of making cast iron depends much upon the kind of fuel used. Charcoal, coke, bituminous, and anthracite coal are all used, and the quality of pig metal is influenced to a great extent by the kinds of fuel, as well as by the temperature of the blast, with which the ore is reduced. When anthracite coal is used the ore is placed at once in the blast-furnace. When charcoal is used, the ore is first roasted by distributing it in alternate layers with waste coal, wood, or sometimes with charcoal, and the pile thus formed is ignited and burned in the open air. For more refractory ores a kiln similar to that used for burning lime is required.

Alaska Coal Fields.

Of the 600,000 square miles forming the Territory of Alaska, it is estimated that 12,644 square miles are underlaid by coal-bearing rocks—that is, rocks that probably contain coal seams—and that 1,238 square miles contain workable coal, ranging in age from Carboniferous to Tertiary and in composition from anthracite of good quality through high-grade semi-bituminous steam and coking coals and ordinary bituminous coal to lignites of various characters. Many of the known coal deposits are of great thickness, especially where the coal carries a large carbon content; but unfortunately, high grade of coal and great thickness of beds are as a rule accompanied by geologic structure unfavorable to mining.

From the Pacific Coast to Bering Sea and the Arctic slope, through the valleys of Copper and Yukon rivers and their tributaries, coal beds are widely distributed; and although it is unlikely that any except the high-grade coals of the Pacific Coast and the Matanuska and Bering river fields are suitable for shipment far from the mines, many others may be locally of extreme importance and great value.

The coal-mining industry of Alaska is still practically undeveloped, the total production for 1906—the year of greatest output—being 6,660 short tons, valued at \$20,000. The most active mining operations have been on Cook Inlet, in southwestern Alaska, on the Yukon, in Seward Peninsula, and at Cape Lisburne, all undertaken to provide coal for local use, by small coastwise or river steamers, at mining camps and at canneries.

Alaskan coals have in recent years been the subject of a large amount of special investigation by the Geological Survey, and in addition much information concerning coal has been gathered each year since regular geologic work has begun in Alaska, by Survey parties working primarily on other problems. A brief summary of the results of these investigations, illustrated by a map showing the distribution and area of coal and coal-bearing rocks, is included in the Report on Progress of Investigations of Mineral Resources of Alaska in 1906, published by the Survey as Bulletin No. 314.

THE recent advance in Europe of the Thury direct-current system of power transmission demonstrates the fact that unless an alternating-current system approaching it in simplicity of design and economy of material is developed, it is only a question of time before the high-tension direct current will gain a footing upon this continent. Consequently, a high-tension one-phase system having several features not in common with either the direct-current or the three-phase system has been proposed. While the present three-phase system is more flexible than the direct current, it is more complicated, and requires greater outlay for transmission material. The ordinary one-phase system is simpler than either of these two, but requires 25% more copper than the three-phase system and a proportionately greater amount than direct current. Then again, considering the strain upon the insulators as a standard of comparison, the fundamental difference between the direct and alternating-current systems gives the former an advantage that no alternating-current system can overcome.

CORROSION or the wasting away of the iron of a steam boiler may be due to acid in the feed-water. Where sulphuric acid is found in this water its destructive force is often spent in destroying the feed-pipes before it actually enters the boiler. This is expensive, annoying, and even dangerous in some cases, but is much preferable to a boiler explosion.

Notes on Smoke Suits.

Written for the MINING AND SCIENTIFIC PRESS
By an Occasional Contributor.

Within the last few years many of the smelters in the United States have been harassed by suits for damage and injunctions to restrain them from discharging into the atmosphere sulphur and arsenic fumes. In these suits the demand for the injunction to restrain is the *grand coup de canon*. A judgment for damages, if assessed by a court, would, relatively to the importance of the smelting interest, be of trifling moment. The injunction to restrain is, because of there being no practical means known to science for the condensation of the sulphur fumes, of very serious moment, and would, if issued, mean the closing of the smelter.

The damage caused by the sulphur fumes whether slight or serious is, if any, obvious to all observers by its effect on vegetation and is readily capable of proof. Sulphur fumes damage only vegetation. The damage from arsenic and lead is less obvious to the eye. Vegetation is not affected, but herbage on which smelter flue-dust containing arsenic and lead or the condensed vapor of arsenious acid have settled, is cumulatively poisonous to stock. That damage has been caused to stock by metallic poison is less obvious to the eye than that of the damage by sulphur acids to vegetation. It would have to be proved by analysis of certain organs of the dead animals and other evidence. It is possible to diminish (by condensation, cooling, and filtering) the metallic poisons, but it is not practicable to remove the sulphur dioxide, which is not condensible by the foregoing mechanical means.

Cases of damage by smelter fumes vary therefore from the extreme of all sulphur and no metallic poison when the loss is vegetable, to those of little sulphur and much metallic poison when the vegetation flourishes, but the stock feeding upon it is more or less affected.

The party bringing suit against smelters for damage says, like Mr. Dooley: "I don't care who makes the laws, so long as I can make the injunctions." "Injunction or your purse" is the opening of the campaign. Many weak people might be disposed to take an opportunist course and settle for a sum stiff in itself but totally insignificant compared with the loss that would result from a cessation of the smelter operation. The majority knows that such a settlement with a spy would only be to invite attack from the following battalions, so they defend the suit.

Under the old common law there is no defence to a suit for proved nuisance. It must be stopped and an injunction must issue, no matter what may be the consequences to the defendant, or how insignificant the injury. In these days there are many public enterprises and others of public importance that necessarily cause some nuisance or annoyance and the principle of the great benefit has therefore been invoked and very generally admitted.

A railway passing by a stable may by vibration and other nuisance cause nervous prostration to a cow therein. The owner of the cow may demand the cessation of the nuisance and technically relief must be granted to him. But since the damage to the public generally would be enormous by stopping the operation of the railroad, and as the value of the cow is small and can be compensated for the grounds set up by its owner, that the damage is "irreparable" would not be nowadays admitted and he would be given compensation and told to hold his peace.

Smelting is a lawful industry and therefore entitled to the protection of the courts of law, but like similar industries, it must be carried on in suitable localities. There

is no excuse for a glue works planting itself on Fifth avenue, New York, and such works would be quickly enjoined. In cities there are generally districts where such industries can be carried on and the nuisance depends very much upon its situation.

Thus there are two big principles invoked by those defending smoke suits. The greatest benefit to the greatest number, and the choice of a suitable site for the smelter. It is doubtful if today any court would grant an injunction without weighing these two considerations in defence.

We have seen that recently in Utah the court would not admit that the locality chosen by the smelters there was one suitable for such industry. The principle of the greater benefit appears generally admitted. Therefore there are judges who adhere strictly to the maxim "*Sic utere tuo ut alienum non laedas*," but the Supreme Court of the United States has upheld the principle that an injunction to restrain an act, the consequences of which are trifling, will not issue. It must, of course, be shown in defence that the defendant is employing every reasonable and effective precaution known to science to prevent the nuisance complained of—and each case will have to depend upon its merits. We have seen that.

An industry causing more or less annoyance to neighboring proprietors may be maintained in some places and not in others. That is "the suitability of location." That where the injury complained of is not irreparable but readily compensated with money and is relatively insignificant an injunction may be refused. This principle has not been universally accepted.

It is unfortunate that in some cases where one locality chosen for the industry has been the most suitable that could be found, and where the damage was trifling that there has been litigation that has seriously interfered with the smelter industries without corresponding benefit to its neighbors.

It is to be hoped that out of so much litigation there will result some definite establishment of legal principles. If the old-fashioned principle, having still its adherents, that an injunction must issue, no matter what may be the consequences to the smelter or how insignificant may be the damage, should be upheld in the case of the United States *v.* the Mountain Copper Co. by the Supreme Court of the United States, smelting will become a lost art and other methods of reducing ores will have to be employed.

In stating that it is not 'practicable' to condense the sulphur acids, I do not mean that it is not physically possible. It could be done physically, but not commercially. It is therefore impracticable and cannot be done industrially.

The damage done to vegetation by sulphur acids is a question of degree. A few tons of oxidized sulphur discharged into the atmosphere would hardly be perceptible outside the limits of the works. That from a few hundred tons per day would be observed some miles away, and according to the manner of its discharge. If discharged low on the ground its effect is strong in the immediate vicinity. It is broken up by the surface and is quicker diluted, and not felt at much distance. If discharged high up in the air from a stack it may not affect the immediate vicinity at all, but travels much farther and in regular air currents, it is slower in becoming mixed and diluted, and may drop with damaging intensity at a considerable distance from the works. It seems to be more potent in damp than in dry weather. It cannot be condensed by practicable means because sulphur dioxide is not condensible at ordinary pressure and temperature and requires an enormous volume of water

for its collection in solution and this water evolves it on exposure.

In England, chemical works are restricted to a specified intensity, but not quantity. Thus the number of grains per cubic foot of gas escaping is specified, but no limit is put by law on the quantity. Of course, if the quantity were such as to do damage there would be still responsibility though the legal limit had not been passed.

The advantage of this is that as far as Government inspectors are concerned the proprietors know their position relative to the authorities, just as does a motorist; but if the latter, while driving at less than the legal limit, should carelessly or willfully cause damage, he would be responsible for his act.

It would seem that as regards damage at a distance it is better to discharge the smoke in regular quantity low down on the ground from several points. The annoyance locally would be extreme, but that at a distance would be minimized. Discharging at a height, if the smoke contains much sulphur, is apt to cause damage at a distance. The damage from arsenic and lead is often fatal to stock. The fine flue-dust and fume collect on grass on the side facing the smelter and adhere to it. Animals fed on such grass are sometimes poisoned. Such flue-dust can be arrested in the smelter by condensation and filtration.

Notes on the Fundicion Smelter.

This smelter is being erected by the Douglas Copper Co. at Fundicion, 153 kilometres from Guaymas. The plant is situated on the east side of the Cocoraqui drainage. A well has been put down on the side of the creek to a depth of 100 ft., and has already encountered an abundant supply of good water. The smelter will be of 600 tons capacity, and is to be, in its design, one of the most modern in all Mexico. The power-plant will consist of Morrison suspension fire-box boilers, each boiler having a capacity of 150 h.p., and built to work under a steam pressure of 150 lb. per sq. in. The blower-engines are tandem-compound, built by the Bates Machine Co., and directly connected to 150-cu. ft. Roots high-pressure smelter-blowers. The generators, two in number, were built by the Western Electric Co., and are directly connected to vertical cross-compound Bates engines. The current will be direct and of two voltages, 110 volts for lighting purposes and sundry other uses, and 500 volts for power-transmission. Engines will be run condensing. All the machinery throughout the plant, including the pumps, will be motor-driven. The furnaces were built by the Power & Mining Machinery Co., and are 41 by 160 in. with 14-ft. charge column. The settlers are of 15 ft. diam. by 5 ft. deep. The furnace connections to the stack are by means of 6-ft. steel down-takes into an 11-ft. balloon-shaped steel-dust-chamber, connecting with the stack base. The stack proper is a self-supporting steel structure, having a lower diameter of 12 ft., and an upper diameter of 8 ft. The total height of the stack will be 177 ft. above the ground-line.

Material will be delivered to the charge-floor by means of Jeffrey steel-pan roller-bearing elevators, each having a capacity of 25 tons per hour. The material will be run into the elevator-boots in divisional charge-cars, which provide for the delivery of the material in proper proportions. The discharge from these elevators will be into steel bins placed one at each end of each furnace, from which the charge will be run into the furnace direct. The mixing of the charge will be secured through its dumping into the elevator-boots, its passage up the elevators, its dumping into the bins of the furnaces, and

from there into the furnaces. So far as it is known this is the first instance of this arrangement in connection with a smelting plant, and it is believed that it will effect a more thorough mixing of the charge than any arrangement in use elsewhere.

The sampling of the ores will be done mechanically. One-tenth of the total tonnage will be cut out mechanically by means of a Vezin automatic sampler mounted on trucks. These samplers will have a capacity of 30 tons per hour. This one-tenth, which will be the sample proper, will be sent in a narrow-gauge car to the sampling works, where it will pass successively through the crushers, rolls, and samplers. These last machines will cut out two equal portions of one-hundredth each, and these two portions will pass through the finishing department of the sampling works as independent samples, and from there go to the laboratory. This practice will give a thorough check both on the sampler and on the laboratory work, and will make difficult either an attempt at a fraud or an undiscovered inaccuracy.

The service of the plant throughout will be by means of a 36-in. gauge railway; all material will be moved by locomotives, including the slag and matte. The matte ladles will have a capacity each of ten tons, and will be mounted on 36-in. gauge trucks. The converter-building will be 200 ft. from the furnace-building. This arrangement will make the working conditions for the men in both of these departments far better than they would be if both departments were combined.

The principal source of ore for this plant will be the properties of the Douglas Copper Co., all of which are in the district of Alamos, the El Cobre mines being the best known. The company has been developing that property for the past four years. The development work has been extended to a depth of 900 ft., and to a length along the vein of half a mile. The engineers of the company have estimated that there is ore in reserve on that one property sufficient to keep the plant in operation for five years.

By September the company will be in the market for the purchase of ores carrying gold, silver, and copper. The magnitude and the mechanical equipment of the plant will be such as to enable the shipper to accompany his carload of ore to the smelter, see it sampled, and get his results in from one to three days. This advantage to the shipper will be apparent when it is borne in mind that sometimes there is a lapse of from four to six months in securing settlements on ores shipped from the West Coast to smelters in the United States, and to the interior of Mexico.

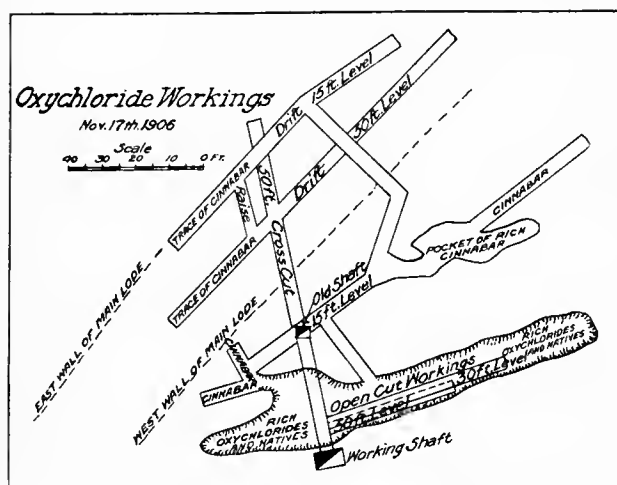

YUKON ENTERPRISE.—An important work contemplated in the near future is the construction of a large power-house of approximately 1,000 h. p. near the western boundary, on the Yukon river, some 50 miles below Dawson, for the purpose of furnishing electrical power to dredges on the Fortymile creek and its tributaries in Alaska and the Fortymile and Klondike rivers in Yukon Territory. The company has a power-house in Dawson and furnishes this city and Grand Forks with electric light, and Dawson with water for household purposes and a hydrant system for fire purposes. The fuel used in their present plant is coal taken from the company's mine on Coal creek, at which place the proposed plant is to be situated, the idea being that it is cheaper to convey electricity than coal. The output of the mine last year amounted to some 8,000 tons, the entire output being used by the company in Dawson. This coal landed at Dawson by the company's steamer costs about \$12 per ton. With the plant at the mouth of the mine the coal costs about \$2 per ton.

Rare Mercury Ores.

Written for the MINING AND SCIENTIFIC PRESS
By CLIFFORD G. DENNIS.

At Terlingua, in Brewster county, Texas, there is an interesting deposit containing oxychlorides of mercury. The ore carries terlinguaite, eglestonite, montroydite, and calomel in a blanket formation between layers of limestone. There is, however, a fine fracture, now filled with calcite, that seems to have afforded a passage between the layers of limestone.

The first discovery of this prospect was a thread of calcite in the hard limestone. Upon following this veinlet down a few feet, eighteen to twenty inches of earthy

Plan of the Mine.

formation was encountered; this was very rich in terlinguaite. The layer of earthy material spread out over an area of about 15 by 100 ft., being cut off completely at each end and at the sides by hard massive limestone. Going down into the lime again a few inches, another stratum of ore was discovered of slightly smaller dimensions; this one and the many lower strata were not as thick as the upper one but there was alternate lime and ore until a depth of 20 ft. was reached, here a more massive limestone was encountered, which later development proved was the lower limit of the mineral-bearing earthy material.

In taking out these layers of earthy material, caves were often found in the lime with crystals completely coated by terlinguaite; some of the caves were half full of native mercury, while others were as full of calomel. The lining of these caves yielded beautiful specimens; in some fragments of cave-lining there were white crystals, the points of which were tipped with a coating of terlinguaite or eglestonite, while in the base of the crystals there occurred native quicksilver in an amalgamated mass that would flow but not disintegrate.

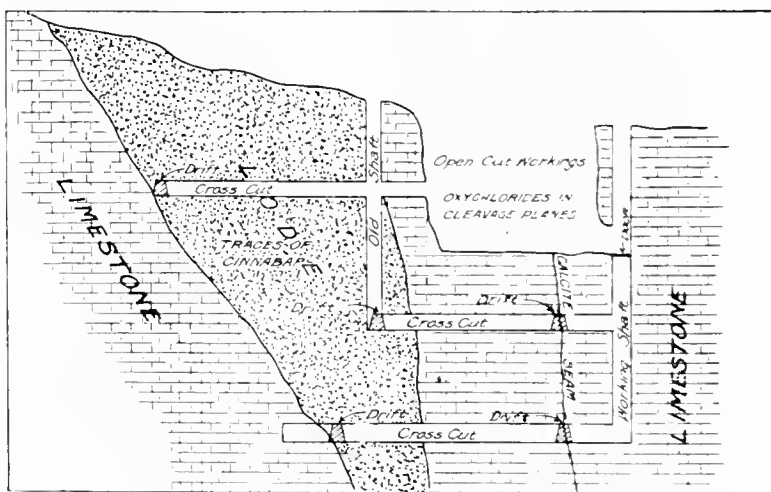

As mentioned, this deposit does not occur as a well defined vein but (as seen by the accompanying sketches) it lies adjacent to an extremely strong lode that is traceable for long distances on either side of the deposit. There seems to be no connection whatever between this lode and the oxychloride deposit although it probably received its enrichment from the lode by erosion and oxidation.

To facilitate mining, a shaft was put down on one side to a depth equal to that of the open-cut. This shaft was

subsequently continued to a depth of 50 ft., where cross-cutting and driving were started on the calcite vein of the oxychloride deposit and on the main lode. The drift at this level failed to find any oxychlorides, so another cross-cut and drift were run at a point 15 ft. higher and above a layer of very hard limestone that the shaft had penetrated. In this upper drift some native mercury was taken out but not much of anything else. Evidently this hard layer of lime prevented the solutions from penetrating below, for even the calcite vein was much weaker below this point and sometimes the fracture was barren even of calcite.

Strange to say, development in the lower workings on the main lode failed to discover anything more than traces of ore, in the form of cinnabar; not a trace of oxychlorides was ever found in the main lode.

MINERAL RESOURCES OF THE PHILIPPINES. — The minerals of the Philippines are coal, iron, gold, and copper. Since the American occupation, American miners and prospectors have been busy and more has been learned of the mineral resources of the islands than in the whole previous course of its history. Important deposits of coal have been found at Batan, and asbestos at Ilocos Norte, while gold, silver, and copper have been found in paying quantities. The native workings of some of the mines run back to a remote period, but were primitive in operation. At Batan bituminous coal has been discovered in quantities and of excellent quality. Analysis shows it to be superior to Pacific and Alaskan coal, and equal to Japanese and Australian coal. Tests made on Government transports show it to be slightly inferior to Japanese coal as regards steaming radius, ton for ton, but superior in every other quality of a steam coal. It contains little ash and little sulphur, both of which are present to a much greater extent in Japanese coal. Iron is plentiful. In Bulacan province there are mountains mainly composed of iron, assaying up to 63% and over. Gold is found all over the islands, but as yet in no large amounts. American miners are, however, prospecting the country in their search for the precious metal, and it is believed there are possibilities in this line. Copper is

Cross-Section of the Deposit.

found in large deposits, but lack of transportation facilities has prevented much development.

An estimate of the value of the exports from the United States of iron and steel for the fiscal year ending June 30, 1907, places them at \$175,000,000. As showing the rapid growth of the iron and steel works it may be stated that the exports in 1887 were only \$16,000,000 and in 1897, \$57,000,000.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

MEANS FOR SEPARATING OR CLASSIFYING ORES.—No. 856,612; Herbert E. Wetherbee, Cleveland, Ohio, assignor of six-twentieths to William Rattle, one-eighth to James F. Leitch, and seven-fortieths to Cyrus W. Merrell, Cleveland, Ohio.

In means for separating ores, the combination of a stationary receptacle provided with openings for the ingress and egress of liquid; a positively-driven rotary member in said receptacle which is separated from the receptacle's walls by an annular space forming a sorting column, said rotary member being adapted to impart a rotary motion to the receptacle's contents and to receive and project the ores to be separated into said sorting column intermediate of the top and bottom of the latter; and a source of liquid supply adapted to furnish a stream of liquid flowing upwardly through said sorting column from such ingress opening.

ROLLER MILL.—No. 855,602; Julius Wüstenhofer, Dortmund, Germany.

A roller mill comprising in combination, a driver provided with chambers, a plurality of rollers, in each of said chambers being mounted several rollers, a grinding mantle having a grinding surface, a casing to which said grinding mantle is fixed, floats secured to said casing, means for rotating said casing and grinding mantle, a hollow shaft carrying said driver, a hollow shaft coaxially arranged with said first shaft and supporting said casing, an outer case inclosing said casing and means for feeding the articles to be ground.

ROCK-CRUSHER.—No. 857,940; Edward A. Hoff, Milwaukee, Wisconsin.

Means for producing a gyratory motion, comprising a pivotally mounted shaft, a series of toggles connected with the shaft, a stationary support to which the toggles are connected, and means for moving the toggles successively for causing them to exert pressure upon the shaft in different directions.

CARRYING-ROLL FOR BELT CONVEYERS ETC.—No. 857,610; Raymond W. Dull, Aurora, Ill., assignor to Stephens-Adamson Mfg. Co., a Corporation of Illinois.

A carrying-roll for belt conveyers comprising, in combination, an arbor, and a bar bent to helical form spaced apart from the arbor and forming the periphery of the roll, the ends of the bar being intumed and secured to the arbor.

PULVERIZING OR GRINDING MILL.—No. 857,932; James W. Fuller, Jr. Catasauqua, Pennsylvania.

In a pulverizing or grinding mill, outer and inner casings, rotatable blades or wings arranged centrally in the mill within a casing arranged inside of said inner casing and forming by the operation of said blades or wings the suction chamber of the mill and said outer and inner casings forming separating and collecting chambers, said inner casing provided with a ring adjustably supported therefrom and adapted to increase or decrease the outflow of material from said separating into said collecting chamber.

ROCK-DRILL.—No. 858,495; John B. Marshall, Broken Hill, New South Wales, Australia.

In a rock-drill having a valve, a piston having an annular recess for controlling the operation of the valve, said recess comprising spaced annular grooves and a tapered portion connecting the grooves, whereby to operate said valve with a gradually increasing velocity on the outward stroke of the piston.

Centrifugal Pumps.

The increasing demand for a centrifugal pump of high mechanical efficiency, at a moderate price, has led The American Well Works, of Aurora, Illinois, to specialize in the manufacture of this kind of machinery. It is common practice with many manufacturers of pumps to advertise a certain efficiency as being guaranteed to users of their machines. As a matter of fact there is a vast difference between mere efficiency, and mechanical efficiency. The former means nothing, as it does not take into consideration power consumed, while the latter term means what per cent the water horse-power (power represented in work

done) bears to the applied horse-power. The 'American' pumps are built with especial attention to a high mechanical efficiency, and the manufacturers claim 60 to 68% mechanical efficiency, at the economical capacity, on the No. 5 and smaller sizes, and 70 to 80% on No. 6 and larger; and a mechanical efficiency at 66% under or over-load, of 35 to 59% on No. 5 and smaller, and 50 to 60% on No. 6 and larger sizes. These results are without parallel in centrifugal pump history, and they mean that American pumps use power nearly in proportion to the work done, which is certainly an important consideration. These pumps were designed to elevate water up to 65 ft., but the company builds single pumps of special design to elevate 125 ft., or multi-stage pumps for lifts up to 250 ft. The illustration shows Type I, a high-pressure, two-stage, belt-driven, designed for heads of 250 ft. or less.

The American Well Works is building pumps especially adapted to meet various demands. For irrigation work, for handling liquids containing solids in suspension, for colliery and excavating work, for dredging, for fire protection, for water-works, all these requirements are being studied and met by this company, and on all products turned out, a mechanical efficiency of 25 to 33% greater than that of any other pump manufactured, is claimed.

Trade Treatises.

THE WESTINGHOUSE ELECTRIC & MFG. Co. issue a reprint of an excellent article by Charles V. Allen on 'Electric Machinery for the Operation of Mexican Mines.'

THE THEW AUTOMATIC SHOVEL CO., of Lorain, Ohio, has issued Catalogue No. 6, on 'Steam Shovels.' The pamphlet illustrates and describes shovels, excavators, and dredges, for mines, smelters, blast-furnaces, ore-docks, and various uses.

THE INGERSOLL-RAND CO., New York, issues a handsomely illustrated bulletin on Crown pneumatic hammers. Every detail of construction is shown and every operation described. The design of this hammer is new and the construction simple. It is claimed to strike a harder quicker blow than any other, with 20 to 30% less air and with slight cost for repairs. Made in five sizes for chipping, calking, sealing, flue-heading, etc., and in four sizes, long stroke, for driving rivets from the smallest up to 1½-in. diameter.

Books Received.

'West Australian Metallurgical Practice.' This is a reprint of valuable articles appearing in the monthly journal of the Chamber of Mines of Western Australia. The book contains details of practice and other information of undoubted value to those engaged in cyaniding gold ores. The price is 21 shillings, and the cost in America allowing for custom dues and expressage, will be \$7.

'Hydrometallurgy of Silver.' By Ottokar Hofmann. This book deals with a special subject and it has been prepared by a specialist. The chloridizing roast of silver ores and the extraction of the metal with sodium hyposulphite is a process not so common as it was twenty years ago, but it is still important. The book also deals with the Augustin, the Ziervogel, and the cyanide processes as applied to silver ores. It is well illustrated. 340 pages. Price \$4. For sale by the MINING AND SCIENTIFIC PRESS.

'Water-Works Management and Maintenance,' by Winfred D. Hubbard and Wynkoop Kiersted. This is a valuable work, containing 420 pages and many illustrations. The book is divided into three parts, dealing with the methods and principles of developing, improving, and storing water-supplies; maintenance and operation; and the questions of franchises, water rates, and depreciation resulting from deterioration of physical property. Published by John Wiley & Sons, New York. Price \$4.

'The Engineering Index Annual for 1906.' Size 9½ by 7 in.; pp. 416. Price \$2. This volume represents the continuation of the work originally started by the late J. B. Johnson in the Journal of the Association of Engineering Societies in 1884, and turned over by that association to *The Engineering Magazine* at the close of 1895. The previous volumes, published respectively in 1892, 1896, 1901, and 1906, covered with increasing care and thoroughness the field of technical engineering periodical literature, and in the present volume every care has been taken to maintain and advance the standard set by its predecessors.

'Tin Deposits of the World.' By Sydney Fawns. This is the second edition of a book published by *The Mining Journal*, London. It has been in demand, as affording a compendium of information on a subject, the interest of which has been heightened by a favorable metal market. The book gives an account of the deposits of tin ore in different parts of the world, a description of tin dressing, assaying, and smelting, together with statistics of production. As the only book on an important subject, this second edition is most welcome. It is neatly bound and printed, and contains a number of useful sketch maps and illustrations. Price, 15 shillings. For sale by the MINING AND SCIENTIFIC PRESS.

Commercial Paragraphs.

ANNOUNCEMENT is made by the WESTERN ENGINEERING & CONSTRUCTION Co., Monadnock Bdg., San Francisco, that the contract, which has existed practically seven years, with the Bucyrus Co. of South Milwaukee, Wis., expired July 1, 1907. This contract covered the sole agency for the sale of Bucyrus placer mining machinery and also an exclusive right for the construction of dredges carrying the Bucyrus Co.'s machinery. The company still represents the Robins Conveying Belt Co. The scope of their business is now enlarged so that they are in a position to act as consulting engineers, and are free to construct dredges for the recovery of gold, using not only the machinery of the Bucyrus Co., but also that of any other manufacturers that their clients may specify. They also handle other engineering installations, as the equipment of belt-conveyors and other labor-saving machinery. More attention is now being paid to engineering consultation work by a competent staff of engineers. The personnel of the Western Engineering & Construction Co. still remains the same: F. W. Griffin, pres.; D. P. Cameron, vice-pres.; M. E. Griffin, sec. and treasurer.

Editorial.

WE GIVE an excerpt from the bulletin entitled 'The Juneau Gold Belt, Alaska,' recently issued by the United States Geological Survey. This report by Mr. Arthur C. Spencer is a good example of the excellent work done by the Survey. As it includes a description of the Alaska-Treadwell mine, our readers will find it particularly interesting.

OUR CORRESPONDENT in Mexico refers to the construction of railways in the State of Sinaloa, from the interior plateau to the coast. The Stillwell railroad is progressing steadily. We are also glad to learn that an extension of the Western Railway of Mexico is to be made from Tepehuanes to Culiacan, tapping the Topia mining district. The consolidation of railroad companies under control of the Mexican Government ought to help the mineral development of the country. Certainly, the disorganization along the Mexican Central has been a serious handicap during the past twelve months, and it is much to be hoped that the shortage of cars will soon be at an end.

TO RIDE TWO HORSES is clever, and for that reason we are constrained to admire the agility of *The Mining Investor*, a Colorado Springs paper that attacks pernicious mining schemes, and yet advertises others that look just as bad. The editor deprecates the hypercritical attitude of the technical press, and champions the companies that sell shares in holes in the ground unlikely to become mines. In the last issue some judicious remarks are offered concerning fraudulent mining schemes, and on the same page there stares the reader in the face the offer of a "free trip" to Colorado "if you will get up a club of your friends to take 20,000 shares of the Wellington Development stock at 25c. a share." Does the *Mining Investor* consider this a likely method of making money? Does this look like legitimate mining? Is it business or bunkum? On other pages of the same paper we find offers of other stocks at so many cents per share, coupled with the weird descriptive matter and absurd statements that mark the very people whom the *Investor* attacks on occasion. This giving of advice to investors through the same medium that carries to them the lure of the faker has in it the elements of humor.

Since writing the above we have seen the *Mining Investor* of July 15, which devotes nearly three pages to a patronizing correction of our contemporary in New York. The editor of *The Engineering & Mining Journal* had commented upon the difficulty of educating the public to distinguish between bogus schemes and real mining enterprises. With the views expressed by him we concur. The editor of the New York journal does not need

our aid in defending himself in a pillow-fight with the gentleman at Colorado Springs. But we venture to say that if there is any one that makes it difficult to distinguish between the shadow and the substance, the wild-cat and the mine, the bunkum and the business, it is he of the *Investor*.

The Royal School of Mines.

ENGLISHMEN ought to read the letter from Mr. F. Lynwood Garrison in regard to the Royal School of Mines, because Mr. Garrison happens to be a graduate from the University of Pennsylvania who went to the Royal School of Mines subsequently. As a professional man who has tested the training obtained in his youth, Mr. Garrison is in a position to make useful comment. Evidently this American graduate thinks well of the school to which Huxley lent the lustre of his name and the stimulus of his personality. We confess to enjoying the tilt against the Imperial College with its endowment of red tape and high sounding names, and we appreciate the most un-royal treatment of a great scientific school, rendered truly Royal not by courtesy of the Crown so much as by the kingly men who were teachers of natural philosophy to the youth of England. Our friends of the Institution of Mining and Metallurgy have tried to do their best for the School of Mines and they have succeeded in rescuing it from extinction, but, in common with many others to whom the future of the School is a matter of keen interest, we feel that it is being emasculated by consolidation with such a nondescript university as that of London and with such hybrid kindergartens as the other training institutes at South Kensington. Great Britain controls 70 per cent of the gold production of the world and is directly interested in a mineral output of about \$1,000,000,000 per annum. Nevertheless, there is only one School of Mines of the first rank in the whole British Empire. By the "first rank" we mean an institution comparable with any one of half a dozen schools of mines in North America. We hold it a great misfortune that the great empire-builder, Cecil John Rhodes, was not persuaded to endow the School of Mines instead of Oxford; it would have been more practical and more to the point. For Oxford and the Oxford idea we have a profound reverence, but the sending of Colonials and Americans to "the home of lost causes" is already a magnificent failure. However, that is another story. The one thing beyond argument is the fact that the Royal School of Mines has received scant support from England and its people, until now young Englishmen cross the Atlantic to get the training that is to fit them to become mining engineers. They come so far from home as California. And we do not wonder at it. Dear old John Bull has gone to sleep. He finds the capital for the mines and is surprised if his sons are not as well prepared to manage them as his cousin's children. He thinks that names carrying luminous tails and impressive prefixes can make a Royal School of Mines and he thinks that he strengthens it by calling it an Imperial college—Imperial cheese!

The Cost of Mining.

ON another page we publish some interesting observations, made by Mr. Ross E. Browne, concerning the cost of mining on the Rand as compared with two well known mines in California. Mr. Browne has recently returned from an engagement as advisory engineer to Wernher, Beit & Co. in the Transvaal; so that he is possessed of the best available information on the subject. By a pleasant coincidence Mr. Browne's name is mentioned by our Johannesburg correspondent this week and also by the Secretary of the Interior in an important decision, in respect of the mineral character of land, as reported in this issue. This makes it timely to state that the next State Mineralogist of California will be Mr. Browne, on the resignation of Mr. Lewis E. Aubury, an event that has been expected for six months past and is assured at an early date.

In regard to the cost of mining on the Rand, it is obvious from the analysis presented that the decisive factor is the expense of labor. This is an item too often obscured by those who are enthusiastic over new processes and new machinery. The management of men remains the basic problem in the conduct of any industrial enterprise. While the recent strike at Johannesburg was regrettable, it has had an important result in opening the eyes of the managers of mines to the laxity of supervision and the wasteful methods permitted underground. Once more we see that economy in mining hinges mainly upon getting faithful service from the shift-boss. Those of us who have had charge of mines know how much depends upon the shift-boss. He stands between the technical man and the laborer, between the manager and the miners; he, like a boatswain on a ship or sergeant in a regiment, is in direct contact with the men "behind the gun;" upon his fidelity and sense depends much of the character of the work accomplished. A good shift-boss is worth a lot of money to a mining company. Directors are not likely to know this, nor anxious shareholders, for they come in contact only with the manager, accountant, engineer, and other men at surface. Fine machinery, systematic accounts, elaborate maps, and the like, will impress the non-technical man, who is quite unable to appreciate the relative importance of efficient work in the stope and drift. Mr. Browne makes comparisons likely to provoke keen dissatisfaction among investors in Katfir stocks, for he makes it clear that the cost on the Rand is excessive. Much of this is due to distance from manufacturing centres, the consequent high cost of machinery and supplies, and the big salaries needed to attract capable men so far from home; but this does not explain it all. Lack of economy in management is due largely to poor supervision, especially of the cheap colored labor by the high-priced white overseers. This is one of the penalties of employing the subject races. Europeans and Americans always tend to become lazy when they have coolies at their beck and call. That is the experience with *peones* in Mexico. It can only be overcome by obtaining the service of first-rate shift-bosses and of changing them whenever they become weakened by their environment.

By the Way.

In his presidential address before the Institution of Civil Engineers of Great Britain, Sir Alexander Kennedy said:

In relation to science, I have always claimed for engineers a very high place—a place much higher than some of my purely scientific friends are disposed to allow them. M. Jourdain talked prose all his life without knowing it. So I really believe not a few engineers have spent their whole lives in scientific work while they were nominally only earning their daily bread in ordinary mechanical pursuits. It is not, however, so much that engineering is science as that the scientific spirit is often the basis of engineering, and that when this is the case, engineering becomes as truly scientific as any other branch of exact research, and none the less scientific because it is also the means of making an honest living. Engineering problems differ from ordinary academically scientific problems, partly in that they are much more complex, and consequently more difficult of anything like exact solution, and still more because—exact or inexact—some solution to them has always got to be found.

It has been, no doubt, a source of regret to many who have passed this chair, as it is to myself, that, as years go on and experience accumulates, our work comes more and more to deal with men and matters, with general schemes and methods, even with financial means and possibilities, and less with the directly mechanical problems which fascinated us when we were younger, and for the sake of which, probably, we took to engineering in the first instance. This is one of the penalties of old age—of engineering old age, at all events—and it is no use lamenting it. But speaking of the constructive part of an engineer's work and life, the part on which some of us look back as the very essence and joy of our career, we can see that it consisted essentially of a long series of scientific problems to be dealt with, scientific questions to be answered. If the engineer has dealt with these by scientific methods and in a scientific spirit, if he has carefully marshaled his data, deliberately reasoned from them, recognized where they were incomplete, estimated the probable effect of their incompleteness upon his judgment and upon the result, and finally made his decision and taken his action on the whole matter as a logical conclusion from his previous reasoning, then, I say, the engineer is acting as truly as a man of science as if he were conducting a laboratory research with appliances and methods of exactness and precision unknown in actual professional problems. But a word of caution—unnecessary to the experienced, but sometimes necessary nearer the start. The mere use of formulæ or of exact calculations of any sort is not in itself scientific. That man shows far more of the scientific spirit who recognizes when his data do not allow of the use of any exact formulæ, and who therefore reasons with what may be called mathematical common sense, than the man who tries to force the facts to fit a class-room formula, and arrives at a result which satisfies the formula without recognizing that it bears no relation to the facts. The scientific engineer may use elaborate calculations, or he may not; a most important part of his science lies in judging whether to use them or not. Conversely, the man who calculates elaborately may be working scientifically, or he may not. The mere calculation is not scientific, and in certain cases may only be a cloak to essential defects both in scientific method and in technical perception.

To what extent do engineer and artist come in contact? It can hardly be denied that there are points which at least ought to be points of contact in their work, al-

though their paths seem frequently to intersect rather than to be tangential, and the intersection is too often at ninety degrees! When engineering structures were confined to masonry bridges and pumping stations the matter was comparatively simple. It was difficult to make a stone bridge which was structurally efficient and actually hideous at the same time, and many of the older structures of this type left nothing to be desired by way of beauty of line. Whether a castellated or a quasi-Gothic building was the most suitable form for a Cornish engine-house may be questioned, but at any rate many of the pumping houses which once covered the country were not eyesores, and along with a not unpleasing exterior they combined complete internal suitability. It seems a little odd to us now—but it was certainly prompted by worthy motives—that even the machinery inside the houses was designed on architectural lines which were at least supposed to be lines of beauty. Even in the time of my own apprenticeship, it was universal for bed-plates, entablatures, and other large castings to be finished at their corners and angles with moldings more or less carefully designed according to classical models. Even moving parts, such as the bosses of cranks, were ogeed round their edges, and no connecting rod of a stationary engine was considered finished without a double ogee ring round the middle of its length. Some of these details were survivals from cast-iron construction applied to a forgeable material, but they all died hard, like many less harmless customs. Penn's oscillating engines in the Thames steamers, which were at work until only a few years ago, had their cylinder-cover nuts of gun metal, each made with a turned ogee molding at their base like a fixed washer. And the entablatures of the same engines were wonderful in their wealth of detail. We expect architects to consult and employ engineers to help them over structural difficulties and we may even scold when they come to grief for not doing so. They are, on the other hand, quite entitled to turn the tables on us when they see that an engineer has put up a hideous barn which they could have transformed into a pleasing structure by their own special knowledge, and by that sense of form which it has been their chief business to cultivate, while we have been working at bending moments and breaking loads.

I have spoken of engineering in relation to art; it would perhaps be put down to cowardice if I did not say something of the relation of engineering to nature. Our interference with nature comes practically under two heads—the erection of works for the utilization of water, either for use in cities or for power, and the construction of railroads in mountainous or other beautiful districts. The first is the easier to deal with. The conversion of upland valley bottoms into lakes by the construction of dams seems to me to be out of court at once. I am not inclined to admit that to cover boggy peat land with blue water is doing any harm to nature, or that a fine masonry dam is an eyesore. Moreover, if it is required for the supply of water to cities which could not obtain the water otherwise, it is a "work of necessity and mercy," and there is no more to be said about it, unless the engineer is neglectful. Water storage for power purposes can hardly be put upon quite so high a level, and unfortunately such works are generally accompanied by pipe lines, which, it must be owned, are not things of beauty. But if the net result of the whole is to give employment to hundreds of men in places where hitherto no one could maintain himself, and to utilize natural sources of power hitherto neglected, for doing useful work on the spot where they exist, then I think an impartial arbitrator would say that the schemes were justified, even at the expense of ruling a straight line on the landscape.

Personal.

PHILIP ARGALL is at London.

W. H. ALDRIDGE is at Montreal.

GEORGE W. MAYNARD is at Seattle.

PERCY L. FEARN has returned to New York.

E. C. MILLER has left Ely to go to Hailey, Idaho.

A. W. WARWICK is at Choix, in Sinaloa, Mexico.

JAMES A. FORCE has an office at Tonopah, Nevada.

F. K. BOYD is with the Esperanza Mining Co. at El Oro, Mexico.

W. H. BLACKBURN is with the Tonopah Mining Co. in Nevada.

D. A. CONOLLY sailed from New York by the *Carmania* on July 16.

J. K. ROMIG is manager of the Virtue mine, near Baker City, Oregon.

LEWIS T. WRIGHT is spending a few days at the Iron Mountain mine, Keswick.

E. D. LIDSTONE is general manager for the South Fairview Mining Co. in Nevada.

J. POWER HUTCHINS has been examining mines near Hendersonville, in North Carolina.

E. P. MERRILL is managing director for the Real del Monte Co. at Pachuca, Mexico.

FREDERIC IRWIN is general manager for the Trade Dollar Con. Mining Co. at Dewey, Idaho.

GEORGE H. ENNIS, interested in gold dredging, is in San Francisco from Twin Falls, Idaho.

P. R. WHITMAN is with the Greene Gold Silver Co. at Temosachic, in Chihuahua, Mexico.

C. F. NURSE has accepted an appointment as mine manager in the Ural mountains, Russia.

FRANCIS A. THOMSON is on a tour through the mining districts of East and West Kootenay.

H. A. DENNY, until recently at Johannesburg, is visiting the mining districts of the Western States.

WALTER R. INGALLS, editor of *The Engineering & Mining Journal*, is expected here next week.

R. C. TROGER is general manager for the Estelle Mining Co., at Cerro Gordo, Inyo county, California.

FRANK J. MURPHY, recently in Mexico, is now superintendent of the Yampa smelter, at Bingham, Utah.

C. W. DODGE, JR., is assistant engineer with the Valardeña Mining & Smelting Co., in Durango, Mexico.

CHARLES W. ABBOTT, of Pioche, is assisting C. W. GEDDES in the examination of mines at Goldfield, Nevada.

WILLIAM RICHARDS of Redruth, England, passed through San Francisco on his way from Egypt to Vancouver.

S. A. WORCESTER has completed the installation of machinery at the Findley mine in the Cripple Creek district.

L. A. GREENE, representative of the MINING AND SCIENTIFIC PRESS at Chicago, is on a visit to San Francisco.

C. W. PURINGTON is at the mines of the Ochotsk Gold Mining Co. in Eastern Siberia. He will be there until October.

L. S. AUSTIN will visit the smelters in Utah during August.

THOMAS T. READ, professor of metallurgy in the Colorado College, is spending a month in the San Juan region of Colorado.

J. A. HOLMES, in charge of the Division of Technology for the United States Geological Survey, was in San Francisco this week.

F. W. BRADLEY has left on his periodical tour of inspection to the Bunker Hill & Sullivan mine in Idaho, and the Alaska-Treadwell mine on Douglas Island.

General Mining News.

ARIZONA.

YAVAPAI COUNTY.

(Special Correspondence).—The Unida Mining Co. has just installed a 25-hp. hoist at its mine in the Black Rock district. A vertical working shaft is being sunk to tap the vein at a depth of about 200 ft., from which point driving and cross-cutting will be commenced. The ore now being shipped is coming from a tunnel on the Blue Lead group of claims and is netting about \$60 per ton in gold, silver, and copper, the gold value being \$40 per ton. These claims, known as the Gray Eagle and Blue Nelly, are a part of the property of the Unida Mining Co. Two earloads of timber and lumber have just been received for building bunkhouses and timbering the shaft. Other properties that are making good headway in the Black Rock district are the King Solomon, Black Rock Ltd., and O'Brien. Good ore is being taken from the 160-ft. shaft of the Senator mine in the Big Bug district. The country rock is hard, but an air-compressor is being installed and power-drills will be put in and the work pushed. Tunnel No. 2 is in 260 ft., with some ore all the way, while the last 20 ft. is in good ore, with considerable water coming in. A raise will soon be run to connect with tunnel No. 3, which is now in 420 ft., the first 200 ft. being in a badly broken formation that has only small bodies of ore. At the face of the tunnel a more permanent ore-body has been encountered. About 80 ft. ahead of this tunnel a shaft is being sunk from the surface toward the tunnel-level. This shaft is now down 45 ft. and is in ore of good grade. These workings will be connected as soon as possible. This shaft will not be sunk much farther, as a raise will be run to connect the lower tunnel with No. 2 tunnel and all the ore will be handled from the No. 1 tunnel, which starts at the millsite. A mill is contemplated and may be in operation by October 15. It will consist of a crusher and a battery of Nissen stamps, with a capacity of about 25 tons per day. There are hundreds of tons of concentrating ore on the dumps. The entire cost of shipping and smelting is about \$20 per ton.

Prescott, July 25.

CALIFORNIA.

AMADOR COUNTY.

About 1,500 ft. of development work has been done at the Burlington Gold M. Co.'s property, in the shape of shafts, tunnels, and drifts. The mine is equipped with a six-stamp mill of the individual quadruple discharge type. The company expects to be dropping 60 stamps within a year. The shaft is down 450 ft. and cross-cutting will start at the 500-ft. point. Several shareholders from Michigan and Chicago have recently visited the property.—Some large nuggets have been found at the Gold Top gravel mine at Pine Grove. The company, for which J. B. Batz is the superintendent, has built a restraining dam on the middle fork of Jackson creek.

CALAVERAS COUNTY.

It is reported that the Lightner mine in Angels will soon start on the open-shop principle. It is also unauthoritatively reported that the Utica may start up again on this same basis.

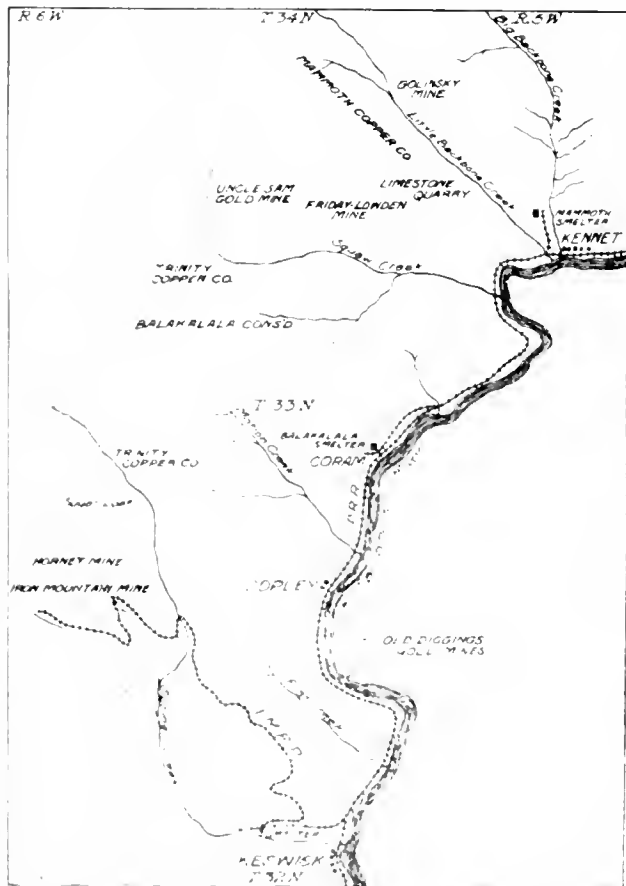

PLACER COUNTY.

The new electric hoisting plant at the Crater has been completed and is running.—Stoping is being done on the 1,100 and 1,200-ft. levels of the Three Star mine and 37 men are employed.—Good ore is being hoisted through the new vertical shaft of the Bellevue mine.—Victor Henderson is taking out good pay-dirt from the Stemple tailing claim in Shirt Tail canyon.—Ed. Witherspoon is opening up the Yankee placer mine, at the mouth of Sailor canyon, on the north fork of the American river.—The new heavy machinery for the Herman mine is being hauled from Colfax. The 12-stamp mill will have 30 stamps added to it. The stoping is at present confined to the upper level, 250 ft. below the surface, and the south drift is being run in the lower tunnel. Dams for power to run the electric gener-

ators will be built on the middle fork of the American river.

SHASTA COUNTY.

Three 50-ton steel ore-cars have arrived at Coram for the Balaklala Copper Co., to be used in hauling ore to the smelter. Four earloads of machinery and a quantity of coke have just been delivered.—A deal for the sale of the Golden Calf mine on Flat creek is being negotiated by Luke and Thomas P. Mitchell. A 615-ft. tunnel has been run on the claim and some ore has been shipped to the smelter that ran \$27 per ton in gold.—J. B. Keating states that cars will be running to Delamar by November 1, over the Sacramento Valley & Eastern railroad that is being built by the Bully Hill Copper M. & S. Co. Two locomotives and adequate rolling-stock have been ordered. The narrow-gauge railroad between the smelter and the No. 3 entrance to the mine, will be made standard-gauge, making the entire road

Map of the Copper Region in Shasta County, California.

18 miles long.—The claims of the Shasta King property are to be prospected by a diamond-drill in charge of D. Longton.—The new hoist for the Shasta King mine is being hauled on wagons to the property.—The Monette brothers have an option on the Brockett mine of the Lower Springs district.—An electric hoist is being erected on the Milton claim, adjoining the White Oak. H. O. Cummins is the manager.—A compressor-plant is to be erected on the Sugar Loaf group of copper claims, where 25 men are working.—The Stauffer Chemical Co. has opened some good chalcopyrite on the Conner claim.—Several tons of pig iron have been drawn from H. H. Noble's electric furnace. This is the first pig iron ever made on the Pacific coast or by a three-phase electric current under the Heroult process. The smelter has been closed temporarily as the Northern California Power Co. can not spare the current necessary to operate it.—L. H. Brown and C. E. Dougherty have recently shipped 50 tons of chromite to the Kennett smelter, to be used in firing furnaces.

SISKIYOU COUNTY.

The Blue Ledge copper mine, in the Elliott Creek district, 30 miles from Yreka, has been sold by W. H. Hamilton, George M. Keller, Marcellus Wenger, J. E. Reddy, and George N. Eiber, to Robert S. Towne & Co., of New York,

for \$200,000. The purchasers have held the property under bond, and have spent \$200,000 in development, running 2,000 ft. of openings. It is thought that a railroad will eventually be built to the property and a smelter erected there. T. W. Carnahan is the superintendent.—The Portland company, working the old Quartz Hill mine, at Scott river, is making some good clean-ups, and a good many large nuggets are recovered.—Some copper ore has been found at Oak Hollow, near Happy Camp, on claims under bond to Fred H. Dakin, Jr.

IDAHO.

ROOTENAI COUNTY.

(Special Correspondence).—The officers of the Green-Monarch M. Co. have been elected. L. H. Jeannot is president and manager, and L. F. Quirk, secretary and treasurer. The company owns a mine on Pend d'Oreille lake, northeast of Spokane.—J. H. Anderson, president of the Panhandle Smelting company, is negotiating with John Humbird for the purchase of \$150,000 worth of timber lands in northern Idaho. The property is along the Pend d'Oreille river and will give the smelter people a complete frontage along the river and far into the interior.—Another strike has been made in the Green-Monarch mine in the Pend d'Oreille district. According to the report it is a continuation of the Cargo strike made last winter. The tunnel was driven off the vein, and when a cross-cut was run, a low-grade ore was encountered when the workmen broke into the vein.—The Pondera Group M. Co., which is doing development work on Pend d'Oreille lake, has installed an air-compressor and a 30-hp. boiler. It has ordered a concentrator for the Climax group of eight claims, opposite Hope. The improvements will cost \$50,000.—Shipments of bullion have begun from the Panhandle smelter at Sandpoint, northeast from Spokane, which was blown in a short time ago. The company has placed an order for a furnace of 125 tons' capacity, to be installed in 60 days. T. L. Lammers, the manager, says that they are running on light charges at present and turning out 10 tons of bullion per day, and expect to increase to 15 tons. The value of the bullion varies from \$150 to \$300 per ton. They are closing up additional contracts for ore, and will have no difficulty in getting all that is necessary to keep the smelter in operation. These contracts are made with mines in the Coeur d'Alene, in Montana, and other districts tributary to Spokane.—The Bouton claim on Pine creek, in northern Idaho, has been bonded by Fred and Wiley Lasater, of Walla Walla, Wash. The claim is owned by Mrs. Tabitha Jones, of Walla Walla, and Theo. Jameson, of Wallace. The Bouton was located in 1887, and the assessment work has been done each year. The ore carries lead and zinc.

Spokane, July 10.

The Panhandle smelter at Sandpoint, which was blown in a month ago, is running full blast, its daily capacity being 150 tons, which will be doubled by the installation of another furnace. The company has contracts to keep it in operation for a year, and expects to pay off its indebtedness of \$38,000, within the next four months. In addition to the smelter, the company owns the townsite of Ponderay, the water-power, docks, steam tugs, and ore-barges, and also the Venezuela mine at the southeastern part of Lake Pend d'Oreille.—At the property of the Hayden Creek M. & M. Co., operating at Hayden lake, 42 miles east of Spokane, they are driving a tunnel from the creek, on the vein, and have obtained a depth of about 200 ft. and are 500 ft. in on the vein, which is 70 ft. between the walls. The ore is dry and will work with the cyanide process on the ground, being easy to mill. It carries gold and silver. There are 20 claims in that vicinity but little work has been done on any of them. The district starts near the lake and is close to Spokane. The country is easy for prospecting and it may develop into an important mining district.

SIOGSHONE COUNTY.

The regular monthly dividend of the Bunker Hill & Sullivan Mining Co. has been declared for July. This is the 122nd dividend, and amounts to \$180,000, making a total for the year of \$1,260,000, and a grand total of \$9,126,000 disbursed by the mine.—Thomas L. Greenough was re-elected

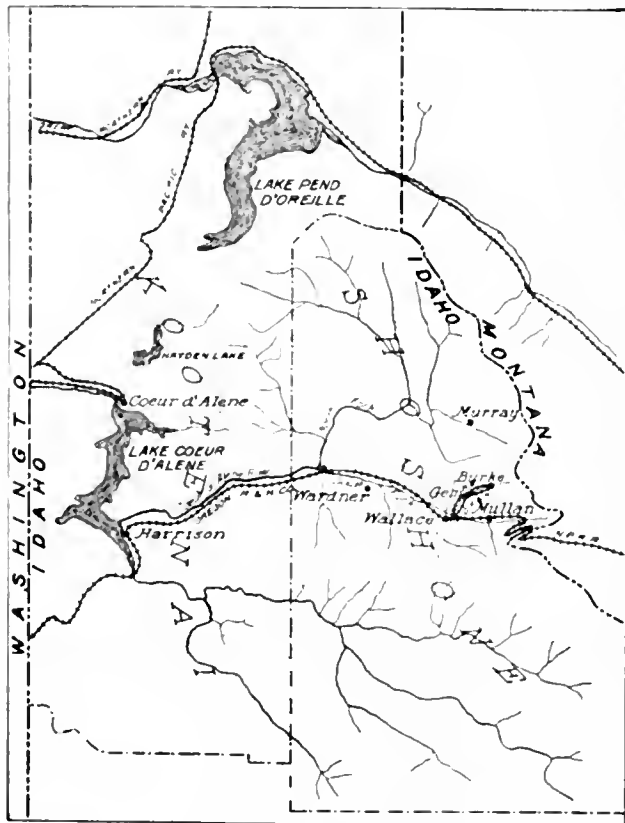

president of the Snowstorm Mining Co. at the annual meeting at Mullan, the other officers and directors being: Vice-president, W. D. Greenough; secretary, John Mocine; William Hunter, John H. Heward, Brush Greenough, and J. Broad, directors. The report of the manager of the company shows that the property is in better shape than ever before in its history. The company has just declared a regular monthly dividend of \$45,000, or \$260,000 to date. It has \$65,000 in the treasury and \$140,000 worth of ore in transit. It is the only copper producing mine in the Coeur d'Alene.—Another strike has been made at Murray, where the cross-cut from the 600-ft. level of the Paragon mine broke into concentrating galena ore. The cross-cut was run from the bottom of the 600-ft. vertical shaft. The company has spent more than \$100,000 on the development of its property. The drift from the shaft was nearly 900 ft. long. The property is equipped with a 15-drill compressor, and is employing 30 men.—The Federal M. & S. Co., of which Charles Sweeny of Spokane is president, has entered into a contract with Robert W. Hunt and Leroy Tucker of Kingston for cutting 370,000 ft. of stulls for use in the Federal mines. The price to be paid has not been announced, but a \$2,000 payment has been made to bind the contract. Stulls cost from 15 to 22 c. per foot, so the contract probably exceeds \$50,000. The stulls will be cut near the Kingston spur.—The Golden Chest mine, at Murray, is making a big showing, strikes having been frequent at various levels the last few weeks. A cross-cut was recently started from a point but 250 ft. from the mouth of the long tunnel on the Idaho level. This cross-cut, when in 30 ft., broke into ore that carries gold, tellurium, and copper sulphides, and will pay for shipping without milling.—Following the strike of ore at the Montana Standard property, at Mullan, a few days ago, the management is preparing to erect a 200-ton mill, and to increase its working force. A surveyor is at the property to establish a starting point for a raise to the second level. The vein of the Montana Standard has been explored 20 ft., and is in ore. A former discovery was made in the No. 3 tunnel 1,200 ft. from the surface, and 1,600 ft. in. The property is owned by Ohio people.—George W. Harris, of Wardner, has obtained an option on the Kingston antimony mine at the mouth of Pine creek, east of Spokane, and will get the property in readiness for shipping. The mine has not been worked for years, because of the low price of the ore, but it has been a producer.—James F. McCarthy, one of the managers of the property, announced that the Oom Paul will be a mine in 30 days. The ore showings are becoming better and if the improvement continues the vein will be cut within a month. They are now driving on the vein, and with 12 men at work are making good headway. The shaft is down 500 ft., and the ore showings have improved with depth. At first the vein was but eight feet long and two inches wide, but at a depth of 150 ft. the vein showed a length of 75 ft. with a maximum width of 18 in.—Reports from Wallace are that a strike has been made on Champion mine on Stevens peak, the main tunnel, now in 775 ft., breaking into chalcopyrite. The ore is similar to that of the Monitor and the Bullion. The strike was made on the foot-wall of the vein. The tunnel has followed the hanging wall for some distance, but accidentally swung toward the foot. How far the workings have been parallel to the orebody is not known. Cross-cuts from the old workings will be made, and meanwhile driving will be done on the showing, which is said to be six feet wide.—Ore strikes at and near Murray are frequent and the north side of the Coeur d'Alene promises to develop into as important a producing district as the south side now is. A strike was made on a new location at the head of Toboggan gulch, a mile and a half from the Waite property, a few days ago. The vein has since been exposed in three places by open-cuts, the deepest being 20 ft. One cut shows 15 ft. of ore, with the hanging wall still unexposed. The ore carries lead, and some of it is of shipping quality. The owners are H. R. Hall, W. B. Blackman, W. A. Taylor, and A. P. Blackman, of Murray.—Three feet of concentrating galena ore, carrying a small stringer of pure shipping galena, has been made at a depth of 500 ft. on the Consolidated mine, south of the Oro Fino

and Bear Top mines, near Murray. The holdings cover 4,500 ft. of a vein parallel with the Oro Fino. The mine, which has been under development a long time, is opened by a 100-ft. cross-cut, which, after the lode was found, was continued for nearly 1,300-ft. as a drift. In the face of the long drift the recent strike was made.—The Stanley mine, near Murray, has sent another car of gold and antimony ore to the White Metal company of Granite City, Ill. The ore assayed an average of \$25.20 gold per ton and 40% antimony. The White Metal company has agreed to pay 15c. per lb. for the ore. The property is on Gorge gulch. Two shipments, netting \$8,554, were made last year and regular shipments are now to begin from the mine, which is regarded as ready to join the regular dividend payers. The principal owners are Herman J. Rossi, M. J. Farrell, and a number of Spokane men. The mine is under the management of W. W. Merk.

MONTANA.

BEAVERHEAD COUNTY.

The Elkhorn Copper M. Co. has made a strike in the shaft on the Blue Eyed Annie, at a depth of 200 ft. Driving is

The Coeur d'Alene, Idaho.

In progress from the bottom of the shaft.—A five-foot vein has been struck in the Park mine, and arrangements will be made to sink 1,000 ft. more.

ELKHORN COUNTY.

Good reports come from the Butte & Beaverhead property, in the Elkhorn district. L. J. Price is running a cross-cut on the 150-ft. level, and shipments will start as soon as the road is completed to the mine.—A vein has been struck at a depth of 200 ft. in the shaft of the Park Copper Co. The company will soon start shipping. R. J. Philpotts is the superintendent.

RAVALLI COUNTY.

Spokane men are interested in the discoveries of copper in the Woodchuck district, near Florence, where the Bonanza Copper Co. has awarded a contract for a cross-cut tunnel in the Whaley mine. When this cuts the vein, which the management expects it will do early in July, the vein will be followed on the foot-wall until it is under the outcrop. A longer cross-cut tunnel will be driven later to cut the vein at a greater depth. The officers are: Joseph Felton, president; J. H. Tilsey, secretary; W. J. Doust, treasurer. They own 15 claims, and shipping ore has been uncovered.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence).—The production of Goldfield mines for the week ending July 13 was 3,919 tons of ore—an increase of 500 tons over the previous week. The ore was from the following: Mohawk, 1,226 tons; Mohawk-Combination, 1,000; Consolidated, 500; Little Florence, 267; Mohawk-Jumbo, 251; Red Top, 305; McNaughton, 125; Loftus & Davis, 108; Reltz, 55; Hayes-Monnette dump, 55; and Florence M. & L., 27 tons of ore.—A winze is being sunk from the 200-ft. level to the 260-ft. level in the Red Top. A new vein has been struck in this level, a station has been cut, and east and west drifts are being run from the shaft.—A mill for the concentration of ore without the use of water has been installed by the Little Florence Co. The first tests have been successful.—The Loftus & Davis lease on the Combination Fraction has expired, and the mine will be operated by the company. An unsuccessful effort was made to secure an extension on the lease.—Another strike has been made on the 200-ft. level in the Daisy M. & L. Co.'s shaft on the Daisy.—Work has commenced on the Frances group.—A shoot of ore running \$75 per ton has been struck at a depth of 140 ft. in the Combination Fraction. The find was made in the north-east drift from the vertical shaft on the Mohawk Combination lease.—A four-foot vein of ore has been struck on the 350-ft. level on the Mohawk.—A 30-ft. quartz vein has been struck at a depth of 340 ft. in the Red King.—The shaft at the Goldfield Big Four is down 132 ft. A hoist has been ordered by the company. An orebody running about \$5 per ton is exposed at the bottom of the shaft.—A station is being cut on the 160-ft. level in the Lou Dillon Montezuma near Diamondfield.—The Nevada Mining & Scientific Society has invited the American Institute of Mining Engineers to hold its fall meeting in Goldfield.

Goldfield, July 20.

LYON COUNTY.

(Special Correspondence).—The Ludwig mine has passed into the hands of the Nevada-Douglas Copper M. Co. The Ludwig has been a shipper of ore for several years. The ore is chalcopryite, in limestone.—The Bluestone is the most developed mine in the district, but it is not yet on the shipping list. The company has erected an experimental reduction plant, as the mine is a low-grade proposition.—Several churn and rotary drills are being used to prospect the holdings of the Nevada Empire Co. This property is owned by the Gelders, of New York.—A small smelter is on the ground, being used to test the ore.—Two working shafts and several prospect holes are being sunk on the Nevada-Douglas. A 2,600-ft. tunnel is being driven by three shifts on the copper vein recently exposed. Most of the ore thus far encountered is high-grade.—At the Western Nevada Indications are excellent, and exploration and development work is under way.—Salt Lake parties are developing the Malachite and McConnell claims, and some good ore is in sight.—At the Mason Valley, in which the Guggenheims are said to be interested, some excellent ore has been found.—The Yerington Central is showing up well, ore having recently been found.—Several claims have been located in the granite belt, which lies between the two limestone formations, but it is doubtful if they contain any ore. Extensive explorations have failed to disclose valuable minerals in profitable quantities in the granite ridge, yet several promoters have endeavored to dispose of stock in companies which have no property outside this unproductive granite belt.—The camp will be supplied with electricity from the Truckee river for power and lighting purposes. Southern Pacific surveyors are outlining a route for the new railroad. Yerington is situated on the east bank of the Walker river, in the midst of a farming region, and supplies are cheaper here than at any of the desert camps.

Yerington, July 18.

NYE COUNTY.

(Special Correspondence).—Tonopah mines produced 5,395 tons of ore during the past week, the yield being from the following: Tonopah, 3,580; Belmont, 1,285; Montana-Tono-

pah, 115; Jim Butler, 90; others 25 tons.—The 100-stamp mill being erected at Millers siding by the Tonopah Co. is nearing completion; 60 stamps are running and 10 more will be dropping in a few days.—The Montana mill is being rushed to completion.—The Tonopah M. Co. officials state that the failure of the mine to pay the extra dividend is due to the desire of the directors to retain sufficient capital in the treasury to guard against such dangers as the fuel famine, which hindered the operation of the property last winter.

Tonopah, July 19.

WHITE PINE COUNTY.

The power-line from the smelter to the Nevada Consolidated mines will be finished by fall, and the hoisting and underground haulage machinery at the Star Pointer will be ready by October. The concrete for the ore-bins and steel head-frame is being laid. Raises are being run in ore at the Ruth property.—A 15-h.p. gasoline hoist has been installed at the Robinson, and the shaft is down 100 ft.—Two churn-drills are operating near the Eureka shaft of the Nevada Consolidated property.—Some copper has been struck by the drills in the Weber and Clipper claims

Map of Eastern Nevada.

of the Ely Central. No. 5 hole has been put down 446 ft. in eight days. The Ely Central holdings are a crescent-shaped group, cutting across the porphyry belt and bordered on the north by the Nevada Consolidated ground. The property was acquired 18 months ago for Philadelphia capitalists, by F. S. and Joseph Phely.—A good deal of prospecting is being done in the Eagle district, 90 miles from Ely. Much work was done there 30 years ago.—The Muncey company, for which Marcus E. Jones is manager, will be reorganized in Salt Lake. Two carloads of ore were shipped last year, that averaged 24% and netted \$3,000. The company controls the waters of Kalamazoo and Muncey creeks.—A party of Salt Lake men, who are interested in the McDonald Ely and Success properties, have recently visited the mines at Ely. The Golden Gate and Mill shafts, and the old workings of the Robust company, were inspected. D. C. McDonald is manager for the company.—Good reports come from Osceola. The Ely Golden Ledge Co. has five claims there, and a placer claim at Hogum. R. M. Leshar is the superintendent.

WASHINGTON.

FERRY COUNTY.

Special Correspondence.—From the No. 1 cross-cut, 40 ft. below the surface at the Copper Key mine, a stope has

been excavated 60 ft. long in a direction slightly east of north. This stope is 45 ft. wide at the north and 23 ft. wide at the south end, and a drift has been driven on ore northward 30 ft. There is ore the full length of 90 ft. in the roof, sides, and floor of the stope and drift. The quantity of ore shipped to the Granby smelter, according to the statement of the manager, E. L. Tate, was 2,195 tons, the returns from which amounted to \$7.75 per ton in gold, silver, and iron, leaving a net profit over the wagon-haulage, railway transportation, mining, and treatment of approximately \$2 per ton. If a tramway is built from the mine to the Belcher Mtn. railway, an additional saving of \$2 per ton may be effected. From the floor of the stope a winze was sunk 60 ft., and a cross-cut from the bottom runs 55 ft. in magnetite, to the hanging wall, which strikes a little west of south and pitches southerly. The average value of the ore is about \$7 per ton. The No. 2 adit was driven 263 ft., and a raise from that point of 45 ft. connects with the bottom of the winze. At 153 ft. from the portal of the No. 2 adit a cross-cut was driven 85 ft., of which 43 ft. is through ore with pyrrhotite, marcasite, calcite, and a little silica. About 3 ft. from the foot-wall a stratum of quartz ore, 2 ft. wide, was cut, which has small streaks of chalcopryite through it and contains about 3% copper.—The Copper Key Mining Co. owns a group of nine claims in the Belcher district. A survey is being made of the surface and underground workings. There is a quantity of ore exposed, and the full extent of the deposits is not yet known, but there is more good shipping material exposed in this than any other mine on Belcher Mtn.—After the survey is completed work will be conducted on the No. 2 adit level, cross-cutting toward the hanging wall, afterward driving on it, to determine the course of the vein, and then sinking on it. Later, a new adit will be driven, to tap the vein at greater depth. The Copper Key Mining Co. is organized under the laws of Washington, with 1,500,000 shares, at a par value of \$1 per share, with 500,000 shares in the treasury. The directorate is composed of J. L. Prickett, president; D. G. Russell, vice-president; E. L. Tate, secretary, treasurer, and manager; T. E. McBroom, E. J. Dyer, and W. L. Jones, all of Spokane, Wash.—A fine body of silver-lead ore is reported to have been encountered in the Winnipeg mine.—The silver-lead vein on the Colville North Half group, north of Winnipeg, is improving with development. There is 15 tons of ore on the dump ready for shipment. A shaft is being sunk on the vein.

Republic, July 20.

J. C. Beidoliman, manager of the Amalgamated Republic Mines Co., which has taken options on seven properties near Republic, states that work on the construction of the mill at Republic will begin at once. He is closing a deal for the purchase of the old Republic mill, which has been abandoned. New machinery will be installed in the mill and work begun by the first of next year, and by a new process they expect to make it possible to handle the ore of the Republic mines at a good profit, at a cost of from \$2 to \$3 per ton. The mill will have a capacity of 280 tons daily. Experiments show that 90% of the gold and 95% of the silver may be saved.—The management of the Bortle Copper-Gold Mining Co. announces that a copper smelter will be erected this summer near Curlew lake, in northeastern Washington. The 500-acre tract will be platted and made into a townsite. There is a saw-mill on the ground and the construction of the smelter buildings will be begun within the month. The company's survey for a standard-gauge railroad from the lake to Belcher Mtn. is being pushed. The maximum grade so far is under 2%, and the curves are light. Construction work will begin soon.—The San Poil M. & E. Co. and the Seal Mining Co. have been incorporated in Washington to operate near Republic. The trustees are Charles E. Skiles, John W. Mickle, and M. Hannaford, of Philadelphia, Casper Howarth, of Chester, Pa., and A. L. Wright and S. L. Boyer, of Spokane. Philadelphia is to be the principal place of business. S. L. Boyer is general manager. The companies own nine groups of gold and copper claims.—G. Weaver Loper, president of the Colville M. & S. Co., operating near Republic, will install three 40-ton rotary furnaces on the property and have them in operation within 90 days. Other equip-

ment includes ore crushers and four electric compressor drills. They have improved 10 miles of the road from Republic to Park City and have built a road from Park City to Nespelem, 14 miles, and are now constructing a flume on Gold creek, seven-eighths of a mile long. Ore is being shipped to Nelson for demonstration purposes, pending the completion of the smelter. They are sacking three carloads of ore to ship to Nelson, which will average about \$1,000 per car.—Core-drilling will begin at once in the North Half group.—H. J. Hibscliam, of Davenport, and G. P. Garwood, of Keller, have closed a deal to buy and consolidate the Last Chance, New York, Reno, New York Fraction, Bonanza Fraction, and half of the Palmer Fraction lode mining claims near Keller.

BRITISH COLUMBIA.

The shipments of ore from the Rossland mines during the week ending July 13, were unusually large. The Centre Star broke all its previous records with over 5,000 tons. The following is the tonnage shipped from Rossland during the week: Centre Star, 5,010 tons; Le Roi, 2,240; Le Roi No. 2, 595, and White Bear, 210 tons of ore. Total for the week, 8,055 tons, making 146,147 tons for the year to date. The large compressor at the Centre Star is working. The work of development continues on the fourth and eighth levels of the Idaho. The ore that came from the old Centre Star workings and that has been on the dump for nine years, is being taken out by means of an inclined tramway, and shipped to the Trail smelter. In the Iron Mask stoping continues on the 400, 250, and 200-ft. levels.—At Le Roi, driving continues on the 200-ft. level of the Spitzee, and cross-cutting has begun to the south from the 1,650-ft. level toward the winze-workings. The ground west of the Josie dike is showing up well and furnishes a good deal of ore. At the Glant-California 25 men are working and a shaft will be sunk near the end of the California.

The Trail smelter received 5,781 tons of ore during the past week. In addition to the Rossland shipments, other sources of supply were as follows: Victoria, Nelson, 219 tons; St. Eugene, Moyie, 391; La Plata, Kokanee creek, 78; Arlington, Erie, 65; North Star, East Kootenay, 33; Rambler-Cariboo, Slocan, 33; Arlington, Slocan, 22; Lone Bachelor, Slocan, 21; and Sunset, 20 tons of ore. At Le Roi smelter at Northport, 2,240 tons were received from Le Roi mine. Three furnaces, treating 600 tons per day, are running, and the stock-pile contains only 20,000 tons of ore.

The smelter receipts for the week ending July 13 were as follows: Grand Forks, 18,742 tons; Greenwood, 14,730; Boundary Falls, 3,555; Trail, 5,781; Nelson, 273; Northport, 1,910; Marysville, 600. Total for the week, 45,591 tons of ore, and for the year, 757,455 tons. Many of the smaller properties are being developed in the Boundary region. Work has been resumed at the Bay mine, and shipments should soon start. The Diamond-Texas shaft is down 60 ft. in quartzite, and work will soon start on the Prince Henry.—The new electric compressor is working at the Sunset, and 30 men are employed. The International Coal & Coke Co. has closed a contract with the Canadian Pacific railroad for its entire output of coal, about 2,500 tons per day. The Fremont shaft is down 80 ft., and has been in ore part of the way. This mine adjoins the Strathmore.—It is expected that the Lenora copper mine and the Mt. Sieker railway will soon be opened and that ore will be mined this fall. This property was purchased this spring by the Vancouver Copper Co., a corporation of London, with a capitalization of 85,000 shares of \$5 each.—The Strathmore shaft is down 150 ft. and eight men are working there. About \$20,000 in high-grade ore has been shipped from the property.

In the Slocan district, a new concentrating mill is being built at the Blue Bell, at Ainsworth, for the recovery of lead and zinc.—The Reco is being worked again after being closed down for a year.

MEXICO.

CHIHUAHUA.

Parral produced 6,575 tons of ore during the week ending July 13, 2,725 tons being shipped to smelters and 3,850 tons being locally treated.—Bert Peterson and associates did

not purchase the Palmilla mine, and a 15-year lease on the property was given to J. F. Flynn and Eugene Davis of the Capazaya Mining Co. The mine has produced a great deal of rich ore, but has been badly worked, and the recent fire will necessitate a large initial expenditure, and the lower levels will have to be unwatered.—The Santa Rosalia smelter will be blown in again, and fuel, ore, and a working force are in readiness for the start. The plant has been idle for some time owing to dissension among the stockholders. The Lepanto mine is producing about 1,000 tons of ore per month, carrying lead, silver, and gold. This property is in the Naica district, and is owned by Antonio de Stefano, and is being operated under a 10-year lease by the Smelter No. 2 of Monterey. James A. Garrett is the superintendent.—The new 300-hp. electric plant at the Veta Colorado M. & S. Co.'s property at Villa Escobedo, has started, and work on the concentrator is progressing. A cross-cut is being run from the Buen Viento shaft under the San Rafael hill.

DURANGO.

It is reported by G. C. Palmer that Robert S. Towne and associates of New York are to finance the construction of a railroad between Zacatecas and Durango. The road will pass through Sombrerete, Nieves, La Noria, and San Matian.

JALISCO.

W. R. Ramsdell has taken a three-months' option on the Expectativa mines in the Ameca district, for \$200,000. These mines are 10 miles southwest of Ameca. Development work has been going on for two years and 10,000 tons of ore are developed, carrying copper, lead, silver, and gold. The ore will probably need concentration.—John M. Topper of Philadelphia has purchased the Purisima copper mine in the Ayutla district.—The Santo Domingo mines in the Hostotipaquillo district are shipping ore regularly to the smelter at Ezatlán. Air-drills will be installed in the Esperanza and San Pedro tunnels.—The copper smelter purchased by the Carrizo Copper Co. for its properties in the Aatlan district, will be erected at Ayutla and run on custom ore. A. L. Waters will be in charge. The Carrizo ore will be concentrated and the concentrate shipped to Ayutla.—The extension of the Guaymas-Guadalajara railroad is progressing.—The Bolaños Mining Co. of St. Louis is attempting to have set aside the court sale of the Bolaños mine to A. Beister. At one time these mines ranked fifth among the silver-producers of Mexico.—The Virginia & Mexico M. & S. Corporation has started work on the recently-acquired Cabrera, Peralta, and America mines, and 50 men are at work under Cesario Vargas. A tramway two miles long will be built and a new mill constructed.

SONORA.

At Cananea, more ore is being found in the Capote deep level at 1,050 ft. The presence of ore at this depth is considered a favorable indication for the future of this camp.—At the Cananea Ore Reduction Co.'s plant, the experiments on concentrating the fine tailing with tables are proving successful. The equipment is only experimental and the operations have been hampered by an irregular water supply, but this will soon be remedied. The plant is designed to treat the millions of tons of impounded tailing.—At the Sierra de Cobre, good ore is showing in the Limestone tunnel, but no ore had been cut in the lower tunnel. In the main shaft a pump-station is being cut on the 800-ft. level. From this point cross-cutting is being done.—English engineers, with Robert Mitchell, are examining the South Cananea property. The No. 1 and 2 shafts will be sunk and development will start on the south end of the property.—Michigan shareholders have been visiting the Ortega property. The Native shaft is down 65 ft., and will be continued to the 250-ft. point. An increased flow of water was encountered in the Huerfena shaft.—L. F. Gray, who is operating a silver-gold mine near Arizpe, is running a 10-stamp mill on the property, and will add a cyaniding equipment.—The first shipment of lumber from the Greene-Cananea mines has arrived from the mills of the Sierra Madre Land & Lumber Co., which will furnish the entire supply in the future, thereby saving the high haulage charges on Oregon pine. A direct railroad line may be built from the lumber camps to Cananea.

Special Correspondence.

London.

Deep Lead Mines. — Explanations and Prospects. — Zinc Corporation. — The Battle of the Processes. — Tin Discoveries in Australia. — The Ymir Mine. — Stratton's Independence. — Drovile Dredging. — Recovery of Mining Market.

At a recent meeting of stockholders in one of the companies which finance the group of 'deep lead' mines in Victoria, some necessary light was thrown on the circumstances that have brought about the adverse market position of these enterprises, the result of the delay in reaching the 'deep' ground, which six months ago the managers thought would be "a matter of a few weeks." The report states that toward the end of the year the public awoke to the fact that the Loddon Valley company had overcome the water, and upon that there was a considerable rise in the shares, as it was thought that the moment that the company got to the bottom of the shaft they were going to find vast quantities of gold which only needed to be shoveled out. That was not the view of the board; on the contrary, they knew very well that they had a great length of lead to deal with, and that they would have a large amount of development work, cutting across the river, and cross-cutting again from there, in order to find out where the payable runs of gold were. The former history of these 'deep lead' properties as worked by Australian owners, which had been such a marked success—having got out about £6,000,000 sterling—had been the same as in the Loddon Valley company. They had not had anything like the same difficulty with the water; but they had to discover where the runs of gold were in the old river-bed. C. Algernon Moreing, in referring to the samples of gold taken out from their trial washings, said he thought it would be interesting to see how uniformly they had found the gold in every part of the wash. In some cases the gold returns were of a very satisfactory nature. A sample of gold taken out from three fathoms of ground in a long cross-cut which had been put across the wash weighed 90 dwt., and was equal to 30 dwt., or 1½ oz., per fathom. Another sample from three fathoms in the same cross-cut gave 70 dwt., equal to 23 dwt. per fathom. The net result was that the 204 ft. which had been driven across the wash showed 17 dwt. 9 gr. per fathom. That was the result of 204 ft. across the wash of the Loddon at the present time. It was by no means a remarkable result; but they expected soon to get into a deep gutter, or channel, which would show a much higher yield. In their opinion, as engineers, the cost of working the wash would be about 8 dwt. per fathom, and everything over that would be profit. A Victorian Government geologist (Mr. Stanley Hunter) had given it as his opinion that it would require 10 dwt. to pay the working cost; but he (the speaker) thought 8 dwt. would be ample. He mentioned several cases of working companies which bore out his statement. At the present moment 'deep leads' were being worked in Victoria at a working cost not exceeding 8 dwt. What was being done at the Loddon was to drive through the wash to find the deep gutter where the rich gold was concentrated; but they had not yet reached that point, though they had found, as they approached the deep gutter, that the samples from the boreholes were richer. Although they did not regard these samples as giving any indication of the real value per fathom, what they found was that where the boreholes were richer the wash was always richer, and therefore they had every reasonable expectation that there

was much richer ground ahead of them than they were now working.

The Zinc Corporation has entered on a new phase in the vicissitudes of fortune that have marked its career since the establishment of the company some 18 months ago to deal with the enormous accumulations of tailing from the large Broken Hill mines. The Potter process for the recovery of zinc, lead, and silver was chosen as "having been definitely proved to be successful on a large commercial scale." Some 12 months later the results obtained were deemed to justify the increase of the company's capital from £350,000 to £500,000 for the expansion of the concentrating plant and the construction of a smelting works. The issue of 113,333 of the new £1 shares was guaranteed at the price of £1 5s. for the consideration of an option on the balance of the shares at £2 each. The market price of the stock rose to 55s., but a sharp fall on heavy Australian selling took place toward the end of February last. This was followed by the announcement that the Queneau system (the Potter process with the addition of magnetic separation) was not a commercial success, and that the Cattermole process,

Map of Part of Victoria, Australia.

which had absolutely solved the treatment of the tailing, was to be adopted. The shareholders are now informed that at extraordinary general meetings of the company, held in Melbourne, resolutions have been passed by which the head office of the company has been transferred to London, and that the London committee is now the board of the company. W. L. Baillieu and William Clark (who, by the way, were among the guarantors of the new capital) have resigned their seats as directors. Robert Skipwith, a partner in the firm of Chaplin, Milne, Grenfell & Co., and Henry William Pelham Clinton, a director of the Ivanhoe Gold Co., have been elected to fill the vacancies thus created. On the publication of this news the shares dropped to 5s., although they are a little better market at the moment of writing. It is thought that reconstruction of some sort for the purpose of raising more capital is inevitable. During the month of June 5,967 tons of tailing was treated; there was recovered 992 tons of concentrate, assaying 41% zinc, 7½% lead, 10 oz. silver. Assay of tailing, 16.26% zinc. Residue, 6.97% zinc.

It is reported that the West Australian Minister for Mines and the State Mining Engineer, who are touring the northwest mineral districts, have discovered what they

believe to be a mountain of tin near the town of Wodgina, which is hidden in the heart of the hills, one spur of which rises about 700 ft. above the plain and divides the field in two. Several mines of great promise are being worked on it, and there is a resemblance, in many respects, to Mount Bischoff, in Tasmania. Free tin is found in large quantities in granite lodes running in all directions through the schistose formation. The manner of working is simply to hand-pick the free tin and separate the finer tin by dry-sieving. In this way about 36 tons of ore, averaging about 68 or 70%, is raised and sent away monthly. Tantalite lodes to the north of the town were also inspected. A fine body of this ore was showing in the face of an open-cut on the hillside. Owing to the absence of a market, mining operations are at present suspended. A good many tons of free tantalite ore is at grass, and there is apparently as much more available as the market will be able to take for some years. A few tons have been sold at prices ranging up to £320.

Recent reports from the Ymir mine, in British Columbia, are considered satisfactory. Since the provision of extra capital by the issue of debentures, much progress has been made both in regard to equipment and development. The latest news is to the effect that crushing will start on July 15, and recent developments give promise that the ore which will be put through the mill will show satisfactory profits. This is the ore from the old vein, but the indications point to a discovery within a short period of an entirely new vein which may prove of great value. Stockholders look upon the present position as distinctly encouraging.

The new milling and mining scheme put forward by the directors of Stratton's Independence, on the recommendation of their consulting engineer, Philip Argall, was unanimously approved by the general meeting of the stockholders. Mr. Argall, who was present, made a well reasoned statement of the actual position of the mine and of the prospects of the Company after the inauguration of the new plan of working. He wound up his address, which was very cordially received by the meeting, by stating that the dumps alone would occupy the full capacity of the mill as suggested by him, for six years, and he thought a reasonable estimate would be that the aggregate tonnage to be derived from the dumps and from the low-grade ore in the mine will be ample to keep a mill of 10,000 tons per month capacity in successful and profitable operation for 8 or 10 years to come.

The London committee of Oroville Dredging announce that at the annual general meeting of the stockholders, held at Portland, Maine, on June 19, a resolution was unanimously passed "that dividends be continued upon the present basis of 24% per quarter until such time as a reserve fund of \$250,000 (£50,000) has been accumulated, and that thereafter all earnings over and above operating expenses be from time to time divided among the stockholders." It is estimated that after providing for the eighth quarterly dividend the balance of net earnings, together with the fund accumulated from the depreciation written off plant, machinery, etc., should produce a total approximating to the required surplus and the directors expect, therefore, to be in a position, after payment of the 9th and 10th quarterly dividends at the rate of 10% per annum, from the profits for the first half of the third financial year, to January 31, 1908, to distribute to the shareholders, in addition, a bonus of 2½%, and to continue such semi-annual bonus regularly, thus bringing up the total distribution per annum to 15%. It is further stated that any surplus profits which may accrue after payment of dividends and bonuses aggregating 15% per annum, will be dealt with in the directors' discretion,

either by increasing the semi-annual bonus, or by addition to the reserve fund.

The persistent downward tendency in the mining market appears to have received a check. The fortnightly settlement just concluded exhibits a fairly general, and in some cases a marked, recovery.

Butte, Montana.

Wages and Price of Copper.—The Corbin District.—Fire in the Minnie Healey Mine.—Discovery in the Maggie Claim.—The New Departure.—Sapphire Mining.—Water in Shafts.

The drop in the price of copper and the continuing dullness has created some uneasiness in Butte in apprehension of the possibility that the price of the metal may fall back to 18c. per pound, at which price the Butte miners have contracted to return to the old scale of wages, \$3.50 per day. When the miners made a demand for an increase to \$4 per day they entered into a contract with all the mining companies for a term of five years, agreeing to return to the old scale if the price of copper

Montana.

should drop again to 18c. When the contract was made the price ruled from 25 to 26c., and few persons thought it would go back to 18c. soon, if at all. Since the contracts were made the Western Federation of Miners voted to repudiate all such contracts between miners and employers, and made it unlawful to enter into similar contracts in the future. There is a general doubt whether the Butte miners would, in view of the Federation vote, accept a reduction in wages.

The ore in the lower adit of the Boston & Corbin Co. is increasing in width and value as progress is being made. A double-compartment shaft is being sunk from the adit, from which, at a depth of 200 ft., a cross-cut will be driven under the orebody. It is expected that within two months ore will be opened below the water-level. In excavating for a well recently, a fine vein of ore, about a foot wide, was cut on the Butte & Corbin ground. Other companies and individuals are pushing exploration work in the Corbin district. The Butte & Corbin Consolidated Copper Co., working on the east side of Valparaiso Mtn., has cut a vein carrying lead and copper. The Daly group of claims has been bonded to Eastern parties and preparations are under way to begin development work. There is a shaft on this property from which some ore has been shipped. The Jefferson-Montana Co. has installed new machinery and is running a cross-cut on

the 500-ft. level, the face of which is in 250 ft. There are two veins in the Jefferson-Montana ground, the larger one of which is about 500 ft. from the shaft. A shaft 240 ft. deep has been sunk on the Black Jack claim by Martin Mulvahill and partners. A station is being cut and the work has exposed the foot-wall of a vein, which will be explored when the station is completed. The main vein is believed to be about 65 ft. from the shaft.

Fire that broke out in the old workings of the Minnie Healey mine, between the 600 and 800-ft. levels, has proved more serious than anticipated. Mining had to be entirely suspended in the Minnie Healey, one of the Butte Coalition properties, and in the West Colusa, a Boston & Montana mine; moreover work could be done in only a small portion of the Leonard. The three mines are connected by workings, and the gas from the burning ore became so strong that the miners had to leave. When the fire-fighters thought they had the combustion confined to a small area in the Minnie Healey, it was discovered that it had made its way down to the 1,200-ft. level, but soon it was extinguished between the 800 and 1,200-ft. levels, and the fire was fought from all sides with steam and water. It was then only a question of time until it would be under control and the mines freed of gas.—The last of the three big air-compressors for use in the Leonard mine has been started up and works fine. The three compressors will operate about 150 drills, and occupy one large building. The eight new boilers at the Leonard are also in commission. They have a total of 2,000 horsepower.

A vein of sulphide copper ore two feet thick has been struck in the Maggie claim at a depth of 80 ft. The Maggie is a fraction lying between the Bullwhacker and Montgomery claims on the east side and is being developed by the owners. The vein has an east and west strike, it was found in a cross-cut 200 ft. from the shaft. In the Bertha, another fraction, situated a little northeast of the Maggie, some ore has been struck, but it is in the north and south fault-vein, on which the Bullwhacker is mining. Both the Bullwhacker and Bertha ore is silicious material having an average assay of about 4% copper. This vein has been a mystery to operators on the east side, as no one knows where it starts or where it ends. Until it was found in the Bullwhacker, no one knew of a north and south vein in the whole Butte district. Beyond the Bullwhacker, the Bertha, and Montgomery the fault-vein has not been developed, and its extent is therefore unknown. However, where mining has been done on it, it has yielded some very good ore.

The New Departure Mining Co. has practically completed the development work outlined at the time it purchased the property, and the company will devote itself to ore extraction, as there is a large quantity of it opened. A shaft 100 ft. deep has been sunk from the old adit-level and from the bottom the veins have been opened by cross-cuts. The New Departure is a silver mine, though the ore also runs well in gold and copper. The property is owned entirely by Butte men. Enough ore was taken out of the mine during development and exploration to pay for the work and leave a good balance in the treasury.—The companies mining for sapphire at Yogo are having a successful season, there being an abundance of water. Work has been resumed on the

Lehman group of claims, and the output of the London company will be the largest it has ever made.

Practically no water has been encountered in the various shafts that are being sunk north of the North Butte mines. The Butte-Milwaukee Co.'s shaft on the Colonel Sellers is down 460 ft., but there is hardly enough water in the shaft to provide moisture for the drills. The shaft on the Badger State is down 440 ft., and there is very little water to contend with. The Butte & Bacorn Co. is cutting a station at the 1,000-ft. point, and is not bothered with very much water.—The shaft being sunk on the Greenleaf by the Boston & Montana Co. has reached a depth of 900 ft. The company is also sinking the Mountain View and West Colusa shafts deeper. The former is to be made 2,200 ft. deep and the West Colusa 2,000 feet.

Mexico.

Railroad Building in Sinaloa.—Interference With Cost of Labor.—

Lluvia de Oro.—New Cyanide Plants in Chihuahua.—Improved Methods.

Until recently the railway system of the State of Sinaloa was represented by two short lines running from the coast to towns in the interior. The aggregate mileage

Sinaloa and Part of Sonora, Mexico.

could not be more than 85 miles. Today the Southern Pacific system is pushing the extension of the C. R. Y. y P. railway from Navajoa (in Sonora) well into Sinaloa. Within two months the section between San Blas (a few miles below El Fuerte) and Navajoa will be completed and in operation. Grading is now under way south of the Fuerte river, and every effort is being made to reach Mazatlan by the first of the year. The construction of this road is denuding the entire country of men and animals. The high wages being paid by the railroad has also had the effect of discontenting the vast majority of workmen in the State. While all welcome the railroad, the abrupt change of conditions is creating many difficult problems. Owing to the shortage of labor the cornfields are not being cultivated as actively as usual, and this, combined with the heavy demands of the contractors on the native supplies of corn, is having the effect of pushing the price of corn to an unprecedented height.

The Stillwell road, which has been working in a modest way for the last two years, has practically completed grading to the Choix river, and it is authoritatively stated that it will be in operation before the first of the year. This road will furnish means of ore transportation to the Pacific Coast smelters for a number of promising mining districts near Choix, as well as shortening the pack from the railway to the mountain mining camps.

It is stated that mining operations are to recommence

very shortly at the Lluvia de Oro. The mine has practically closed down for a year, pending the erection of a large treatment plant. The Mexico property is being actively developed by the Sierra Madre M. & D. Co. with satisfactory results. Recently two high-grade ore-shoots were discovered. The mineral is silver-copper, with some native silver ore. The discovery of this vein caused a local sensation about 18 months ago on account of the very rich ore, and because of the beautiful native silver specimens. Since the purchase of the prospect, about 10 months ago, by the Sierra Madre M. & D. Co., the amount of work done has been considerable, and the results justify the hope that the property will become one of the best mines in Sinaloa.

The mill of the Republica company at Sanz, in Chihuahua, has begun operations by dropping ten stamps. Two Wilfleys produce a concentrate worth up to P2,400 per ton. This plant will have a good cyanide plant, including air agitation, tube-mills, and some kind of vacuum-filter for slime treatment. Freight from the railroad is at the rate of P7 per carga. Water is abundant, and a power-plant will be built. The mill has a good saw-mill, and is close to fine pine timber-land. Good cool houses are being built for the American contingent. The mine is at an elevation of 5,000 ft., and enjoys a pleasant climate throughout the year.—The 20-stamp pan mill at Sahuayacancito is closed down for an indefinite period. Amalgamation proved unsuccessful on P25 ore. The plant could be remodeled easily and inexpensively into a fine-grinding cyanide plant, and would make money on such ore. Wood costs P9 per cord, but water-power is available nine months in the year. The condensing engine is a model of sectionalizing, and must have cost a fortune to lay down at the mill. A tailing pile of perhaps 15,000 tons—all that is left after summer rains—runs well in gold and silver.

The mill at Potrerito, owned by Juan A. Creel, of Chihuahua, is closed down, and is another example of a mill that could be made to pay handsome returns on a small additional investment in a cyanide plant. The western part of Chihuahua seems to be dotted with such plants. The Greene Co. had several such mills at Ocampo, all of which are now torn down. W. F. Thompson has started the Watterson mill as a cyanide plant, and, judging from results of experiments, will make much better extraction. He will cyanide the concentrate—a thing not successfully done heretofore on this class of ore. The Palmarejo-Mexican mill at Zapote was formerly a pan plant. It is now cyaniding, and upon the completion of the Butters filter, and the erection of a new classifying system, the mill will even better its present record. The slime-plant will consist of a 40-frame filter, which will allow of the re-treatment of old slime, besides handling the present output.

Salt Lake, Utah.

Utah Consolidated Plans.—Heinze Buys Smelter Site.—Harriman to Enter Bingham.—Zinc Ore Treatment.—Shipments from Park City.—News from Mercur.

The Utah Consolidated Mining Co. has not abandoned its plans to build a new smelter on the west side of the Oquirrh range of mountains. Reports to the contrary have been circulated recently, but J. B. Risque, the manager, states that the work will go on, though nothing is likely to be done in the way of construction this year. It is learned that the company's engineers have recently completed the survey for the proposed aerial tramway over the mountains, and have reported that it will be only slightly longer than the one operated at the present time, which is about 12,000 ft. It is also proposed to build

14 miles of standard gauge railroad to the smelter from a point near Garfield, where connection can be made with the main lines of the San Pedro, Los Angeles & Salt Lake and Western Pacific railroads. The company has recently completed the purchase of all the ground it needs for a smelter site and has secured the necessary water rights.

The agents of F. Augustus Heinze have recently purchased a large acreage of ground at Lake Point, about two miles west of the old Garfield Beach bathing resort on the south end of the Great Salt Lake; this will be the site of the smelter that Mr. Heinze and his associates intend to erect. The property has been obtained for the Miners' Smelting Co., organized not long ago under the laws of Maine. The site is a very advantageous one, since it will be accessible by all of the railroads entering the State. It is stated that Mr. Heinze is interested in a proposed interurban electric line from Salt Lake to Bingham, Garfield, and other local points and that behind it all is an understanding with E. H. Harriman, which will give the latter an entrance into Bingham. Under an agreement made several years ago, the Union Pacific and Oregon Short Line roads were to keep out of Bingham, leaving the field exclusively to the Rio Grande Western. In late years, Bingham has grown into such importance that the Harriman management has been anxious to get a share of the business derived from the operation of the mines and mills of that district, but this old agreement has prevented. By bringing Heinze into the suburban scheme the way would be open. On top of this comes the report that someone has secured an option on the Saltair Beach railroad, which could be extended to the Heinze smelter site with very little difficulty and it would immediately become a paying property.

A. J. Beetles, chief metallurgist for the Newhouse mining interests, has made the statement that he expects to have at least a portion of the Boston Consolidated mill at Garfield in operation by September. Splendid headway is now being made with construction.—The fourth unit of the Utah Copper Co.'s Garfield concentrating mill is in successful operation and the fifth is practically ready. Within a month the six sections will be running and treating ore on the basis of 3,000 tons per day.

An Eastern and local syndicate has in hand a project to erect a plant for the treatment of zinc ore at Park City. Officials of the Daly Judge Mining Co. are interested in the enterprise. It is expected that work will begin on the plant within the next sixty days.—Ore shipments from the Park City district last week amounted to 2,691 tons. Among the contributing mines and respective amounts were: Daly Judge, 592; Silver King, 838; Daly West, 492; Little Bell, 68; Jennings Con., 38; Copper Apex, 56 tons.

The Consolidated Mercur Gold Mines Co. is preparing to extract ore from the Brickyard mine, which was worked successfully several years ago. A recent sampling shows a large tonnage of low-grade ore. The slime plant being built by this company is about ready for trial, word having been received that the last of the equipment has been shipped.—The United Mercur Gold Mines Co. has been organized to develop a large tract in the camp of Mercur. As a basis for organization, the promoters have acquired the East Golden Gate mine and a controlling interest in the Ingot. Samuel Newhouse is mentioned as president of the company.—The Utah Copper Co. now has five steam-shovels at work on its Bingham property. Two are being used on ore and the balance in moving overburden. The latter has been cleared from an area about 600 ft. square. The surface deposit here had a thickness of 65 ft. The big bins in which to store ore from the underground workings, are now complete.

Leadville, Colorado.

Increased Importance of Placer Mining.—Work at Robinson.—Zinc Production.—News of Developments.—Successful Lessees.

It appears from the magnitude of the development work being carried on during the past few months by the Ximo Gold Mining Co. and neighboring companies that placer mining will again assume a position of importance in the Leadville district. The Ximo company secured 134 acres of patented placer ground near the junction of the south fork of the Arkansas river and Colorado gulch; a force of men is at work under the management of Timothy Kyle, with J. D. Page as superintendent. This company intends to install modern machinery at an early date.

At Twin Lakes extensive work is now being done with modern placer machinery and it is reported that a large acreage of placer ground has been secured by a Chicago company in the same vicinity.

Development work continues at the Reindeer shaft on Rock hill. It is expected that the shaft, which is now 840 ft. deep, will soon cut another contact; meanwhile the shipment of ores from the upper level continues. H. M. Shepherd, the manager, reports the deep shaft of the International Mining Co. of Robinson as being very near the contact that it was intended to cut. The property being developed by this company is locally known as the Robinson mine and has been an important producer for more than 20 years. When last worked the stopes were carried to the lowest point the water would permit, but the new shaft will enable the company to drain a large area heretofore untouched.

In spite of the fact that the Eastern zinc districts have increased their production materially, the local market does not show any ill effects. Purchasers are asking for increased shipments. It is expected that before the close of the year the supply will be considerably increased, since the larger bodies of zinc ore from the Louisville No. 2 shaft, the Tucson, Moyer, and certain newly developed zinc ore-shoots of the Yak company will become available.

Development work on various properties in Iowa gulch is proceeding satisfactorily and many new enterprises are under way. Major Bohn has made several important shipments through the Ready Cash tunnel from his Aurora property and at an early date he expects to increase his shipments to double the present amount. In the early days in this part of the district many shallow shafts were sunk, showing good ore, but water prevented deep mining.

The shaft at the Sunday mine on Ball Mtn. was completed to a depth of more than 450 ft. and connections are being made with the old shaft. Shipments will soon commence from the shoot opened up at the 450-ft. level. Eastern parties are reported to have made a deal whereby a large group of claims in upper California gulch will be developed, among which are the Eurydice, Joy Bird, and Grover Cleveland. Lessees on Fryer hill have made several discoveries lately, which shows that the rich pockets of that famous hill are not exhausted. Several lessees report pockets of silver ore and the Forepaugh is shipping about 20 tons daily.—The Rebote Mining Co., an enterprise that began operations on Rock hill during the early part of May, is making good headway with its new shaft. Alfred F. Wuensch, the manager, has installed an electric hoist which has proved to be very economical and satisfactory.—The shaft of the Foxy Grandpa Mining Co. in Iowa gulch is still being sunk at a rapid rate. A body of zinc ore was encountered more than a month ago, which later developments prove to be valuable in both zinc and silver.—It appears certain

that the Gold Bug property in English gulch will erect a stamp-mill. The tests made on a large lot of ore in Denver have convinced the manager of the advisability of doing so. Much activity is reported in connection with the placer operations of a new Chicago company on Lord's ranch. A dredge has been ordered and will be erected and in operation before the close of the year.

Denver, Colorado.

Cripple Creek Dividends.—Smelter at Lake City.

The annual meetings of the stockholders of the Elkton and Mary McKinney mining companies were held during the first week in July. Both companies report satisfactory progress, the gross production of the former being nearly \$700,000, and the net profit \$350,000; while the production of the latter was \$325,000, the dividends paid during the year amounting to \$196,000. Several others of the principle companies operating at Cripple Creek have issued equally encouraging reports, and the outlook for the district seems good in spite of the diminishing

Map of Southwestern Colorado.

production due to the trouble from water on the deep levels of the big mines.

The completion of the new large mill at Colorado City, the numerous small cyanide mills that are operating, or in course of construction, and the lowered freight and treatment rates on ores all combine to stimulate the output of low-grade ore, and the year will probably close with a much larger tonnage than ever before, but of a slightly lower value.

Leadville continues active. A recent improvement is the beginning of sorting operations at the A. Y. & Minnie mine. The grade of ore required for the proper operation of the mill had become scarce, and in order to keep up the production, the simple arrangement of sorting the ore up to grade was adopted. This at the same time allows the removing of mineral that it is desirable to keep out of the mill, and materially improves the separation. Placer work in the vicinity of Leadville continues to attract attention, and at Twin Lakes and in California gulch operations are being carried on vigorously.

The speedy construction of a smelter at Lake City is promised and the intention is to start it before winter, if possible. It is expected to operate by pyrite smelting. The owners of properties producing low-grade copper ore are correspondingly encouraged. In this connection one is reminded of a smelting company that has begun con-

struction work in another part of the State. The prospectus sent out is exceedingly bare of details, but, as nearly as can be learned from it, the essential feature of the process is to be the use of oil for a fuel, instead of the usual coke.

The trial of the process seems to have consisted in reducing some iron ore in a small cupola furnace in a satisfactory manner. This would have convinced most metallurgists of its unsuitability for the treatment of lead or copper ores, but appears to have had just the opposite effect on the experimenters. The total cost of treatment by the new process is given as 45 cents, a statement that defies serious comment. The disadvantages of the use of oil as a fuel in the shaft furnace for any other purpose than melting the noses off tuyeres, are so well known that it seems incredible that investors should seriously take up any process that did not involve some new and promising method of obviating them.

Johannesburg, Transvaal.

Collapse of the Strike.—Contract System Suspended.—Reduction in Cost of Mining.—Loyalty of Staffs.—Gold Output.—Details of Production.

The house of cards is falling rapidly. Of course the strike-leaders talk grandiloquently of their cause, and the certainty of their being successful in the present dispute, but as a matter of fact the battle is practically won. One would think that the misguided strikers would turn and rend the idiotic leaders who have landed them in such a fiasco, but the agitators continue to make their inflammatory speeches. Many of the strikers have gone back to work, and about the first thing they did was to resign from the miners' union.

The men who left their work voluntarily are coming back under quite different conditions. In the first place, the contract system has ceased for the time being. Instead of making £50 to £60 superintending two rock-drills, the miner is being paid £1 per shift to run as many rock-drills as the mine foremen think he can watch—an average of four or five. The hand-stoppers who were earning from 28s. 6d. to 32s. 6d. per shift for superintending 30 to 35 natives or Chinese are now being signed on at 16s. 8d. per shift, to run as many natives as required, from 50 to 60. No reduction has been made in the pay of timbermen, pumpmen, etc., who still receive £1 per shift. The contract system is only suspended for the time being, and will no doubt be introduced again later on, but the days when a Cornishman, or American, or a miner from any part of the world, could make £100 per month in the mines is forever past on the Rand. In the future about £45 to £50 per month will probably be the maximum that an expert miner will be able to earn.

For months past there has been an agitation here on the subject of working costs. It was generally agreed that the inefficiency and high wages of the white miners had to be changed, but the problem was how to do it. Ten years would have been required to accomplish what the miners have done for the industry in six weeks. The pay would have come down, but it would have been a very gradual process. The strikers have given the leaders of the industry a great opportunity to start afresh. The reduction of the white wages bill will do much to approach the working costs of 16 to 17s. per ton, which Ross E. Rowne in a masterly paper just read before a local society shows to be possible on the Rand.

At one of their mass meetings held at the beginning of the strike, the leaders told the men that the mills would be forced to close down soon after the strike was in full swing; monkeys would do the mining work quite as well as the raw white men that were being recruited

to work in the mines, declared the orators. Well, these monkeys are shaping remarkably well, and it must be a matter of the deepest humiliation to the band of strikers to see all the mills running, and to realize that their mad action has scarcely hung up any stamps. The staffs of the different mines deserve every credit for the loyal way they have stuck to their guns. Managers, samplers, surveyors, clerks, shift bosses, and mine captains have worked as miners during the past week, and have shown the greatest zeal in trying to keep the mills going. It must be remembered that the Kaffirs and Chinese now on the Rand are well trained, and do not require as much supervision as if they had just arrived on the mines. If for no other reason the strike of the miners was ill timed. Another fact which has helped us, is the refusal of the engine-drivers to join the underground men in striking.

The returns for the month of May show how little damage the strikers have done so far, as regards the out-

Map of the African Goldfields.

put. No doubt June will suffer much more. The total output for May was declared to be 524,477 oz., valued at £2,227,838. This shows a decrease of £53,272, or 12,542 oz., as compared with April. Of the total output for May, the Rand contributed 506,100 oz., while outside districts produced 18,377 oz. Although many of the mines show a decrease as regards the output of gold, still many of them will show record profits for May, on account of the reduced bill for white wages. This reduction will no doubt be a permanent one.

The Robinson mine takes first place for May, with an output of 23,449 oz.; next comes the Simmer & Jack with 20,649 oz.; then follows the Cason with 15,302 oz.; and fourth comes the Village Main Reef with 15,160 oz. On account of the desire to keep the mills going, the percentage sorted for the month shows a big decrease in some cases. True, the Princess Estate succeeded in keeping their 50 stamps at work, and sorting 10% at the same time, but on the large plants, which ordinarily sort from 18 to 20%, the amount of waste rock thrown out was only about 5 to 6%. On two mines there was no sorting at all. When conditions become normal there will be an increase in the sorting.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A CUPEL $1\frac{1}{2}$ in. diam., and weighing about 20 grams, is the size most commonly used in practice. The lead button to be cupelled in it should not weigh more than 20 grams.

ASSUMING that one pound of coke will yield 3,800 calories in the blast-furnace, since 3,325 calories of heat are required to flux one pound of silica, the coke required to do this work will be about 0.87 pound.

NORMAL SOLUTIONS contain in one litre the equivalent of one gram of hydrogen. Thus for acids or bases containing but a single replaceable hydrogen atom, the normal solution contains in one litre the molecular weight in grams.

SMELTER SLAG can be used to make a dam across a creek that is dry in summer, to hold water subsequently. This was done near Helena, Montana, a few years ago. Clay or cement should be used in the foundation to make the dam impervious.

AS DEFINED by the mineralogist, a crystal is the regular polyhedral form, bounded by smooth surfaces, which is assumed by a chemical compound, under the action of its intermolecular forces when passing, under suitable conditions, from the state of a liquid or gas to that of a solid.

IN INSTALLING a centrifugal pump to lift water from a river, care should be taken to place the pump as near the water as possible, with the suction pipe immersed in still water. Experiment has shown that if the in-take is in running water, the air in the riffle-water lessens the efficiency of the pump.

RESPECTING the relative merits of open and close-connected bucket-lines, it has been proved at most of the big dredging grounds in California that close-connected buckets may be used without serious trouble from operating causes, and that this arrangement is better adapted for the work than the open connection.

THE advantages of monolithic and reinforced concrete over all other forms of construction in foundations are seen in structures resting on yielding soils. The solid mass of concrete, as in a wall, tends to settle as a unit, and uniformly, even though the pressure may not be quite uniform on the entire foundation.

THE capacity of a bucket elevator depends upon the size of the buckets, the space between the buckets, and the speed of travel. The upper pulley generally drives the belt, receiving power from a side pulley, while the lower pulley should be hung in sliding boxes that can be moved by tension screws to tighten the belt.

Two drops of ammonia on a lump of sugar eaten immediately is considered a fair antidote for internal cyanide poisoning. This is usually the treatment when peroxide of hydrogen cannot be obtained promptly. In cases of external cyanide poisoning a warm bath containing bicarbonate of soda and common salt will allay the eruption.

THE British unit of heat, or the British thermal unit, is the quantity of heat required to raise the temperature of one pound of water 1° F. at or near the temperature

of maximum density, 39.1° F. The calorie is the French thermal unit, and is the quantity of heat required to raise the temperature of one pound of water 1° C. at or about 4° Centigrade.

THE load allowed on concrete piles should not exceed 20 tons per sq. ft. for those of large diameter. If there is any possibility of their acting as columns, as in the event of the surrounding earth being removed, the unit load should be less. Concrete is weak in columns, unless it is properly reinforced with steel. A better load on piles of small diameter is about 15 tons per square foot.

CAST-IRON pipes were formerly used for pumping under pressure underground, but are now rarely employed for this purpose. While cast iron is less subject to corrosion than either wrought iron or steel, the pipes are heavy and the sections difficult to handle. Wrought iron or steel pipe is almost universally used, an account of the less cost, greater security under water hammer, and greater facility in handling.

A CONCRETE with an angular coarse aggregate, such as broken stone, is stronger than one with a rounded aggregate, like gravel, although the rounded aggregate produces greater density, thus indicating a stronger adhesion of cement to broken stone than to gravel. However, if the sand is also angular, like screenings, the concrete with both rounded coarse and fine aggregate is the stronger, probably because of its greater density.

IN the Challenge feeder, which is really a variation of the Tullock feeder for stamp batteries, a circular cast-iron plate resting at an angle, is rotated beneath the hopper by a bevel gear, which, in turn, is moved by a friction arrangement varied by the blow received from the tappet on the stem, corresponding to the requirements of the stamp. At each partial rotation of the feed table a small quantity of ore is scraped off by the stationery wings resting on the plate.

CEMENT is being made from blast-furnace slag at several places in this country and abroad. Tests have demonstrated that it is of good quality, and for some purposes is equal to portland cement. It is manufactured by running the slag into water to granulate it, then drying below a dull red heat, pulverizing very fine, and mixing with 15 to 30% of dry, finely powdered, slaked lime. It is important that the slag should be thoroughly granulated in an excess of water, otherwise it possesses no hydraulic properties.

CAST STEEL is made by breaking blistered steel, or cutting bar iron into small pieces and melting it in combination with a small quantity of charcoal. When it is made from iron, manganese is mixed with it in close air-tight crucibles, from which it is poured into iron molds. The ingot is then reduced to a bar by hammering or rolling. Cast steel is the finest of steel and is known by a fine, even, close grain and a silvery and homogeneous fracture. It is brittle and acquires extreme hardness, but is difficult to weld without the use of flux. Other kinds of steel have a coarser grain and are less homogeneous, are softer, less brittle, and weld more easily. The best steel possesses the following characteristics: Heated to a redness and plunged into cold water it becomes hard enough to scratch glass and to resist the best files; the hardness is uniform throughout the piece. After being tempered it is not easily broken, welds readily, and does not crack or split. It bears a high heat and preserves capability of hardening after working; the grain is fine, even, and homogeneous.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

The Royal School of Mines.

The Editor:

Sir—Your London correspondent in his letter published in the issue of June 8, mentions certain happenings at the annual dinner of the Institution of Mining & Metallurgy, held on May 3, to which I desire to call attention. At this function the Rt. Hon. Reginald McKenna (President of the Board of Education) in responding to a toast, is reported to have said: "He was particularly happy in assuring the assembly that the new Imperial College of Science & Technology was on the verge of foundation." Among other bunkum and flattery with which this gentleman sought to feed the minds and elevate the souls of his auditors, he remarked: "The Royal School of Mines, which has created for itself a reputation extending the whole world over, would be affiliated with the new Imperial College." I infer from this official statement that the grand old Mining School has ended a long and honorable career at a time when its opportunities for extended usefulness were never greater and its good name and renown never more fully realized and appreciated abroad. It seems surprising to me that some old School of Mines man present, and there must have been a number, did not then and there enter his vigorous protest against this surprising and stupid indignity on the part of the Government. I sometimes think Englishmen lack sentiment, and when we hear of Lord Curzon begging, hat in hand, for funds to support the great University of Oxford, we may be pardoned the conclusion they are also deficient in pride. Is not the memory of Thomas Huxley, Dean of the Royal School of Mines, worthy of a better fate than this? We can imagine the discomfiture the Right Honorable gentleman would have received at Huxley's hands had he been present to hear this announcement. Why not consolidate the Royal Society, Geological Society, and Royal Academy into one organization, let Mr. Andrew Carnegie endow it, and call it the Imperial Carnegie Institute; that would have then made a complete job of the consolidation.

England's Empire does not need an Imperial brand, she is great and good because great men made her so, and similarly the Royal School of Mines is famous because famous men labored to build it up and to train some of the best mining engineers the world has ever had. Are not these traditions worth cherishing or are they to be forever blotted out by this Imperial humbug? I venture to think we Americans would never be guilty of such stupidity; we cannot make our great teachers dukes, lords, or Right Honorables, but we can and do hand down their names and memories to posterity in a fitting manner connected with the institutions they were instrumental in making great and worthy. Witness the endowment of chairs, scholarships, and funds in all our large universities. Had we the fortune to have possessed Huxley, Murchison, Smyth, Percy, Judd, and other great teachers less known to fame, I venture to assert an institution that such men had labored to create would never be extinguished by a parcel of politicians. Our political sins and lapses are not a few, but the canker of political scheming has seldom or never been permitted to affect our institutions of learning. Think what would happen should Congress propose to extinguish the the Smithsonian Institution by affiliation with, we will say, the Geological Survey (no reflection upon that excellent or-

ganization is intended). And it might be pertinent to ask in this connection why did Smithson, an Englishman of scientific attainments, come to America for an opportunity to found such an institution? Perhaps a similar reason now prompts an American to protest against the virtual extermination of the famous old English technical school in which he was once a student.

F. LYNWOOD GARRISON.

Los Angeles, July 10.

Cyanidation in the Transvaal.

The Editor:

Sir—We have read in your issue of June 8 some statements made by your Johannesburg correspondent in connection with our metallurgical innovations on the Rand which have considerably astonished us, and we trust that as you have circulated through your journal statements which are calculated to do us some harm you will grant us the use of your columns to rehabilitate ourselves in the eyes of your readers.

Your correspondent begins by stating that "several of the mines under our control spent thousands of pounds to install the process of circulating cyanide solutions advocated by the Denny brothers," and follows this with a quotation from the address of the Chairman of the New Goch Co. (on which mine we installed one of our plants), and an observation of his own that the Chairman's statement referred to "is rather disconcerting to the 'new metallurgy.'"

Before proceeding to deal with the Chairman's remarks on the subject of our process, we would like to point out that not a single pound was spent by us in the installation of the process for circulating cyanide solutions. We purposely built our plants so that in the event of our wishing to try the effect of circulating solutions they were as readily adapted for that as for our ordinary treatment without circulating cyanide solution, which we had installed at the Van Ryn mine, and which, we may add, is the system to which it is proposed now to revert at the New Goch. It would have been fair to us, more especially as we are not on the Witwatersrand, to reply to your correspondent's criticism, if he had stated that after all, the only portion of the plant that the Chairman of the New Goch found fault with was the system of circulating cyanide solution, and that the main principles of our plant, embodying tube-milling, automatic slime-treatment, and filter-pressing, remained as highly successful elements of the 'new metallurgy,' and constituting, of course, as the technical man knows, practically the whole of the 'new metallurgy.'

Coming now to the distinct feature of our system, which has been pronounced by the Chairman of the New Goch to have given rise to difficulties, we would observe that the test of the efficiency of a plant is high extraction coupled with low working cost. Neither of these claims are questioned by the Chairman, who clearly states that it is the intention to abandon the circulating cyanide solution method, merely because of the unreliable nature of the screen-assays, which had given rise to erroneous estimates of the gold to be expected at the monthly clean-up.

Adverting first to the efficiency of the plant, we may say, without any fear of contradiction, that the residue from the plant will not average more than from 1 to 6 grains, when in the former plant the average was from 18 to 21 gr. This result cannot be said to be unsatisfactory.

The assertion of the Chairman that the screen-assays have proved unreliable is one we can neither contradict nor confirm. In our complete paper, read before the

South African Association of Engineers, in June, 1906, we admitted the difficulties inherent in the practice of screen-sampling, when the sample itself is subjected to the solvent effects of weak cyanide solution; but we also pointed out very emphatically that the ordinary system of screen-sampling, and especially the usual method employed on the Rand, were open to even graver charges of contamination, which charges were not rebutted in the ensuing discussion.

As a matter of fact, we might mention that the screen-assay at the New Goch during several years of our experience, was as unreliable as it could possibly be, and we attributed it then, and now, to the fact that the ore of the mine contains unusually coarse particles of free gold, and therefore we do not believe that the abandonment of the circulating solution will overcome the difficulty, while we are certain that the working costs will be higher and the extractions lower. We make the last statement quite advisedly, because we ran the plant at the Meyer & Charlton mine (a plant the exact counterpart of the New Goch plant), first without cyanide solution, and carefully noted the results; and subsequently with cyanide solution in circulation, thus getting actual working figures for comparison. The important differences are given in our paper previously referred to.

What is the more inexplicable part of this change-over on the New Goch mine, is that with an exactly similar plant at the Meyer & Charlton, extraordinary success has been attained; which is attested by the fact that the manager of the mine, when showing the members of a scientific society over the plant at the end of last year, stated that the extraction up to that date, nearly a year after the plant had started running, was 95%. We may mention that with the former plant, our extractions averaged between 80 and 85% only, so that the new plant, according to the official statement of the manager, is responsible for 10% higher extraction, at an increased working cost of one shilling per ton; the net result being from 4 to 5s. per ton profit in favor of the new plant. Our estimate on which the plant was built was a net improvement of 4s. per ton in the profits.

It is interesting to observe that the chairman of the New Goch, who is also chairman of the Meyer & Charlton, stated in his annual address in 1907, when dealing with the operations for the past year, that "the larger profits resulting (from the year's work) have more than justified the expenditure occurred in the additions to, and improvement of, the plant." He further stated that "the company had produced more gold and earned a larger profit than in any previous year," the actual figures being with the old plant for 1905 a gross profit of £99,784, and with the new for the year 1906 a gross profit of £136,967, or an increase of over 36 per cent.

The question now arises why, with the Meyer & Charlton plant, such magnificent results have been secured, and why at the New Goch they have been so disappointing as to give rise to the criticisms and damning statements of your correspondent.

We are in position to say that during the time we were in control of the plants, we made complete clean-ups of the new Meyer & Charlton plant, first, to satisfy ourselves that the gold called for, as between the screen-assays, and the residue-assays, was in the plant, and subsequently, at the instance of the Chairman of the company, on more than one occasion, to satisfy his doubt on the matter. The clean-up was in each case a complete vindication of our methods, as we had in each case a plus extraction. In the face of these results, and of the actual record of the Meyer & Charlton with its new plant, for 1906, we think that you must agree that your correspond-

ent's strictures, and his concluding observation that "it is fortunate for the rest of the Rand that conservative counsels prevailed, and that the mines of other groups did not take up the metalliferous schemes so persistently promulgated by the Messrs. Denny," are unfair. It is rather unfortunate for your correspondent that this final statement should, in any case, so inaccurately represent the actual situation.

We were solely responsible for the introduction of tube-mills, and the leading, if not the only, advocates, for fine-grinding, and secondary amalgamation. Our principles have been accepted and a plant to carry them out has been installed on every up-to-date mine on the fields. We are again solely responsible for the introduction of filter-presses to the Rand. Slowly, but surely, these appliances are being installed, and no less than five big mines are at the moment putting them in. We are solely responsible for the introduction to the Rand of a new form of mortar-box, in which the water-feed is delivered through the back of the box, at about the level of the die. We learn from the consulting metallurgist to the leading group on the field, that the same method has been adopted by them with the greatest success.

In conclusion, we would say that when the whole cause of dissatisfaction with our plant is boiled down it merely refers to the fact that on a particular mine, disappointments in the gold yield have been experienced, which on that particular mine, is no new thing. We assert without any fear of contradiction, that the only other mine on which we installed a plant, where the disappointments indicated have never existed, a complete clean-up of the plant has always shown rather more gold than the screen-assay called for. The reversion to the so-called decantation system about which the Chairman of the New Goch and your correspondent have both made so much, does not invalidate one single principle of our scheme, nor cause the slightest alteration to our plants, other than the substitution of water for weak cyanide solution, and a dam for receiving the slime and solution from our specially designed slime-plants, which latter, as a matter of fact, we provided before the plant was started.

The whole of the details of this scheme we worked out, and successfully practised at the Van Ryn mine, with an equipment of 160 stamps. We are sorry that an explanation of the true position in connection with our plant has necessitated so much space, but we believe it to be due to our friends and ourselves to state the position fully and clearly.

DENNY BROS.,
Per G. A. DENNY.

London, June 27.

CANADIAN EXPORT TAX ON IRON ORE.—Premier McBride has made the important announcement that at the next session of the British Columbia legislature, to be held in February, 1908, the Government will pass legislation restricting the export of iron ore from British Columbia to the United States or other foreign countries. He stated that capitalists resident in the United States had acquired large holdings of iron ore in the province with the avowed intention of shipping the same to the United States to be used in smelting works there. A large export tax will be placed on ore shipped outside of Canada, which would be remitted when ore was smelted in the province. He referred to the vast beds of iron in Vancouver island which have been acquired by American capitalists for use in smelters in process of erection near Port Townsend. It is intimated that the effect of this warning may result in the erection of smelting works on Vancouver island, especially if the Dominion Government grants a bounty therefor.

Working Costs on the Rand and Comparisons With Mines in California.

By ROSS E. BROWNE.

*During a sojourn of 20 months on the Rand, from January, 1904, to September, 1905, I had occasion to collect information on the subject of working costs. My employers, while not responsible for my views, have authorized the publication of my text on the above subject, hoping that discussion may bring out the *true* situation and clear the field to some extent for systematic consideration of measures designed to reduce the prevailing high costs.

The term 'working cost' will be adopted as referring to the running expense of the fully equipped mine. It includes the cost of developing, extracting, and treating the ore, and all attendant expenses of management, but

The subsidiary companies of the corporation known as Rand Mines, Ltd., have based their accounts in the main upon the above conception; yet the large cost of development prior to the date of milling was charged to capital account and is not redeemed out of the yield. It would have been more in accord with the principle stated to maintain for this purpose a suspense account for gradual distribution, but the complication was unnecessary and was therefore avoided. These companies charge to working cost the actual expense of development during the current year, irrespective of any close correspondence between the number of tons developed and the number mined. In the yearly total for the nine mines the discrepancy is small. The running capital account is small and apparently well controlled.

Many other companies on the Rand adopt a fixed development redemption charge per ton of ore milled—a charge

On the Rand. Simmer & Jack. No. 2 Shaft.

excludes the cost of shaft-sinking down to the lode and all original equipment.

Assume a simple case. The mine has been opened by means of vertical shafts down to the lode. Full surface and shaft equipment have been provided for operation on the basis of a fixed stamping capacity. The ore is to be mined and treated as fast as developed. Then the total cost to date is 'capital expenditure,' and the expense henceforth is 'working cost.'

But few mines are fully equipped in the beginning, and development commonly precedes the operation of stoping. We must then maintain a running capital account and a suspense account. Definitions vary, and we seldom find a consistent line drawn between 'capital expense' and 'working cost.' The distribution of expenses is left to the discretion of managers and secretarial staffs. It is commonly understood that there should be charged to working costs all current expenses excepting those that are incurred in providing for an increased capacity of the works. The expenses of repairs, renewals, and replacements are included.

which seldom corresponds closely to the actual cost. There is a wide variation in the percentage of waste sorted out of the rock mined and delivered to the surface—varying from 5 to 35%. As the working costs are calculated per ton milled the figures thus furnished are not directly comparable. The records of tons mined and tons milled are often unreliable within 5 or 10%; and the tonnage developed is, within certain limits, a matter of estimate.

It is apparent that the working costs per ton of ore, as usually published, are not based upon common measures, and for comprehensive comparison there is required a uniform system of distributing the expenses and close scrutiny of the details. It is customary on the Rand to record many statistics, and with these in hand we may generally get at some reasonable basis for comparison by taking the necessary pains.

Roughly, the average yield of the Witwatersrand at the present time (September, 1905) is 35.7s. per ton of ore milled. The working cost is 24s*. The capital expenditure, if systematically redeemed out of the yield, would mean a charge of about 5s. per ton. The tax in-

*Abstract of paper read before the South African Association of Engineers, on June 1, 1907.

* A shilling is equal roughly to 24 cents.

posed by the Government is 10% of the profit. We thus have for the average case:

Working cost.....	21.0	shillings	per ton milled
Capital redemption.....	5.0	"	"
Total expense.....	29.0	"	"
Yield.....	35.7	"	"
Profit.....	6.7	"	"
Profit tax.....	0.7	"	"
Company's profit.....	6.0	"	"

This is a crude estimate; a close calculation would involve an examination of all accounts in detail, which has not been attempted.

The nine producing companies of the Rand Mines, under the general management of George E. Webber, keep comprehensive accounts, affording good facilities for analysis. These are the Glen Deep, Rose Deep, Geldenhuis Deep, Jumpers Deep, Nourse Deep, Ferreira Deep, Crown Deep, Langlaagte Deep, and Durban Roodepoort Deep—all representing 'deep level' mines of moderate depth—average about 1,200 ft. vertical. They are scattered along the length of the main producing area, and in the aggregate fairly represent the conditions of the Witwatersrand. The equipment is more modern than the average, and the working costs are somewhat lower, though not the lowest. It is proposed to use these accounts to represent the modern practice.

There are a number of causes of variation in cost. The most important of these is the number of stamps operating. However, in cases of exceptional deviation from the normal type other causes may become equally or even more important. Thus the Nourse Deep costs are excessive owing mainly to the abnormally faulted condition of the ground. The Rose Deep costs are low owing to the great width of stoping. The stopes of the Rose Deep have recently narrowed down and the cost per ton has risen. The other mines of the group show persistent decrease of cost per ton, with increase of the number of stamps operating. By doubling the number of stamps the working costs per ton of ore is reduced by 10 or 15 per cent.

The following figures refer to the normal type of mine, and while extending beyond the limit of experience, they are still deemed to represent fairly the present conditions:

Number of stamps operating.....	100	200	300	400
Working cost per ton milled (shillings).....	21.8	19.0	17.7	16.8

By way of summary it may be stated that with 1,200 ft. depth of mining, 5.75 ft. width of stoping, 13% sorting, and 110 stamps running, the working costs per ton of ore milled are:

In mining, including development.....	14.00	shillings.
In milling.....	2.82	"
In cyaniding.....	2.64	"
In management and general expense.....	1.81	"
Total.....	21.27	"

These figures appear high in comparison with the costs of economically worked gold mines elsewhere. What are the controlling causes?

There are available the accounts of various gold mines in America. These show wide variations in width of stoping, hardness of the rock, and treatment of the ores, and fair criteria for estimating the relative efficiency of work are difficult to obtain. The data are incomplete, in fact, the bulk of the information serves only to illustrate the futility of attempting comparisons without various elements of parallelism in the conditions and personal examination of details.

Two California mines were specially selected for comparison on account of similarities in depth of mining and width of stoping, the comprehensive character of the accounts, and my own familiarity with local conditions. These are the Oneida mine on the Mother Lode, and the

Empire mine at Grass Valley. These are among the better managed mines of the West. In connection with the Oneida, the necessity for economy is apparent from the low yield.

COMPARATIVE TABLE.

	Rand.	Oneida.	Empire.
Average vertical depth of mining (ft.).....	1,200	1,600	1,000
Number of stamps erected.....	131	60	40
Cost of plant (equipment) (£).....	425,000	50,540	45,400
Per stamp (£).....	3,244	840	1,132

Average dip of lode or vein.....	30°	65°	28°
Yield per ton milled (shillings).....	36.5	14.0	—
Mine water pumped (Imperial gal.).....			
Per 24 hours.....	163,149	58,408	750,000
Per ton milled.....	303	226	7,500
Percentage of ore cyanided.....	100	—	—
Percentage of concentrate produced.....	—	1.4	—
Percentage of sulphides in ore.....	2.5	1.5	2.4

In obtaining a basis for comparison of costs there are to be considered primarily the *natural* advantages and disadvantages as distinguished from those *artificially* established by man. The representative Rand mine has thus the advantages of two payable lodes in close proximity, each of fair stoping width, and furnishing a relatively large amount of ore over wide areas, also a remarkable stability in the walls of its openings. Its disadvantages are in the hardness of the rock, the flat dip of the lode necessitating expensive handling in the stopes, the necessarily high cost of water and treatment.

The Oneida has the advantages of softer ground for mining, steeper dip of vein, cheap water-supply, and simpler treatment of the ore. Its disadvantages are limited supply of pay-ore in one vein only, and instability of the walls of its drifts and stopes, necessitating expensive timbering.

The Empire has the advantages of cheap water-supply, both for battery use and power, and simple treatment of the ore. Its disadvantages are hard rock, limited supply of ore, narrow stoping width, flat dip of vein, instability of the hanging wall, and a large amount of underground water.

The working costs, in shillings per ton of ore milled, are as follows:

Rand Mine: 21.27. Oneida: 10.93. Empire: 18.73.

But these are not upon a common basis, since the Rand mine sorts out a portion of the waste from the rock mined and hoisted before milling, and the proportion of rock developed was not the same. Taking these matters into account the costs are:

Rand: 19.63. Oneida: 10.67. Empire: 18.03.

The effect of differences in natural conditions is at once apparent in comparing the Oneida with the Empire, where the costs are widely divergent, while the labor methods and efficiency of management are practically the same.

The ratios of the numbers of tons mined per month are about 5:2.5:1. If the California mines furnished ore enough to justify the stamping capacity of the Rand mine, the costs would probably be:

Rand: 19.63. Oneida less than 10. Empire less than 15.

The stoping widths are:

Rand: 69 inches. Oneida: 71. Empire: 48.

If the Empire width were increased to 69 there would result a further reduction in its costs.

The most significant consideration concerns the number of men employed per ton of ore. The numbers per comparison ton are about as follows:

Rand: 1.95. Oneida: 0.54. Empire: 1.

With similar stamping capacities the numbers would probably be as 1.95:0.5:0.8.

The Rand figures are based on accounts prior to importation of Chinese labor. Since then the numbers have greatly increased, and it is probable that a comparison with the California mines at the present time would show that the Rand mine is employing fully four times the number of men per ton of ore.

But all these figures require radical modification before any measure of efficiency can be inferred from them, as the appendices to my report will indicate.

Comparing the Rand with the Mother Lode, a much higher cost is legitimately due to the greater hardness of the rock and the necessary treatment of the ore. This is partly, but not fully, balanced by the stability of the walls of the openings and the exceptional continuity of pay.

Comparing the Rand with Grass Valley, the *natural* conditions, so far as they concern working costs, are on the whole favorable to the Rand.

In order to obtain some measure of the efficiency of the work a series of estimates have been attempted on the basis of the data in hand. The results reduced to the basis of 100 stamps are given in the following table:

1. Present working cost per ton milled.....	22 shillings
2. Substituting California labor, wages, cost of supplies, economy of management, etc.....	17 "
3. Under the most favorable conditions, with efficient skilled white labor and white direction of colored labor, reduced cost of supplies, etc.....	15 "
4. With efficient labor, exclusively white, present white wages, present cost of supplies, etc.....	26 "
5. With present white labor, and substitution of available white for the present colored labor—maintaining present average white wage, cost of supplies, etc.—a reliable estimate, cannot be made, but the figure would probably exceed.....	35 "

REDUCTION OF COSTS.

The significance of a speedy reduction of the average working costs of the Rand, from 24s. to say 16s per ton, is apparent from several different standpoints. To the shareholders of the operating mines it means doubling the dividends. To the owners of undeveloped properties it means a great increase of present value. To the community at large it means a great increase in the output and a rapid rise in prosperity. There is a vast area that can only be rendered payable by the reduction of costs. The present operating mines would add materially to their stamping capacities, and many new enterprises would be inaugurated. A large portion of the gross production, probably exceeding two-thirds, passes through the hands of the local community.

The fact must be recognized that whereas the Witwatersrand contains, in a comparatively small territory, a greater quantity of gold than was ever known to exist elsewhere in an equal area, the average grade of the ore is low. In the first working the higher grade ores were particularly sought, and the yield per ton is naturally and inevitably diminishing. Unless something is done to reduce the high cost, the greater part of the value will be lost to the present generation, and much of the ground will be botched for further working.

One occasionally hears the statement made that the low-grade ores will "keep," and may be worked later on when the absolute necessity for lower costs is forced upon us or our successors. Without conceding the desirability of leaving the better development of the industry to our successors, we may admit the truth of this statement in so far as it concerns undeveloped territory, but it is fallacious if applied to the present working mines.

In the average operating mine of the Rand the masses of ore yielding less than 22s. or 23s. must now be left behind. In the course of time the mine will be dismantled and left to eave—many of the older workings are already eaving. The re-opening and rehabilitation of the mine will be costly, and it will be worked at a disadvantage, if at all. It is safe to say that reducing the cost to 16s. today would mean, aside from the incomparably greater profit, a greater ultimate production than reducing to the same figure 10 years hence.

But no one acquainted with the facts will seriously deny that the immediate interests of the industry demand a radical reduction of the costs. The question is: How shall the reduction be brought about?

As long as we confine ourselves to the methods of prospecting, testing, and developing the lodes, and to the character of the machinery, buildings, and appliances, we may say that the engineering work has been excellent. Where the engineer has failed in his attempt to produce good results has been in the handling of the labor. That much of the present labor, especially underground, is deplorably inefficient is generally conceded. It is understood that efforts have been made from time to time to establish a reasonable standard of a day's work, but that the many economic and political obstacles in the way have been discouraging and often insurmountable. The Transvaal has been in a state of political turmoil, rendering impracticable many of the proposed measures of economy.

Among the many considerations involved in a reduction of costs, the one of primary importance is a positive improvement in the efficiency of the labor. Many suggestions have been made. It has been proposed to introduce the conditions of America and Australia, and to operate the mines exclusively with whites. But it would be impossible to provide efficient white labor in the large numbers required, in reasonable time, and unless the conditions were so radically changed as to permit of a much lower wage than now prevails, the cost, however efficient the labor, would be higher than at present. It has also been proposed to displace part of the colored labor with unskilled white labor, providing a wage intermediate between that of the Kaffir and that of the skilled white. The changes involved are generally regarded as wholly impracticable. South Africa, with its preponderating numbers of blacks, is not the country for cheap white labor. The black man is there to stay, and must be dealt with. He must be controlled, and efficiency of control demands utilization of his work. The assignment of similar work to whites and blacks would result in lowering the standard for each, and breaking down the barriers that are essential to the supremacy of the white race. A distinct line of separation in the duties of skilled white and unskilled colored labor is of paramount importance. Fortunately for the mining industry this division of labor, with efficiency on both sides of the line, will lead to the best possible results. This is doubtless generally conceded by those most familiar with the work.

It is furthermore only in this way that a high average wage of unskilled labor can be maintained, and a desirable status for the white man can be upheld.

The value of the Kaffir labor under reasonably efficient direction is well recognized, and the economy is somewhat strikingly exhibited in the low cost of coal mining on the Rand. Coal mining is incomparably simpler than gold mining (including treatment of ore) and calls for a much smaller proportion of skilled labor. The illustration is nevertheless significant. In the presence of the low cost of coal mining, the high cost of gold mining is clearly attributable to the inefficiency of the skilled labor,

either directly or in its supervision of colored labor. From the various considerations involved it is quite manifest that under existing conditions, or any conditions that may reasonably be expected, the colored labor is of vital importance to the working of the Rand mines.

It is believed that machine-drilling under proper supervision is the proper thing for the Rand. Generally

lower. Under the most favorable conditions it is plainly possible to lower the cost to 14s. without materially reducing the high average white wage now prevailing. A high wage is desirable for many reasons, but is not feasible without return of efficient service.

COPPER IN WYOMING.—North and east of North

Looking North Across Open Pit of Treadwell Mine.

speaking the rock is too hard for economical hand-drilling. The substitution means a decrease in the ratio of colored to white labor. My view regarding the required ratio has gradually undergone modification, and

Platte river in east-central Wyoming is a broad, low, domal mountain mass, with a maximum height of about 6,000 ft. above sea level, which is known as the Hartville uplift and which is similar in many respects to the

Open Pit of Treadwell Mine, Showing the Orebody.

it appears to me now that the ultimate ratio will be less than 7 to 1.

An improvement means necessarily a material reduction in the number of men, white and colored, per stamp—a reduction that should, however, be met by the increase of stamping capacity required for best results. Regarding this increase of stamping capacity, if the average number of stamps were double the present number, the working cost would doubtless be 10 or 15%

Black Hills of South Dakota. Throughout this entire area copper is so widely distributed that, although no large deposit has yet been discovered, valuable beds of ore may at any time be found. The ore deposits occur in the form of fissure veins, lenticular or globular masses of ore that outcrop at the surface and pinch at slight depths, and blanket or bedded deposits. The fissure veins have not been sufficiently developed to establish their character beyond doubt.

The Treadwell Group of Mines.

By ARTHUR C. SPENCER.

*The mines of this group are owned by the Alaska-Treadwell Gold Mining Co., the Alaska-Mexican Gold Mining Co., and the Alaska-United Gold Mining Co. The mines, four in number, are known as the Treadwell, Seven Hundred Foot, Mexican, and Ready Bullion. The Seven Hundred Foot and the Ready Bullion are owned by the Alaska-United Co., though the former is leased by them to the Treadwell company.

These mines are situated on the inland side of Douglas island, near the shore of Gastineau channel, along which the workings extend for a distance of nearly 7,000 ft. The northwesternmost mine is the Treadwell, and south-eastward through the Seven Hundred Foot and Mexican properties the strike of the lode is continuous for a distance of 3,600 ft., beyond which there is an unexplored interval of 2,300 ft. between the Mexican and Ready Bullion.

Although the mining operations have revealed several separate orebodies and certain distinctions are made in the character and occurrence of the ores, the mines are all situated on the same lode and the ore is practically of identical origin throughout.

The mines of this group have yielded \$24,817,000 from

oblique to the channel, so that the outcrops of the orebodies recede from the shore as they are followed northwest. The base of the greenstone hanging wall strikes the shore of the island about one mile below the Ready Bullion mine, at first running inland and then back to a point below high water just beyond the exposure of the southernmost body of diorite in the open pits of the Ready Bullion mine. Reappearing within a few hundred feet, it bends sharply and is next exposed in the southeast pits of the Mexican mine. From this point it is traceable in a nearly straight line through the Seven Hundred Foot and Treadwell workings and for a distance of several miles beyond.

In the vicinity of the mines there are no dikes of diorite on the south side of the greenstone next to the channel, but about one mile to the northwest two croppings have been noted, and Juneau island, lying in Gastineau channel about 2,000 ft. from the foot-wall, is composed in part of similar rock, which contains some pyrite impregnations. Farther to the northwest dikes of mineralized rock apparently originally similar to this diorite are found in the vicinity of Cowee creek, where they also lie above the bed of greenstone.

Besides the mineralization in the igneous dikes, the black slate that lies on either side of the greenstone band contains occasional veins and stringer leads at several

Douglas Island, Alaska.

1882 to the end of 1905, and of this total \$17,359,811 is to be credited to the Alaska-Treadwell alone.

The Treadwell orebodies consist mainly of mineralized albite-diorite occurring in the form of intrusive dikes in black slate, the structure of which they closely follow. These slates are metamorphosed shale in which both bedding and slaty structure strike northwest-southeast and dip about 50° toward the northeast. The ore-bearing dikes belong to a series of intrusives that appear interruptedly along the strike for a distance of about three miles in a zone approximately 3,000 ft. wide. In the greater part of this intruded area exposures are few, and only small dikes are found outcropping on the side toward the centre of the island. On this side the zone seems to be irregularly limited, but next to the shore of Gastineau channel the border is defined by a heavy bed of greenstone that runs parallel with the slate and the intrusive dikes and dips with them toward the adjacent channel. Outside of this greenstone no dikes of diorite are known near the mines, though they do occur toward the northwest.

The mineralized dikes that constitute the ore occur just beneath the bed of greenstone, which thus constitutes the hanging wall both of the intrusion zone and of the orebodies. Many of the dikes of albite-diorite at a distance from the hanging wall have been greatly altered and impregnated with pyrite, though workable orebodies have not yet been discovered in them.

The strike of the different rocks is regular and slightly

points. In general these veins follow the structure of the slate. Veining of this sort may be readily observed along the shore of the island southeast of Ready Bullion creek, and it is particularly to be noted along the foot-wall of the Treadwell greenstone for a distance of several miles northwest of the mines. Assays of material taken from these veins by the writer showed values up to \$6 per ton. There has been no systematic attempt to develop them at any point, and it is doubtful whether the ore is segregated to an extent sufficient to make them profitable.

The hanging-wall greenstone forms a prominent bed about 300 ft. thick. It follows the structure of the slate. As a rule the rock is greatly altered and in places it is often schistose or slaty, but portions of it are sufficiently unchanged to indicate the original composition and structure. In the vicinity of the Ready Bullion mine the rock is granular, consisting mainly of coarsely crystallized hornblende, though it contains a great deal of magnetite and some pyrite. Northwest of the workings the greenstone is a fine-grained diabase.

The greenstone was called gabbro by Becker, who regarded it as later than the rock of the orebodies, but there is now sufficient evidence to establish the opposite age relation, and reasons exist for doubting its intrusive nature. In the open pits of the Seven Hundred Foot and Mexican mines the exposed lower part of the greenstone bed is very schistose, and this slaty rock forms both walls of the orebody. Between the ore and the black slate, which usually forms the foot-wall, is a plate or layer of

* Abstracted from "The Juneau Gold Belt, Alaska," Bulletin No. 287, U. S. Geological Survey.

chloritic schist of variable thickness, evidently identical with the schistose greenstone of the immediate hanging wall, and the latter grades off into the massive rock. This relation suggests that the locally developed schistosity of the greenstone existed before the intrusion of the diorite dikes, or was produced at the time of the diorite invasion, and in either case the greenstone must be the older rock.

The black slate, which constitutes the main country rock in the vicinity of the Treadwell mines, is a highly metamorphosed, carbonaceous, and calcareous shale of fairly uniform texture. The stratification is usually determinable from variations in color and from slight changes in the character of material, and so far as observed the bedding and principal slaty cleavage are always in accord. The cleavage of the slate is regarded as having been produced before the diorite intrusions, the direction of which it largely controls.

Classification of the Treadwell diorite is difficult, because it has been impossible to secure unaltered material. It was described as granite by Adams, but Becker gave it the designation 'sodium syenite,' to distinguish it from the ordinary syenites, which contain potassium as their alkali constituent. However, since the soda-feldspar albite, which is the characteristic mineral of the rock, belongs to the plagioclase series, and these feldspars are the distinguishing feature of dioritic rocks, he suggested the alternative name 'albite-diorite,' which is here employed, because it indicates the known relationship of the Treadwell rock with the dioritic intrusives of the adjacent Coast range.

In the vicinity of the mines dikes of albite-diorite occur in the black slate and are distributed throughout a zone about 3,000 ft. wide extending along the strike for a distance of three miles. Thus far only bodies near the hanging wall of this zone have been mined, though several others are strongly mineralized. The dimensions of the different dikes are extremely variable, the larger ones having a maximum observed width of over 200 ft. in surface exposure and in the mine workings. The sizes vary from this down to the width of one's hand. Toward the ends of the intrusive area only small dikes occur, as may be observed along the bed of Bullion creek.

The occurrence of the sulphide-bearing diorite that forms the Treadwell ore deposit has been described by G. M. Dawson, who visited the mine in 1889. This geologist states his impression that the deposit represents the upper portion or 'feather edge' of a granitic intrusion, probably contemporaneous and connected with the granites of the neighboring Coast range. The structural relations presented by this view are entirely in accord with present observations, for, while the rock cannot be strictly classed as granite, neither can a large part of the rocks which form the core of the Coast range be so classed, since their composition is usually dioritic.

In several places in the mine basalt dikes, which cut all the other rocks, have been encountered. They are narrow, usually from a few inches up to three feet, and have sharply defined walls. Locally the dikes occur in pairs, and in several places are seen to divide, particularly when they occur in zones of sheeted rock. The fissures in which they occur are transverse to the strike of the rocks and trend from N 10° W to about north and south true meridian, with a rather steep dip west. As a rule, they are not mineralized, though a small amount of pyrite sometimes appears. In several places veinlets of calcite occur along the selvage, but these are readily determinable as of later origin than the greater part of the quartz and calcite that form a reticulation throughout the mass of the ore material.

The occurrence of the albite-diorite dikes constituting the Treadwell orebodies has already been described.

The ore consists mainly of rock impregnated with sulphides, principally pyrite, and in part shattered and filled by reticulating veins of calcite and quartz, which also carry sulphides. The ore-bearing dikes are considerably mineralized throughout, and often the whole mass can be mined. Locally, however, the rock is too poor for extraction, and portions of it must be left.

Three sorts of ore are recognized by the miners—'quartz,' 'brown ore,' and 'mixed ore.' The quartz ore, which constitutes the bulk of the workable material, is essentially altered and mineralized diorite cut by a network of small veins of quartz and calcite. As a rule, its color is white or light gray, but in many places it has a greenish cast. The brown ore is derived from a comparatively small amount of productive mineralization occurring in the walls or in the narrow horses of slate, where the presence of gold-bearing sulphides is commonly recognized by a brown color. The brown material grades into the ordinary black slate, and its color is apparently due to decarbonization of the carbonaceous rock by percolating sulphide solutions. Impregnation of the slate is by no means always present, and where it occurs it seldom extends for more than 2 or 3 ft. from the walls of the main ore mass. The mixed ore, which is more abundant than the brown, is composed of slate intricately intruded by small dikes of very fine-grained diorite, the whole being impregnated with sulphides in the same way as the ordinary ore.

The value of the material mined varies from \$1 to \$5 and even \$10 or more per ton, though in the course of development a great deal of less valuable rock is extracted, and in working the open pits large amounts of worthless slate must be moved, much of which goes with the ore to the stamps. In general the average value of the rock has been a few cents over \$2 for the past two or three years. From 60 to 75% of the gold is free milling, and the concentrate, which the mill records shows to be about 2% of the material treated, assays from \$30 to \$50 per ton.

The impregnation of the dikes in which the ore occurs is, for the most part, so general and the presence of at least small amounts of gold is so constant that it is impossible to recognize any well-defined masses properly distinguishable as ore-shoots, though the gold is by no means uniformly distributed. From the assay-plan the gold does not appear to occur in any regular way, and indeed the distinction between ore and rock too lean to pay for extraction is often the matter of only a few cents. The actual differences in the tenor of several contiguous samples taken are usually much greater than the difference between the average of any block of ore and the contents of intervening masses of poor rock. In several places mere joints or seams may be noted separating the ore and the poor material, and it frequently happens that blocks of the latter, which assay from a trace up to \$1, are entirely surrounded by ore averaging \$2 or more. Structural limitations, such as joints, however, are difficult of observation, because the sides of the drifts are everywhere covered with dust.

In general the best ore is that which contains the greatest number of quartz and calcite veinlets, and though their absence is not an infallible indication of valueless material, it seems that the irregular distribution of the gold has resulted mainly from original differences in the amount of crushing and the consequent varying permeability of the rock. Where there is no metasomatic replacement of the diorite by secondary albite, the sulphides usually replace such minerals as hornblende or mica, and it is suspected that in these cases the gold content is ordinarily low.

In planning the position of stopes the assay-charts

often indicate pillars of relatively poor material, but as a rule the poor rock is not found to persist for the whole distance between two levels. The largest masses, which have been left because of their leanness, are on the foot-wall side of the south dike in the Treadwell workings,

Fig. 1. Cross-section Through Alaska-Treadwell Mine and Northern Side of Douglas Island.

but even here there are great variations in the gold tenor at different places. On the 110-ft. level all the rock was minable; on the 220-ft. level from 10 to 40 ft. of low-grade stuff was left on the floor, excepting for a distance of about 150 ft. On the 330-ft. level good ore was found up to the slate, excepting for 200 ft. along the west

an apparent gradation from the vein-matter into the wall-rock. In small specimens it is often difficult to distinguish the vein-stuff from the rock when the amount of introduced minerals is large in proportion to the mass of the matrix, though in large fragments or on the stope faces the general extent of the different portions of the ore is exhibited. The microscope shows that the merging of the veinlets with the rock cut by them is due either to penetration of the latter by calcite, which is intercrystallized with secondary albite formed at the expense of the original feldspar, or, in the case of some of the smaller veins, to the fact that albite formed in the vein or along the side of the fractures is intergrown with the feldspar of the rock, making a closely welded boundary.

In the minute veinlets quartz seldom occurs, the filling being albite with some calcite, pyrite, and occasional rutile. Where it fills narrow cracks the appearance of the albite mosaic and the manner in which it comes in contact with the walls suggest that it may have been formed by granulation of the original feldspar. To what extent this suggestion may apply cannot be determined,

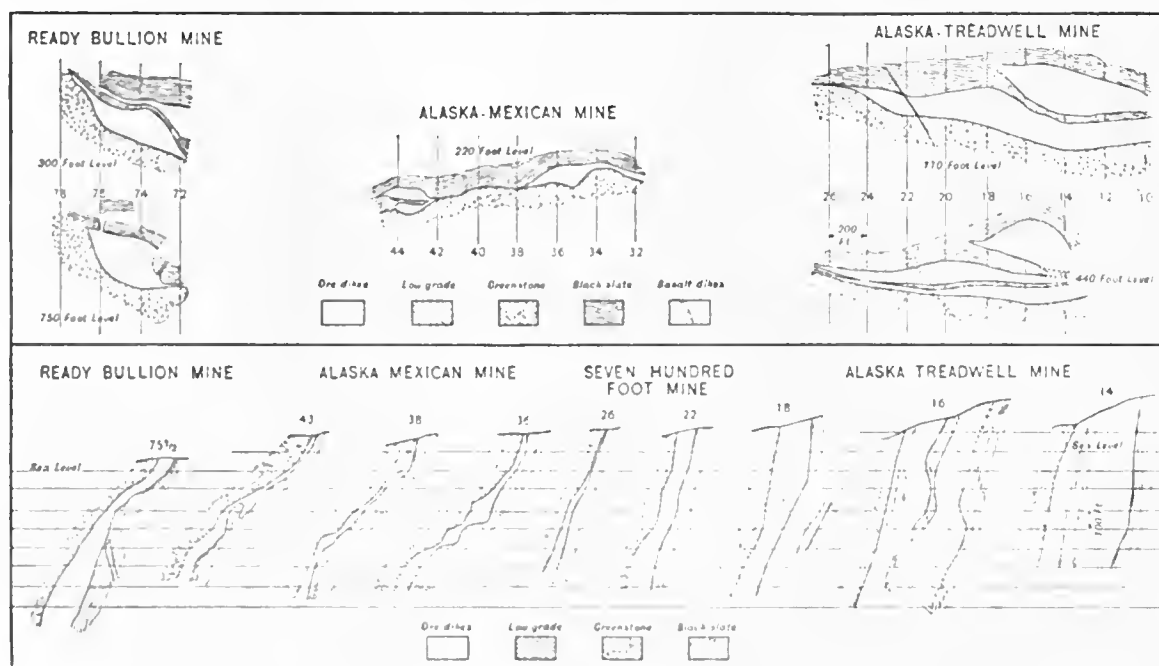

Fig. 2. Plans and Cross-sections of Orebodies in Mines of Treadwell Group.

end, where 20 ft. or so was left; while on the 410-ft. level not over half the rock assayed over \$1. The relative position of the high-grade and low-grade material in this part of the mine is shown in the plan of the 410-ft. level and in section 16 (Fig. 2).

In almost all parts of the Treadwell deposit reticulating veinlets of calcite and quartz are prominent features of the mineralized dikes. Aside from a small amount of sulphides, the veinlets are often composed entirely of calcite, but this mineral is usually accompanied by quartz, though the latter seldom occurs by itself. Albite has been noted only in fillings that are less than an inch in width, though there is every reason to believe that careful search would reveal it in small amounts in many of the larger stringers. The veinlets rarely measure more than a few inches across, while many of them are much narrower. The microscope shows the presence of minute fracturing between the veins visible to the unaided eye. The veins are usually closely spaced, and an estimate based on a study of all the mine workings indicates that infiltrated materials make up nearly one-fifth of the mass of the ore.

The boundaries of the veinlets against the inclosing rock are sometimes distinct, but in many cases there is

but it is to be noted that the calcite and pyrite of the mineralized rock never penetrate the clouded feldspars, but are always confined to these mosaics except in portions of the ore where hornblende has been replaced by sulphide. The presence of calcite and pyrite shows that there has been an introduction of material during the formation of the ore, so it may be that part of the feldspar substance was found ready at hand, while another part of it has been contributed by the mineralizing waters.

Veinlets traverse the rock in different directions, but the greater part of the filling occurs in fissures constituting two well-marked systems. One set of fractures strikes and dips approximately with the structure of the inclosing slates; the other, which is the more prominent, strikes slightly oblique to the structure of the country rocks and dips in the opposite direction—that is, toward the southwest. The fractures in the diorite have been so completely healed by the combined replacement of the rock minerals and by the deposition of vein-stuff that in blasting the ore breaks like a massive rock.

The ore dikes have been developed along the dip for a distance of approximately 1,000 ft. in all three of the mines now operated. The Treadwell workings reach

about 700 ft. below sea-level, the Mexican 600 ft., and the Ready Bullion 800 ft. In no case has it been possible to make out any progressive change in the character of the ore as depth was attained. The assay-charts show the ore in the lowest levels to be quite as good as in the upper workings, and it is evident that variations along the dip are not greater than those observed from place to place along the strike. It is true that the mine records for a period of years show a gradual decrease in the value per ton of the material which has been treated. This is especially noticeable in the case of the Treadwell mine, which has been the longest in operation, but it is the result of increasing the tonnage by mining low-grade rock, rather than an indication that the average value is decreasing with depth.

It seems fair to assume that the ore will continue to at least a considerably greater depth without important change in average value. There is nothing in the character of the ore to indicate any important secondary concentration of values by oxidizing waters near the surface. On the other hand, the characteristics of the deposits are believed to indicate that it was formed in its present condition by the direct action of ascending waters, and that practically no subsequent or secondary concentration has taken place. If this idea is correct, there can be little doubt that mineralization and the ore will continue to a much greater depth than has been reached, and it may be fairly anticipated that the limit of deep mining will finally depend more upon increased costs attendant upon hoisting and pumping than upon exhaustion of the ore.

MEERSCHAUM, which has heretofore come from Turkey, in Asia Minor, has recently been found in New Mexico, and the scarcity which has characterized its production during the past few years will, from present indications, soon be at an end. The mines are in the Diablo range of mountains, about 20 miles northwest of Pinos Altos, to which a branch of the Santa Fe railroad runs from Deming. Two veins have been stripped for 1,500 ft. each; in them there is carried, between strongly defined walls, meerschaum in widths of 20 in. The veins are vertical and give evidence that they were formed through the splitting apart of volcanic conglomerate, a theory still further confirmed by the blowouts and deposits of float that have been thus far discovered, and finally by the fact that kidneys of pure meerschaum in various sizes are obtainable from this surface material, although it has been subjected to the decomposing effects of the elements, impregnation of vegetable matter, and the seepage of other minerals in solution into it for centuries. A wagon-road is now being built from the mines to Pinos Altos, a distance of 20 miles, and when this is completed the meerschaum will be marketed.

SWISS DENATURED ALCOHOL.—The Federal Government of Switzerland has a monopoly of the alcohol-supply industry of that country. Denatured or industrial alcohol is sold by the Government at cost—about 25c. per gallon. It is prohibited to mix any substance with denatured alcohol that would counteract the effect of the denaturation or change its taste or smell. There are two methods of denaturizing the alcohol—the complete and the incomplete. The complete method is applied to spirits which are to be used for heat, light, and power purposes. This alcohol is fully denatured; pyridine is used as a base and the process is secret and frequently changed. Incomplete denaturation prevents the alcohol from being used as a beverage, but does not destroy its properties for special uses.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

The pit-boss of a mine may delegate to a miner the duty of making an inspection. And where such duty was delegated to a miner, while performing such duty, he was as to his co-workers a vice-principal and not a fellow servant, irrespective of his ordinary duty. And a miner may recover for injuries which resulted from the negligent performance of duties of the person to whom the power of the pit-boss was so delegated.

Western Coal Co. v. Buchanan, (Ark.) 102 S. W. 694. (Apr., '07.)

A mining lease provided that the lessee should have one year to explore for ore, and immediately thereafter he should commence mining operations, and if he failed to prosecute the operations, and during the remainder of the term failed to mine, for a continued period of one year, and raise the ore on which royalty was payable, the lease should be void at the option of the lessor, except as to the liability of the lessee therein. It is further provided that after one year from the date of the lease that the lessee must mine at least one thousand tons of coal annually, or pay the royalty on that amount. An action to forfeit the lease could be maintained after one year on the lessee's failing at any time to prosecute the mining operations for a year; and the acceptance by the lessor of the minimum royalty was not a waiver of the right to forfeit the lease for the failure to mine for such year.

Chauvenet v. Person (Pa.) 66 Atl. 855. (Apr., '07.)

The provisions of the Tennessee statute permitting a mine to be operated for thirty days without a licensed foreman, without being subject to penalty, was held not to give an unlicensed foreman the standing of a lawful foreman under such statute, during the first thirty days of his employment, even though he was subsequently licensed; but that until so licensed the owner or operator was in control of the operation of the mine as before the enactment of the statute, and his liability was not affected thereby.

Cumberland Coal Co. v. Gray, 152 Fed. 939. (March, '07.)

A person advanced money to purchase certain mines under an agreement that he should receive a proportionate share of the capital stock of a corporation to be formed for the purpose of operating such mines. On a failure to issue and deliver the proportionate amount of the capital stock after the corporation was organized, it was held that the person so advancing the money might have specific performance of the agreement, where it appeared that the stock had no known value and that the damages were incapable of ascertainment.

Rau v. Seidenberg, 104 N. Y. S. 798. (March, '07.)

Where unforeseen difficulties in the operation of a mine prevented the lessee from operating it at a profit or in competition with other mines in the particular vicinity, the lessee was held not liable for the payment of a specified royalty for coal not actually mined, where the lease provided that payment should be made, unless the lessee was unavoidably prevented from taking out the coal.

Wilson v. Big Joe Bloek Coal Co., (Iowa) 112 N. W. 89. (June, '07.)

A lease to mine coal and other minerals and pay royalty thereon to the lessor, provided that the mining was to be done at the lessee's discretion, and that no cessation of operations or failure of the lessee to avail himself of the privileges conferred by the lease should operate as a forfeiture thereof. This was held to be a mere option, based upon no consideration, and could be withdrawn at any time before money was expended in doing what was optional upon the part of the lessee.

Collins v. Smith (Ala.), 43 So. 838. (April, '07.)

Ore Deposits in Serpentine.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM FORSTNER.

The term serpentine is rather vague; serpentine is really the name of a secondary mineral, occurring substantially in all the varieties of rocks in which chlorite is found.¹ Under the name of serpentine are included rocks which, whatever might have been their original character and composition, now consist mainly or wholly of serpentine. They display a variety of texture according to the character of their components, and the remains of the original minerals are often present. They are the product of regional metamorphism.² It is evident that all stages of serpentinization are found, and the line of demarkation between more or less altered basic igneous rocks and serpentines cannot be drawn rigidly.

Serpentine, in a majority of cases, is an alteration product of basic igneous rocks, although occasionally of sedimentaries. This alteration, including an increase of volume, must take place in the upper zone of the earth's crust. The igneous rocks altered into serpentine are prominently the basic gabbros and peridotites.³ The gabbros are relatively high in alumina, and the peridotites high in magnesia.

It is evident that during the alteration of these rocks, an excess of alumina and magnesia may be present, which would cause the aggregation of corundum, (Al_2O_3), and magnesia, which, in the presence of the carbonic acid existing in the waters within the belt of weathering, will form magnesite (MgCO_3).⁴

Both these minerals are found in considerable masses in the serpentines, and as far as I know, occur only in those rocks. Corundum is an original constituent of igneous rocks, and its formation in serpentine may be a result of fractional crystallization in the original igneous rocks.⁵

The principal metallic ore deposits in serpentine (using the term of ore deposit in the sense of "deposits or orebodies, having sufficient development and carrying sufficient values to be commercially workable, or carrying indications that by further development, such commercially workable orebodies can probably be opened up") contain chromite and quicksilver ores, and, exceptionally, copper ores. Generally the metallic minerals are found disseminated through the serpentine their concentration occurs only occasionally, and then only associated, in the majority of cases, with a fracturing and re-cementing of the rocks.

As far as the available literature bears on the subject, the question why the concentration, by solution and re-precipitation, occurs so rarely in serpentine, does not seem to have been investigated.

J. H. Pratt has made a special study of the occurrence of chromite in peridotites.⁶ In this article Mr. Pratt calls attention to the constant association of corundum and chromite with peridotites, and offers the following explanation for the occurrence of chromite: Chromite should be regarded as having been held in solution by the molten mass of the peridotite and formed at the same time as the peridotite, crystallizing out among the first minerals during the process of cooling.

Morozewicz and Lagorio⁷ have proved that we must regard a fused mass of rock as a liquid, having similar

properties to an ordinary solution. Their experiments have shown that a molten basic glass, similar in composition to the basic magnesian rocks, dissolves alumina readily, and that upon cooling, the first minerals to separate out are corundum and spinel.

When a fused mass of rock begins to cool, the minerals will separate out, not according to their fusibility, but according to their solubility in the fused mass. The more basic minerals being the less soluble, will separate out first, and this crystallizing out from the solidifying mass would take place first on its outer boundaries. This is not the same as the differentiation of rock magmas, but is essentially the idea advanced by Becker.⁸ I do not well see the difference between fractional crystallization as herein explained and magmatic segregation, as for instance, expounded by Svante Arrhenius ('Genesis of Ore Deposits,' p. 644), and Kemp ('Handbook of Rocks,' p. 20). They are both to be distinguished from the sudden cooling of lavas, occasioning glassy groundmasses.

The peridotite belt that runs through North Carolina consists to a great extent of dunite, while northward the alteration into talc and serpentine is much more prominent. In the southern portion the peridotite occurs generally fresh at the surface, with very little serpentine. Microscopical examination shows the serpentine between the particles of dunite.

The literature concerning the origin of chromite is scant.

Hitchcock mentions⁹ chromite as occurring in minute grains through most of the serpentine, and occasionally in pockets. G. H. Cook mentions¹⁰ the presence of numerous small particles of chromite in the serpentine at Hoboken. C. D. Smith says¹¹ "chromite occurs in the chrysolite rocks throughout the entire range." J. W. Lewis states¹² that small octahedrons or rounded grains of chromite or picotite are sparingly scattered through nearly all the peridotite rocks. The same facts are mentioned in the geological reports of Georgia, Pennsylvania, and Maryland. F. D. Adams¹³ remarks: "The constant association of chromite with serpentine, which rock is a decomposition product of basic eruptive rocks, rich in olivine, points very strongly to the probability of this mineral also being a product of the differentiation of basic igneous magmas during cooling, and before their solidification and alteration to serpentine."

Glenn¹⁴ says: "It is an impressive fact that chromite iron is found in serpentine only, or in some rock akin to it, and like it metamorphic."

Mr. Pratt describes the occurrence of the chromite in North Carolina as follows: The chromite occurs in the peridotites mostly in grains and crystals, and imbedded masses situated near the boundaries of the lenticular bodies of peridotites, not in well defined veins, but in masses and pockets, which have "apparently" no relation with each other.

Where larger deposits of chromite occur there has been little or no corundum found, and the reverse, where corundum is abundant little or no chromite is found.

The chromite shows little or no crystalline structure.

The theory of fractional crystallization accounts for all phenomena of these chromite deposits.

In the North Carolina occurrence three features are apparent, namely, the intrusion of peridotite in gneiss, the formation of the chromite zone, and the apparent isolation of the chromite deposits by erosion.

¹⁴ 17th Annual Report U. S. G. S., Pt. III, p. 164.

In his discussion, Mr. Pratt does not touch the question of re-distribution of mineral components, which accompanies the alterations, inevitably taking place in the upper zones of the earth's crust. Accepting his statement that the peridotites in North Carolina are fresh, the presence of serpentine in dunite, mentioned by him, indicates that this alteration process is going on. The occurrence of chromite in the serpentines, mentioned by him, must also be taken into account.

The absence of concentration of the chromite may be due to the fact that chromite is a very stable oxide, so that no alteration product of chromite is known, which would indicate that the solutions percolating through the belts of weathering and of cementation are not able to cause the concentration of the chromium minerals, by solution and re-precipitation, as is the case with the minerals of other metals.

The quicksilver ore deposits, especially those of the Coast Range of California, are associated with serpentine. The latter are nearly exclusively deposited in pre-existing openings, and are closely related to Tertiary or post-Tertiary eruptions.¹⁵ This ore deposition was also closely associated with a silicification process, during which the silicious solutions permeated fractured rocks, principally serpentine, dissolving the bases and depositing opal. The quicksilver ore deposits are formed by precipitation from solutions.¹⁶ As this precipitation process took place in the upper zone of the earth's crust, principally in the belt of oxidation, the sulphides of other minerals were probably leached out. Prof. de Launay states regarding this point, that many of the former quicksilver deposits, which occur chiefly in recent rocks near volcanic eruptions, have disappeared from older ranges, partly destroyed by erosion.

The presence of cemented and indurated sandstones, chalcedonite, phthanite, and serpentine may represent various phases of the process of cementation in the belt of fracture. The cinnabar forms in the cracks, seams, and fissures of the silicified material, and its source is apparently extraneous to the serpentine, or its original rock.

As far as I have been able to ascertain, the only rich copper ore deposits in serpentine, as yet found, are situated in northern Italy.¹⁷

The mineral serpentine is an alteration product of various minerals, and consequently the rock 'serpentine' is the alteration of various rocks, both igneous and sedimentary. The igneous rocks, from which serpentine is an alteration product, often carry metallic minerals, but apparently the alteration process into serpentine does not favor a sufficient aggregation of these metallic minerals to form orebodies; and apparently the serpentine rock is not a favorable material for the trunk channels of circulation, in which solutions deriving their metallic mineral components from other sources, would find favorable conditions for deposition. Consequently, most generally the metallic minerals are found disseminated through the serpentine, or aggregated into small masses.

In 'The Copper Deposits of the Encampment District, Wyoming,' by A. C. Spencer,¹⁸ it is stated: "No important ore occurrences have been noted in this rock (serpentine), but sulphides are found enclosed in it, in some places." This is the only occurrence of copper ore in this country of which I find mention.

According to the Grass Valley special map of the Survey, there is a system of more or less parallel veins of

gold ore in serpentine in that district. Unfortunately my notes and library were burned in the San Francisco fire; both reference libraries in this city have been destroyed, and by reason of repairs being carried on in the Ferry Building, the library of the State Mining Bureau is largely inaccessible. In the folio, the relation of the serpentine to the enclosed quartz veins are not discussed, but I am sure that in Lindgren's report on this district¹⁹ this point will be discussed. In the above cited folio, Mr. Lindgren, speaking in a general way on the gold-quartz veins, states that these were formed in fractures, which are posterior to the general metamorphism of the country. The only further reference on this subject, at my disposal at the present moment, is in 'Genesis of Ore Deposits,' where Mr. Lindgren mentions the fact that in the Grass Valley district, the serpentine adjoining the Idaho vein is transformed into magnesite, mixed with quartz and some residual serpentine. This occurrence is similar in nature to that wherein I consider the quicksilver ore deposits of the Coast Range have been formed.

In my report on the copper occurrence on the Nicolini ranch in Napa county, California, I suggested as the possible genesis of the native copper aggregates found in the serpentine, that the copper sulphate in the percolating solutions had been precipitated by ferrous salts derived from the ferro-magnesian silicates, during their alteration into serpentines, chlorites, etc. Clarke and Diller²⁰ attribute the concentration of nickel to a similar process. They consider that the nickel was originally a constituent of the olivine, and separated out during the process of the alteration into serpentine. This nickel was taken into solution by the percolating waters in the zone of rock decay, and precipitated as a coating on the walls of cracks and in small veins.

CARNOTITE IN COLORADO.—The name carnotite was applied in 1899 to a canary-yellow ochreous pigment that was found impregnating a silicious sandstone in Montana county, Colo. This mineral is a source of the rare elements uranium and vanadium, and tests have also shown that it contains the still rarer element radium. Uranium and vanadium have attracted much attention in recent years, uranium being used as a pigment in photography, and vanadium being added to steel to increase its tensile strength, elasticity, and ductility. Uranium also has the property of increasing the hardness and elasticity of steel and of aluminum, but has not yet been much used for this purpose. Carnotite has been discovered at a number of places in Colorado and adjacent parts of Utah. Particularly interesting deposits are found near the valley of Coal Creek, about 14 miles northeast of Meeker, in Rio Blanco county, in the northwestern part of Colorado.

AUSTRIA-HUNGARY MINING.—The value of minerals produced in Servia in 1905 was \$465,052, of which \$309,984 was coal, \$50,299 gold, and \$31,614 lignite. By a special law the Government is the owner of the under-soil and makes all the regulations for prospecting and mining. The right to prospect is for one year and can be renewed. Mining concessions are granted for 50 years to those who prove that the territory can be exploited, that they have sufficient capital to make a success of the project, and that they or their employees have the necessary mining knowledge. After 15 years of uninterrupted work the person receiving the concession becomes the proprietor. A yearly fee of \$2.31 for each 100,000 sq. m. (119,000 sq. yd.) of a concession is charged and one per cent of the total receipts.

Mineral Land—An Important Decision.

We publish herewith the text of a letter from the Secretary of the Interior to the Commissioner of the General Land Office. It reviews litigation over certain mineral tracts in Placer county, California, and it reverses finally a decision of the Commissioner in regard to the conflicting applications for timber-land.

Five years ago some timber lands were located on the ridges of the Forest Hill divide, in Placer county. This is a region famous for its 'deep leads,' that is, ancient alluvial channels now covered with lava. In these gravel deposits successful mining has been conducted in a systematic manner for thirty years or more, and claims were located along the supposed course of the old river-beds. Of course, the exact position of them could not be ascertained beforehand, and therefore most of the ground located bore no evidence of its mineral value. In the same way, the existence of oil is not often indicated by the surface and until bores intercept the productive stratum, a potential oilfield looks like anything but the place for a mineral industry. In the case of oil, it has been decided that pending the exploration and testing of land supposed to be valuable for this mineral substance, the ground can be held under mineral location. The decision of the Secretary of the Interior in the two cases referred to in the subjoined letter is in accord with the spirit of the law and will be highly gratifying to those engaged in this class of mining.

The protestants in the above case were Frank A. Leach, president of the Eureka Con. Drift Mining Co., and Charles F. Hoffman, representing the French company operating at Red Point. Mr. Leach is the present superintendent of the San Francisco Mint; he has been selected to succeed Mr. George E. Roberts as Director of the United States Mint. Mr. Hoffman is an engineer of reputation and one of a family long identified with progressive mining methods in California. The letter follows:

DEPARTMENT OF THE INTERIOR,
WASHINGTON, May 2, 1907.

Alfred Dixon, et al. }
v.
Byron I. Taylor, et al. }

The Commissioner of the General Land Office:

SIR:

November 24, 1902, pursuant to the Act of June 3, 1878 (20 Stats., 89), timber-land applications for tracts in T 15 N, R 12 E, M. D. M., Sacramento (California) land district, were filed as follows:

- No. 1,791, by Byron I. Taylor for NW 1/4, Sec. 8.
- No. 1,792, by Ibo I. Heyen for S 1/4, SW 1/4, NW 1/4, SW 1/4, NW 1/4, Sec. 20.
- No. 1,793, by Charles A. Shannon for E 1/4, SE 1/4, S 1/4, NE 1/4, Sec. 20.
- No. 1,794, by William Esterbrook for W 1/4, SE 1/4, NE 1/4, SW 1/4, SE 1/4, NW 1/4, Sec. 20.
- No. 1,795, by Charles C. Root for NE 1/4, Sec. 8.

Notice of the submission of proof before the local officers on March 5, 1903, was given, each timber land claimant designating the four other applicants as his witnesses. On the day fixed proof was taken in support of each application and each applicant, and his two witnesses were cross-examined by a special agent. The proofs submitted appear to be in the usual form and indicate *prima facie* that the tracts sought are of the character and condition contemplated by the timber-land act. The purchase money for the land was tendered, and in each case refused because of the pending protests mentioned below.

On March 5, 1903, and prior to the submission to the

timber proof, Alfred Dixon and seven others filed their verified protests, one against each timber-land applicant but all substantially similar in form and contents, and Frank A. Leach, president of the Eureka Consolidated Drift Mining Co., joined with Charles F. Hoffman, agent of the Societ  Anonyme des Miners de Golden River, in filing two protests essentially similar, one directed against timber-land application No. 1,791 and the other against application No. 1,795. The recitals contained in the protests are lengthy, but the protestants in substance and effect allege that the tracts applied for contain gravel deposits carrying gold and quartz veins or lodes bearing gold and silver in paying quantities, and are more valuable for mineral than for timber or agricultural purposes; that portions thereof are embraced in mining claims; that the tracts are situated in a mineral belt and in the midst of one of the richest mining districts in the State, and that the timber applicants are not applying for the land in good faith for their sole use and benefit, but for and in the interest of an association, or corporation, with the design of fraudulently acquiring mineral land. The protestants asked for a hearing.

July 13, 1903, the hearing commenced, all parties being represented by counsel. Ten witnesses were produced by the protestants and examined. The protestees presented no witnesses but rested their case upon their timber proof which was specially offered in evidence and objected to by the protestants on the ground that no opportunity had been offered for cross-examination upon the non-mineral return of the land in question, and upon the cross-examination of protestants witnesses.

October 12, 1904, the receiver of the local land-office recommended that the plats applied for situated in the N 1/4, Sec. 8, and in S 1/4, N 1/4, Sec. 20, be adjudicated mineral in character, and that the application as to said tracts be rejected, while the Register recommended that all the land applied for be adjudged mineral and all the applications be rejected.

Both parties prosecuted appeals to your Office, which on October, 1905, decided that the lands applied for were non-mineral in character and were properly subject to disposition under the Timber Act; and it was stated that in the event such decision became final, and in the absence of other objections, the timber proofs offered would be accepted, and upon proper payments final receipts and certificates would be issued. The protestants have appealed and contend in substance that the decision of your Office is unsupported by and contrary to, the evidence.

The record, which has been fully examined, is too voluminous and the evidence enters into details too numerous, to warrant the undertaking of an extended discussion. Miners of the vicinity, mining engineers, and experts testified, and among them was Ross E. Browne, an eminent geologist and an authority on deep-channel placer deposits of the character here involved.

By the evidence adduced, it is shown that the lands in Sec. 8 are upon the western slope of the Sierra Nevada mountains, upon the Forrest Hill divide, an extensive ridge consisting of a thick volcanic cap overlying valuable auriferous placer deposits in gravel beds and channels of an ancient river valley, the boundary rim of which has been carefully determined. There are many paying mines within the ridge in the near vicinity. Above the land here involved four deep gold-bearing channels and a large area of an underground auriferous gravel bed have been worked by means of tunnel and drifts; while below, three well-defined ancient channels have been capped and developed, besides a number of gravel beds of small area. It is clearly indicated that these gravel beds, owing to their extensive distribution, are but portions of a general deposit existing throughout that region of the

divide, and that some, if not all, of the gravel channels mentioned, owing to their grade and general trend toward the land in question, must, in their onward courses, pass through, and exist beneath, the north half of Sec. 8. From that portion of one of these channels in the southern part of Sec. 8, not less than \$100,000 in gold has been extracted. This channel has been worked for many years and has always paid. The main drift thereon is almost four miles in length and is directed toward the eastern portion of the N $\frac{1}{2}$ of Sec. 8.

The Colfax folio of the Geological Survey, which was received in evidence over the general objection of the protestees that it was incompetent and irrelevant, but which the Department believes may properly be considered, deals with the area in which the land in controversy is located and is corroborative of many points of the testimony. In the folio, geologist Lindgren states:

"The fluvial origin of the gravel channels and the general disposition of these ancient rivers are not theories; they are facts convincingly and completely proved. The remarkable absence of faults over the western slope has been a great aid in the interpretation of the gravel channels."

In view of all the features of this case disclosed by the evidence, taking into consideration the geological formation, the disclosures of valuable deposits in the adjoining and surrounding lands, and the general trend and pitch of the known channels toward these tracts, together with the essentially similar and identifying characteristics of the entire divide, the Department is clearly of opinion that the N $\frac{1}{2}$ of Sec. 8 is actually mineral in character and valuable for its deposits of placer gold and therefore not subject to disposition under the provisions of the Timber-land Act. As to this land the decision of your Office is reversed.

The tracts in Sec. 20 embraced in the timber-land applications about two miles directly south of the land involved in Sec. 8, are shown to be situated upon a southerly projecting spur of the divide, and are not covered by the lava cap. After a careful consideration of the evidence, the Department is of the opinion that as to these facts no such showing of the existence of a valuable mineral deposit has been made as will defeat the timber-land application. As to the land in Sec. 20 the decision of your Office is accordingly affirmed.

The papers are herewith returned for further proceedings in accordance with the views herein expressed.

Very respectfully,

(Signed) J. R. GARFIELD,
Secretary.

PROTECTIVE PAINT.—The majority of authorities acknowledge that a linseed oil paint affords the better protection for structural steel, metal, and wooden surfaces. The oil paint is also more economical by reason of its ease of application and better covering power. The life of the oil is the life of the paint and on the life of the paint depends the protecting quality. To further these ends the best boiled linseed oil must be used and inert pigments, that is, pigments that have no chemical action on the oil. The prevailing conditions of nature only too soon perform this destroying feature. The two pigments that today are being used successfully in protective paints are silica and flake graphite. The silica is inert, unaffected by heat and gases and gives the paint a good heavy body. The graphite is light, flake-like in formation, forming a compact shield-like surface, possesses great lubricating qualities which afford an easy application of the paint, is unaffected by heat and gases and when properly mixed with the silica and linseed oil, adheres to the surface and forms a protective coating.

Big Nuggets.

The *Australian Mining Standard* gives a list of the nuggets recently found at Poseidon, a new goldfield in the Tarnagulla district of Victoria. This has caused much excitement in Australia.

Altogether no fewer than 77 nuggets have been unearthed at a few feet from the surface. The principal lumps were: 953 oz. gross, 703 oz. net. There are 15 over 80 oz. gross. They weigh 953 oz., 675, 502, 387, 373, 252, 206, 152, 148, 146, 127, 104, 87, 86. Recent yields from puddling operations are 21 loads for 38 oz., 12 loads for 14 oz., 18 loads for 19 oz., 16 loads for 14 oz., 12 loads for 8 $\frac{1}{2}$ oz., 18 loads for 12 $\frac{1}{2}$ ounces.

Reporting on the field, A. M. Howitt, of the geological branch of the Victorian Mines Department, says that the shallow sinking is in dark brown surface soil and clay, and it was in this ground that the largest nuggets were found. The Poseidon, weighing 953 oz. gross, discovered by Woodall and party on December 12, 1906, was perched two inches above a conical bump, and within 10 inches of the surface. The Christmas Box, 373 oz.; the Hazel, 502 oz.; Georgina, 98 $\frac{1}{2}$ oz.; the Leila, 675 oz.; Federal, 387 oz.; and a small specimen of 21 oz., were all discovered in this surface clay, and a few inches off the bottom.

The gross weight of these few nuggets, together with a little gold obtained in addition, would total just over 3,000 oz., taken from a length of 84 ft. measurement between the two extreme nuggets. Of these, Smith, Stephenson, and Rogers obtained 1,672 oz., which yielded 1,382 oz. on smelting. This claim has given £1,900 per man, and has been, so far, the richest claim on the rush.

The next rich claim, and the one where the first shafts are seen, is that of Jackson & Hughes. Here the ground is 8 to 10 ft. deep, and the sinking of red sand, clay, and gravel occurs in a gutter with a somewhat bumpy bottom. This claim has yielded several large nuggets, among them being the Little Jack, 252 oz., and the Little Ben, 152 oz. The larger nuggets were all up from the bottom.

The next of importance is Wragge Bros.' claim. Here the sinking is in red sand and rubble of slate and sandstone was about one foot of white and red puggy seams, then one foot of sand and clay with floating pieces of slate and sandstone, and on the bottom white clay and angular quartz. The gutter containing the best gold is only about 15 ft. wide, and shows more quartz. Among the large nuggets from this claim may be mentioned the Port Arthur, 206 $\frac{1}{2}$ oz. Nearly all the nuggets were on the bedrock. Cox & Newitt's claim has had consistent yields, and the sinking is similar to Wragge Bros.' claim. The largest nugget is the Shellback, 127 $\frac{1}{2}$ oz. gross, containing much quartz.

On the whole, the gutter is narrow, but very rich in the shallowed claims. It has a bumpy bottom of Ordovician slate and sandstone, and many small turns along its course. The nuggets have been generally found up from the reef-rock and mostly on the north side of the gutter. In the shallow ground to the south of the main gutter several nuggets have been found in the dark-brown surface clay. These outside nuggets are scattered here and there, and so far not in relation to one another, as they would be if in another gutter. The nuggets, Mr. Howitt says, should not have traveled far from the original quartz veins, which should occur in the Woolshed Hill belt. This belt shows nice pitted green and other slates and sandstone of Ordovician age, fissured with large quartz bodies, showing lime, soda, feldspar, and indicating the close proximity of an igneous dike, which may be traced later on near the Woolshed reef.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

ORE-ROASTING PROCESS.—No. 859,420; Arthur R. Wilfley, Denver, Colorado.

A process of roasting ore preparatory to magnetic separation, consisting in subjecting the ore particles while falling, to sufficient heat for roasting purposes, cooling the ore particles while in a disseminated state, sufficiently to overcome the clinging tendency, by bringing the said particles in contact with a non-liquid cooling medium, and causing said particles to be removed from said medium as fast as they fall, whereby the medium is maintained in a condition to effectively act on the successively falling particles.

STAMP-MILL.—No. 859,629; Joseph F. Symons and William H. Paull, Lake Linden, Michigan.

In apparatus of the class described, a cylinder having upper and lower heads, means for controlling the admission and exhaust of an operating fluid to the lower portion of the cylinder, a by-pass having a controlling valve, and a check valve, said by-pass being arranged to admit a portion of the fluid from the lower to the upper portion of the cylinder, an exhaust pipe leading from the exhaust port, a valve casing in said exhaust pipe, a pipe placing the valve casing in communication with the upper part of the cylinder, and a three-way cock in the valve casing for con-

trolling communication with the upper part of the cylinder and the exhaust.

ORE CRUSHER AND PULVERIZER.—No. 859,835; Adolph J. Petter, Los Angeles, California.

A crushing and pulverizing apparatus, the same comprising a suitable base, a central rotatable shaft, a spheroidal shell secured thereon, a crushing jaw secured to the shaft above the said shell, an idle eccentric on the upper end of the said rotatable shaft, an outer spheroidal shell inclosing the inner spheroidal shell, a circular die ring secured to the lower edge of each spheroidal shell, a crushing jaw secured to the upper edge of the outer shell, an ore hopper carried by said crushing jaw, a spider forming connection between the outer crushing jaw and the central shaft, the idle eccentric working within the hub of said spider, and means for adjusting the outer crushing jaw and its connected parts vertically relative to the central rotatable shaft.

CONCENTRATOR.—No. 853,459; John F. Isbell, Denver, Colorado.

A riffled concentrating table having a vibratory movement in the direction of its length, the riffles also extending longitudinally of the table, the vibratory action of the table being adapted to cause the material to travel from the head toward the tail of the table, the latter consisting of sections arranged at different elevations and in stepped order, the head section of the table being highest and so on toward the tail of the table, each table section being provided with a cut off adapted to remove a suitable depth from the top of the material under treatment.

LINING FOR PEBBLE-MILLS.—No. 858,129; Max F. Abbe, New York, New York.

A cylindrical pebble mill provided with a number of natural lining stones each embedded at its sides, ends, and back in a coat of hardened cement, and means for securing adjoining coated stones to each other and also to the mill.

An Improved Timber-Framing Machine.

The accompanying illustration shows a timber-framing machine of a type furnished to some of the largest mining companies of the West. The following description will make clear the construction and operation of this labor-saving machine, the purpose of which is to reduce the cost of framing either round or square timbers for mine use.

A heavy finished iron column forms the bed on which the various parts slide when it is desirable to change the length of the timbers. This column is held by cast-iron boxes and is prevented from turning by steel pins. The parts shown on the right are set and remain stationary except in changing the sizes of the tenon. Those on the left are connected by threaded rods and can be moved together by a screw inside the column, so as to shorten or lengthen the timber; they can be adjusted to suit the tenon desired and to line up the saws. The vertical saw-arbors are driven by quarter-turn belts from the counter-shaft and have a number of collars by which the saws can be set as desired. The horizontal arbors are mounted on a swinging frame, by adjusting which these saws are made to line up with those in front. The frame has also a side movement on its spindle, which is clamped by the cap-bolts. This change can be effected without altering the belt, as will be seen by tracing its course from the top of the driving-pulley to the upper-saw pulley, around the small pulley on the adjustable counter-shaft just behind the machine, to the lower-saw pulley and return to the driver.

The various parts mounted on the column are prevented from turning by gibs, keys, and set-screws, in addition to which the main frames are provided with jack-screws to stiffen them. The illustration shows the method of holding square timbers, but, by a quick change in the chuck-jaws,

round timbers, also, from 8 to 18 in. diam., can be clamped. The chucks are made entirely of steel, and have teeth by which they are rotated 90° by an air-actuated rack and piston. The chuck and its cylinder are mounted on a slide, on the under side of which is a rack operated by a pinion on the long shaft that passes through the frames. This shaft can be rotated at will by means of the air-cylinder shown on the right.

With the saw in operation the timber is placed in the jaws, the chuck is closed and locked, the clamp-screws set down, and air is admitted to the large cylinder, causing the timber to pass through the saws. It is then returned, and air admitted to both small cylinders, causing the chucks to rotate 90°, when the second cut finishes the work. The valves controlling the admission and exhaust of air to and from the cylinders are placed in a position convenient to the operators. The question of lubrication of the rapidly revolving saw-arbors has been carefully worked out, each bearing having a sight-feed lubricator placed in plain view. All racks and pinions are steel and have cut teeth. Saw-guards are provided to cover the horizontal saws and end-gauge for setting the timbers.

The particular machine shown was made to work timbers from four to nine feet long between shoulders, 10 and 12 in. square; and round timbers from 8 to 18 in. diam., all of which sizes can be varied to suit the case.

These machines have been in operation, and very successfully too, at the Speculator mine of the North Butte Mining Co., and at the Original Con. Mining Co.'s saw-mill at Butte, Montana. The operation of the latter, we are informed, costs \$7.50 per shift for the labor of two men, plus the 30 h.p. required to operate it, and is framing completely 500 girts, or 450 caps, or 400 posts (all round or square timber) per shift of eight hours.

When the timber is delivered and taken away from the machine automatically, as at the Original Co.'s mill, likewise at the Speculator, the actual cost of framing with the machine is 2½c. per piece. When supplied with automatic handling devices such as live rolls etc., as is the usual practice, the timber is being framed, including the unloading of the timber from the cars, and the stacking of the finished timber in the stock piles, for six cents per piece.

Framing machines are now being built for the Red Metal Mining Co., and the Anaconda Copper Mining Co., and are nearly ready for delivery. These machines will work up to 24 in. round timber. An I-beam supports the back ends of the rails, and the drums are arranged so that the adjustable side of the machine can be set while in operation. These are also made heavier in all respects than heretofore. The principal features of this machine are fully covered by patents, Joshua Hendy Iron Works, of San Francisco, being the manufacturers.

Commercial Paragraphs.

THE San Francisco office of the Sullivan Machinery Co. is at 26-28 Fremont St. Howard T. Walsh is the manager.

THE MINNEAPOLIS STEEL & MACHINERY CO. has opened an office at 352 Phoenix Bldg., Butte, Montana, under the management of J. E. Lanning.

THE Isthmian Canal Commission has decided that the walls of the canal, where it passes through rock, shall be channeled. This includes almost all of the 'wet prism' in the Culebra division, nine miles long, and also the walls of the locks at La Boca and Mira Flores. The advantages to be gained from channeling are several: the resulting wall is solid and unbroken by explosives, and is cut exactly to the surveyed line, no subsequent trimming or filling being needed, as in the case of a wall cut by drilling and blasting. For this work the Commission has ordered 24 Sullivan Class Y-8 channelers, fitted with air reheaters. This machine is similar to the Sullivan channelers used on the Chicago drainage canal and its extensions. This is the largest single order for channeling machines ever placed for either public or commercial purposes.

Editorial.

THE MEETING of the Lake Superior Mining Institute has been indefinitely postponed, on account of the strike on the Mesabi range.

COPPER STATISTICS show that Arizona is pushing ahead of Michigan, and threatens the leadership of Montana. The figures collected for the Geological Survey by Mr. L. C. Graton appear elsewhere in this issue.

ANYTHING that Dr. R. W. Raymond writes is interesting whether it deals with Job or the Apex, but when he is condensing a large mass of general information and bringing it to bear on a special point, he demonstrates the qualities that have made him an engineer and an editor, a journalist and a lawyer. The article on Jamaica will be appreciated by our readers. It reminds one of Geikie's delightful writings on the scenery of Scotland as determined by geological structure, but it has a trenchant vigor that the great geologist might well envy. It is a fascinating subject, for no observant man can fail to be impressed with the interplay of physiographical and economic conditions. The explanation by Dr. Raymond gives geology a vividly human interest, and suggests similar considerations in regard to other countries—the United States, for instance. The bleak coast of New England, the barrier of the Alleghanies, the Western plains, the ramparts of the Rocky Mountains, the deserts of the Great Basin, the Sierra Nevada, and the fruitful valleys of California, all in turn determined the character of the successive waves of immigration that made the American nation. Beneath the inequalities of the surface and the climatic conditions were geological facts, fixed before the coming of the first pioneer of a new people.

FROM New York there come, as our letter from there recites, various rumors concerning the Guggenheims and their relations with J. P. Morgan, the Standard Oil Company, and other financiers. We hope sincerely that the whirligig of speculative finance will not land the Guggenheims in the lap of 26 Broadway, for much as we may regret some of the recent performances of the family identified with the Smelter Trust, we would be sorry to see the smelting industry dominated by H. H. Rogers and his coterie of predatory promoters. That would be a change much for the worse. Any further concentration of power in Wall Street will be to the injury of the mining industry, which is already irritated by the feeling that its metal markets are subject to manipulation. In regard to consolidations of capital in general, we can say that they are inevitable and regrettable. The energetic and rapacious promoters of big undertakings find it convenient to co-operate; there is a "community

of interest" followed by a "gentleman's agreement," whereby the great resources of nature become controlled by a few. It does not always work, for nature is more generous than man, but until the monopoly becomes acute public opinion is slow to act and high finance goes unhindered on its gilded way.

REFERRING TO the article by Mr. Ross E. Browne on 'Costs on the Rand,' in our last issue, it is interesting to note that the chairman of the Rand Mines, Ltd., admits that "the cost of production at present is too high to allow of the remunerative investment of money on the average yield of the gold-bearing area of the Witwatersrand." In 1906 thirty-nine companies paid £5,565,972 in dividends, the market value of the mines owned by these companies was £56,305,227 (on April 2, 1907), and the estimated life of the mines at the present rate of extraction was 12.66 years. In order to redeem the market valuation, it is necessary to set aside £3,728,368, accumulating at 3%, compound interest, and this without allowing for interest on the investment. On these figures the return to investors is less than $3\frac{1}{4}\%$, indicating that the market though depressed is not yet on bedrock, for even the most assured form of gold mining should pay 5% after allowance for amortization of capital. It is the slow recognition of this fact that has saddened the Kaffir circus.

OUR esteemed contemporary at London, *The Mining Journal*, publishes an interesting resumé by Dr. Malcolm MacLaren of the information obtainable concerning the goldfields of Tibet. Even before the Welcome there were great nuggets, for it is recorded that Genghis Khan sent one to the Sultan Mohammed "as big as a camel's neck." This came from southwestern Tibet, a region never yet explored by any modern engineer or geologist, despite recent military expeditions upon the Roof of Asia. The best account available is that of a Hindoo explorer employed by the Trigonometrical Survey of India. This native, a prototype of Kipling's 'Kim,' penetrated the highlands of Tibet in 1867, reaching one of the goldfields, where an excavation one mile long was the scene of rudimentary alluvial mining. This was Thok-Jalung, at 16,330 feet above sea-level. It was so cold there that the natives pitched their tents in pits seven or eight feet deep, thus suggesting the story of the gold-digging ants mentioned by Herodotus. Other diggings, at 15,280-ft. elevation, were visited by this native explorer and in the Daurakpa region the mining people lived in caves, as a means of protection against roving brigands. The descriptions suggest deposits of cemented gravel. The goldfields reported last year by Sven Hedin are the northern extension of the districts just mentioned. It is apparent that the gold is widely spread over a lofty wind-swept region, the climate of which is severe. Compared to Tibet, Alaska is a health resort. As yet there is no confirmation of a richness sufficient to compensate for the remoteness, inaccessibility, and inclemency of this Asiatic goldfield.

Gold Mining Reviewed.

GOLD MINING in its world-wide aspect is discussed in this issue by Mr. J. H. Curle with an authority that will be unquestioned. There is no one with so intimate an acquaintance with the scattered goldfields of the world and no one who being possessed of the facts is likely to state them so frankly. In regard to the Rand, Mr. Curle is in the ungracious position of "I told you so" and it argues some forbearance on his part that he does not dwell on the warnings he made in *The Economist* several years ago, at a time when a rosy hue suffused the Kaffir market. In his criticism of the expenses due to the elaborate direction of affairs at the head offices and the apparent extravagance of directors' salaries as compared to the close shaving of costs at the mines, he touches a vital spot. The thrift of directors in regard to the staff at the mine and mill as compared to the fees paid to ornamental boards in London reminds us of the patriot who was willing to sacrifice all his mother-in-law's relatives for the good of the country. In regard to Chinese labor, Mr. Curle supports the mine operators, that is, his views are wholly divorced from politics or a half-informed philanthropy; he discusses the problem solely as belonging to the domain of economics. The labor question is facing us at every hand, it is difficult enough, and in the solution of it good sense is more valuable than sloppy sentiment.

In regard to American gold mining, we note that Mr. Curle believes in Nevada and prophesies a great future for that State. In this expression of opinion, as in the emphasis laid upon the evils of over-capitalization, we cordially agree. Gold mining in Nevada is likely to suffer as much from the inflation of stocks representing splendid mines as she has suffered from the sinking of money into worthless schemes. Between these two extremes of financial chicanery, the speculator is in constant danger and if the industry that has made such splendid mining districts as Goldfield and Tonopah is to enrich the community in a legitimate way, it will be done by avoiding practices that disgraced the Comstock.

A bird's eye view of gold mining today presents one particularly satisfactory feature; we refer to the finding of rich ore on the deep levels of two or three famous mines. Our London correspondent tells us that a 4-ft. vein of 17 dwt. ore has been cut in the Champion Reef mine, on the Mysore goldfield, by a vertical shaft at a depth of 2,405 feet, which is 160 feet below any existing workings. The Champion Reef is one of the great gold mines of the world, for it produces about \$3,500,000 per annum. At El Oro, in Mexico, the El Oro mine has become rejuvenated by the discovery of rich sulphide ore at 1,000 feet after an interval of acute impoverishment below 400 feet, this being the lower limit of profitable oxidized ore. A discovery such as this is of immense importance to mining at large; for it is not too much to say that any company lacking working capital could never have faced the expense incurred in the exploratory work that has been rewarded by this important development. Similarly, the showing at 1,900 feet in the Great

Boulder Proprietary at Kalgoorlie is most encouraging. Thus three great goldfields—the Kolar, El Oro, and Kalgoorlie—are illuminated by news of a character that makes glad the heart of the miner.

The Verdict at Boise.

THE ACQUITTAL of William D. Haywood by the jury at Boise City is an event of importance, for it is likely to have political consequences. Like others who have taken a keen interest in the labor troubles that have occurred in Colorado and Idaho during the last ten years, we followed the trial from day to day and read the evidence as reported in the press, together with the speeches of opposing counsel. Whatever our own deductions, we accept the verdict unreservedly, believing that the support of the jury system is more important than the conviction of any supposed criminal. It is apparent from the acquittal that the legal evidence was insufficient to prove the case against Haywood. On the whole the trial leaves a mixed impression. There was perjury on both sides, most of the witnesses were untrustworthy, the issue was befogged by appeals to prejudice, and finally the trial closed with a speech—that by Mr. Clarence Darrow—so obviously meant as an address to anarchists all over the country that it amounted to contempt of court. This scurrilous tirade, in its disgusting effrontery and its inflammatory references, was a disgrace to any bar of which the lawyer might be a member. Nevertheless the trial was conducted with a dignity and fairness creditable alike to judge and jury; it has proved the falsity of the clamor that the prisoners were being “railroaded to death.” Pettibone remains to be tried. Moyer is out on bail and Haywood is free. It is well; for there is not sufficient evidence to convict the two leaders, but if they suppose that the country at large considers them as martyrs to the cause of labor, they will be undeceived. As the red rag of anarchy is waved high in jubilation, those who owe fealty to the flag of their country will know what such rejoicing means, and many thousands who knew not the policy of the Western Federation of Miners have seen it exposed during the course of the trial. The exhibit of incendiary literature published officially by that organization will have opened the eyes of people who may have thought that Moyer and Haywood were merely leaders in a social movement deserving of a free field. It is apparent that they were not, that there was an inner ring with unbounded power to swing the Federation and to use it for their own purposes, which were not always those of the members. Legal conviction they have escaped, but moral blame for inciting riot and violence they will receive from the larger jury that has been trying them during many weeks, not in Idaho alone, but in every State of the Union.

It is a sad story that we have seen told at Boise. Smoldering class hatreds and despairing violence, brutal rapacity and haphazard crime have been thrown on a screen illumined by the torch of civil war. Above everything, the law has been made to look supremely

weak, for in the effort to ferret the facts, the police is represented not by the organized service of the State but by a private detective agency, which boasted unduly of its accomplishment long before the trial began and failed to make good when put to the test. It is to the discredit of popular government that the detection of wholesale crime and widespread conspiracy should necessarily have to be given into the hands of private detective agencies, instead of a properly organized police. After all, government begins with a proper police force; enforce order and the law can take its course; permit violence and it becomes impossible to apply the law. The riot at Wardner, the murders at Telluride, the dynamiting at Cripple Creek would never have occurred if there had been any sort of a police force composed of capable and faithful men. The community at large wants to attend to its business and will not spare enough time for civic duties; the least it can do is to make certain of a police that will check any disorderly interruption to industrial functions and any assault on the life of those who wish to pursue their avocations. If the senators that debauch the State legislatures in order to get elected, and if the congressmen that sell themselves to railroad companies in order to go to Washington, could be retired and their salaries used for the maintenance of a well organized police and detective service, there might be a great improvement in the condition of life that is labeled civilization.

WE ARE ABLE to state that Dr. David T. Day, chief of the division of Mining and Mineral Resources, has resigned. He has had charge of this division in the United States Geological Survey ever since 1884, when he succeeded Albert Williams, who organized the statistical department in 1880. Dr. Day is succeeded by Mr. Edward W. Parker, who has been his chief assistant, with particular attention to the statistics of the coal industry. Mr. Parker was a member of the Anthracite Strike Commission of 1903 and he is not unknown in journalism. Dr. Day, we understand, is to become petroleum expert, remaining on the Survey in this capacity. The retirement of Dr. Day is apparently another step in the reorganization of the statistical department of the Survey. For many years the collection of data was allotted to a number of special agents, such as Charles Kirchhoff, John Birkinbine, Charles G. Yale, George F. Kunz, James M. Swank, and other men identified with particular industries. Of these only Mr. Yale remains in service, a fact pleasant to chronicle, for he was editor of the MINING AND SCIENTIFIC PRESS for 22 years. Instead of engaging experts in the employ of other agencies, the Survey now utilizes its own officers in the collection of statistics. The work has been allotted to a group of younger geologists of marked ability, headed by Mr. Waldemar Lindgren. On another page we quote the statistical report on copper by Mr. L. C. Graton; next week we shall publish similar figures on lead by Mr. J. M. Boutwell. The work is being done well and is deserving of the cordial support of all those engaged in mining.

Personal.

PHILIP L. FOSTER is in Russia.

JOHN B. FARISH is in New York.

C. W. GEDDES, of Goldfield, is here.

R. S. RAINSFORD, of Salt Lake City, is here.

R. V. NORRIS has arrived here from New York.

F. J. H. MERRILL is still at Llanos, in Sonora, Mexico.

C. M. YEOMANS is about to leave El Oro, to go to China.

CHARLES JANIN has returned to San Francisco from Colorado.

LUCIUS J. BOYD, who is operating in Lovelocks, Nevada, is here with his family.

D. E. BIGELOW is chief mechanical engineer for Bewick, Moreing & Co. in Australia.

PHILIP ARGALL sailed from Queenstown for New York on July 17. He is now at Denver.

WILLIAM A. POMEROY is at Palo Alto, California, on a visit from Chinipas, in Chihuahua.

F. B. REECE has returned from El Oro, Mexico. He will visit Butte and the Coeur d'Alene.

FERGUS ALLAN, superintendent of the Mexico mine, at El Oro, is with Philip L. Foster in Russia.

W. L. HOYT has been appointed general manager for the Tasmania Copper Co., at Leigh Creek, South Australia.

ARTHUR W. JENKS has returned to Portland, on the completion of a mine examination in British Columbia.

MILTON MOSS, of Huntsville, Alabama, has been visiting the mining districts of Utah, Nevada, and California.

VICTOR G. HILLS has returned to Denver from an examination of the Spalding district in Custer county, Colorado.

LESTER W. STRAUSS is at Huaraz, in Peru. He has examined mines in the Cerro de Paseo and Morococha districts.

O. H. PACKER, of Oakland, has been examining and surveying the La Joya quicksilver mine in Napa county, California.

FLETCHER HAMILTON has left the Dairy Farm mine to engage in the sale of mining machinery at Torreon, Coahuila, Mexico.

HORACE STEVENS, of 'The Copper Handbook,' has recovered from a serious operation, and is, we are glad to add, in normal health once more.

SIMONDS & BURNS, of New York, have opened a branch office at Haileybury, in the Cobalt district of Ontario, in order to facilitate work in that region.

THOMAS NEILSON, for many years with the Mountain Copper Co., has resigned and has been appointed metallurgist to the Shannon Copper Co., at Clifton, Arizona.

WILLIAM S. MANN, cyanide manager for the Montezuma Mines Co., of Costa Rica, has resigned to accept the management of the Boston & Oaxaca mines at Tlacolulu, in Oaxaca, in Mexico.

WILLIAM P. MILLER has lately returned to San Francisco from the Parral mining district, Chihuahua, Mexico, where he made an examination of the famous Palmilla mine, owned by Pedro Alvarado.

ROBERT H. RICHARDS recently returned to Boston from six weeks in camp in the White Mtn., where he has been engaged in writing the appendix to his book on 'Ore Dressing.' He is now on his way to the West, and expects to be, for a few days, in Flat River, Mo., about July 27; in Great Falls, Mont., about August 5; in Salt Lake City about August 12; in Denver about August 18 or 20.

WILLIAM C. MADGE, who has been in the employ of the American Smelters Securities Co. for several years in the United States and Mexico, as chief engineer in charge of the design and construction of mills, having just completed a mill at Silverton, Colorado, has gone to Salt Lake to open a consulting engineer's office, where he will make a specialty of mining and ore-dressing plant design and construction.

General Mining News.

ARIZONA.

GILA COUNTY.

The Old Dominion is turning out a large amount of copper from the five furnaces running at the smelter. L. D. Ricketts, who is still consulting engineer for this company, and John Langton, mechanical engineer for the Phelps-Dodge company, have been in Globe considering the erection of the new central electric power-plant and new equipment at the mine. The new pumps may be installed in A shaft instead of C shaft. Construction work and mine development are progressing favorably. No. 5 cross-cut on the 14th level is well started and should cut No. 1 sulphide vein within a short time. The double-compartment winze is 75 ft. below the 14th level and is going down as fast as three shifts can sink it. All the important stopes look well and there is a steady increase in ore blocked out.—The new three-compartment shaft, to take the place of the old incline shaft on the Gibson property, has been started by sinking from the surface and raising from two of the levels.—At the Globe Consolidated, good progress is being made in the Mallory shaft, which is now 725 ft. deep. The Gem shaft is 820 ft. deep, still in diorite.—There is still vein-matter showing in the shaft of the Arizona-Colorado mine, which is 650 ft. deep.

GRAHAM COUNTY.

There is a great deal of talk about the consolidation of the Arizona Copper Co. with the Shannon Copper Co., and such a move is not unlikely. J. G. Hopkins has gone to Scotland on behalf of the Arizona Copper Co. to consult with the Shannon shareholders and officers regarding the merger.—The San Juan mine is in the regular shipping list, a number of cars of concentrate having been shipped recently. A large force of miners is employed, and the 30-ton mill is running day and night. They are at present cutting through to the main body of ore from the 360-ft. level, the vein having been first uncovered at the 260-ft. level, where it is said to be 25 ft. wide.

MARICOPA COUNTY.

A company has been organized by Emil Holden to work a placer claim on the Hassayampa river, near Hot Springs. Water will be conducted three miles through an eight-inch pipe.—The mill of the Interior M. & T. Co. on the Big O'Brien property is running. Jas. D. Loughery, the president, and the board of directors live at Pittsburg.—C. C. Harris, of Findlay, Ohio, has been doing some mining in the Big Horn district, and has purchased 10 claims in that country besides having located numerous other claims, and in all has over 100. The ore in that district is gold, silver, and copper, with copper predominating. It has long been known that the district west of the Hassayampa is pretty well mineralized, but it is only of late that people have been doing any prospecting and opening up of claims.—J. C. Dobbins, consulting engineer of the Wallapai Copper Co., whose properties are near Gillette, just south of the Yavapai county line, reports that the company has 53 men at work and that prospects for a new and important copper mining district in that portion of the Bradshaw Mtn. are excellent. The holdings of the company cover 160 acres, upon which a patent was recently secured from the Government. The deepest shaft is down 262 ft., and the operations will be confined to driving and cross-cutting until a new boiler is installed.

MOHAVE COUNTY.

The Arichise Copper M. Co., operating on a group of 12 claims north of Kingman, has made a third payment on the purchase price of the properties. The tunnel is in over 500 ft. and will soon cut the vein on which a shaft was sunk 100 ft., showing copper ore.—Thomas McMahon is working on the old Pixley mine at Layne Springs, and is taking out some ore. The de la Fontaine mill is to be started again. Work is progressing on the Golden Eagle group, in Mineral park, owned by Steve Tyler.—A clean-up from a week's run at the Goldroad mill amounted to about

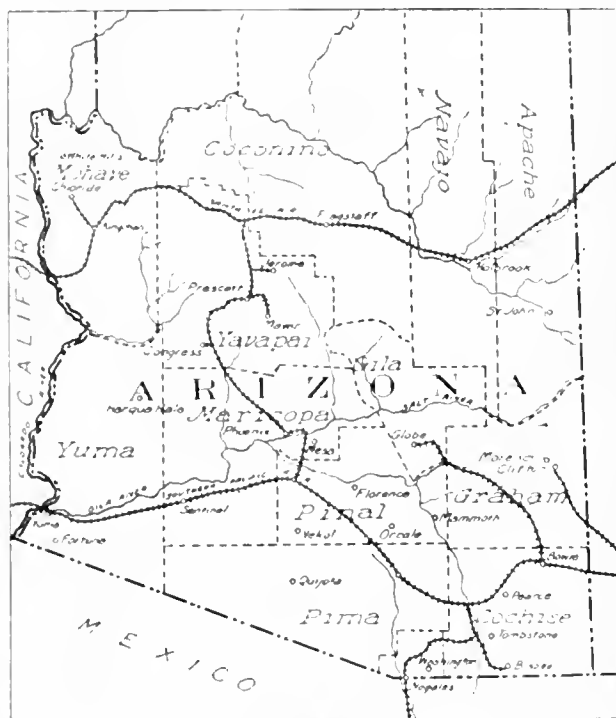

\$30,000 in gold. Good ore is being opened in the lower levels.—A steam boiler is being put in at the Treasure Hill mine, and the shaft will soon be unwatered by pumps.

PIMA COUNTY.

Ferris Fitch, general manager of the Weldon Copper Co., has completed negotiations for a 30-stamp mill. The company has a force of more than 50 men employed at its mines on the Weldon properties.—There are 5,000 tons of ore at the Omega property, in the Helvetia district, ready for shipment, but it is difficult to get teams to haul to Vail station. There is said to be a good demand for Omega ore at Globe for fluxing.

PINAL COUNTY.

The J. Baldwin syndicate, of which J. P. Harrington is the president, has taken over the Sultana mine. The purchase price was \$90,000, and they are shipping ore that runs up to 20% copper. They are preparing to sink a vertical shaft and to build an aerial tram to a concentrating plant, and from that down to the railroad. There are several thousand tons of low-grade ore on the Sultana dump which it will not pay to ship to the smelter that will be concentrated on the ground when the plant is put in. The Sultana

Map of Arizona.

claims extend over about 300 acres and the company is figuring on buying 600 more acres.—New York capitalists are negotiating for the purchase of a group of claims at Superior, owned by Mesa prospectors.

YAVAPAI COUNTY.

(Special Correspondence).—The Commercial Mining Co., operating in the vicinity of the Mt. Tritle property, in Maxton district, is driving the Senator tunnel, which, if it is driven on through the mountains, will be over two miles in length. It is now in about one mile, and work is being pushed. The tunnel is a fine piece of work, and is being driven to enable the company to develop and mine the ores from several veins that are known to exist on the property. Aside from developing this property, the Senator tunnel will be of benefit to the other mines in the district.—The Storm Cloud company is pushing development work upon the same system of veins that show on the Commercial ground, and it is shipping ore regularly to the Humboldt smelter. The activity of the Commercial company will probably mean a smelter for the Maxton district, and a railroad. The Storm Cloud company and the Mt. Union company may have reduction plants of their own. There is plenty of water in all parts of this belt.—The Mt. Tritle Copper Co. has one of the best properties in the district. Its ground is on the same veins that are being opened by the Senator tunnel, and the Mt. Tritle vein may

be an extension of either the Senator No. 1 or 2 vein. The ore is similar. The Mt. Tritle is driving a tunnel 600 ft. above the Senator tunnel level. In the veins sulphides are found at the surface. The ore contains pyrite, chalcopyrite, free gold, and silver sulphides, and the gangue is quartz, making an ore that could be handled by concentration.

Prescott, Aug. 1.

(Special Correspondence).—Development work is progressing on the Little Daisy, owned by J. J. Fisher.—The Jerome-Verde Mining Co., under the management of C. H. Putnam, is making preparations for the development of that property. A wagon-road is being built, and the force of men will be increased. This company has plenty of money for development purposes, and no stock is for sale. The showing on this property is excellent, and development will be watched with interest.—The work of unwatering the 1888 shaft of the Hull Copper Co. is progressing, and sinking will be resumed in a short time.

Jerome, July 17.

The United Verde smelter at Jerome has been temporarily closed while the overhead crane track was being repaired, not on account of a cave-in from the surface, as was reported.

Splendid headway has been made during the past four months in the lower tunnel of the United Verde at Jerome. In 117 days the tunnel was advanced 1,058 ft., being an average of about nine feet per day, although hand-drilling was done for the first 400 ft. At present two machines are being run for two 8-hr. shifts, with three shifts of muckers working. The tramming is done by mules. The tunnel will be 7,000 ft. long and will tap the mine at a depth of 1,000 ft. It is 7 ft. high, 9 ft. wide at the bottom, and 7 ft. at the top, in the clear, and is heavily timbered throughout. The portal is on Bitter creek, a mile below Jerome.

CALIFORNIA.

EL DORADO COUNTY.

A deal is pending for the sale of the Ada mine by E. F. Porter.—The Standard Unit mine in Coloma canyon has resumed operations with Sam Beers as manager.—The Wolff property is being opened by Chris Raabe and a mill may be built.—The stamp-mill at the Hanson mine is being repaired and will be started.—The new 10-stamp mill at the Vivian mine is nearly completed.

A good body of quartz has been struck in the Isabel mine, owned by M. P. Bennett. The property was formerly called the Blue Lead and was a surface producer of gold.—W. K. Reed is making a survey from the Arterburn group of claims to the canal of the Leon Lake W. & P. Co., with a view to bringing water to the properties, which lie at the serpentine contact, about three miles south of the Three Queens, Josephine, and Trench mines.—C. D. Wilkinson and A. W. Flint are in charge of the work on the Alpine mine.

NEVADA COUNTY.

The water has all been pumped out of the Morning Star mine at Badger hill. Oscar F. Greeley has reported on the property.—The Norambogua tunnel has been cleaned for its entire length, and it is ready for the rails which should arrive soon. Work on the new air shaft is progressing rapidly.—The Cold Spring Co. expects to have the tunnel of the Buckeye quartz mine into the shaft at the 125-ft. point, within a short time. After the connection with the shaft is made, the tunnel will be continued on the vein for 2,000 ft. into the Cold Springs ground, in order to prove it thoroughly.—The water has been lowered to the 300-ft. level in the Banner mine, and the workings will be dry within a month. Bulkheads will be built on the 300 and 600-ft. levels to hold back the water.—A good copper vein has been struck in the South Yuba property of the Omaha-California company, of which Matthew Daugherty is the superintendent.

COLORADO.

SAN JUAN COUNTY.

Three carloads of concentrate are shipped daily from the Gold Prince mill at Animas Forks to the Durango smelter.—A force of men is working in the Domingo tunnel at

Eureka, which has been idle for eight months. Samuel Davis is the local manager.—A. A. Beard has taken a lease and bond on the South Democrat mine in the Animas Forks district. This is an old property that has produced considerable ore. The old mill will be remodeled and started.—Operations have been started by the Peerless San Juan M. & M. Co. on the Dr. Beaton properties in Minnie gulch. A new electric compressor has been set up, and three machine drills are working. Ben Dunstan is the foreman. Shipments will start at once to the Durango smelter, and a mill will be built this fall.—The Ross smelter had to close down for a week on account of a wash-out on the Silverton Northern railroad, but it is running again.—J. N. Kloster has resumed work on his Gold Bug claims in Stony pass. One tunnel is 75 ft. long, and a second one is 350 ft. long. He will ship about four carloads per month. The new Detroit & Colorado tramline will soon be finished, whereupon shipments will start.—A force is working on the property of the Gold Mines & Power Co., at the head of Elk creek.—The shaft of the Dakota Mining Co. in Boulder gulch is down 100 ft., and a contract will be let for another 100 ft. John Martin is the manager.—The Astor Mining Co. has resumed work on its properties at the mouth of Picayune gulch. They are working on the Toltec vein, and have been developing the property for years.—Eastern capitalists are negotiating for the purchase of the Parker, Excelsior, Protection, Avalanche, Copper Falls, Republican, and several other claims in Boulder canyon.—The upper tunnel of the Nugget Con. M. Co., operating in Maggie gulch, is in 250 ft., while the lower tunnel is 100 ft. long. Good ore has been struck, which will be shipped as soon as the wagon-road is completed.—An 800-ft. tunnel has been driven by the Bullion Bar M. Co. in Maggie gulch. C. P. Campbell, of Colorado Springs, is the president, and T. E. Major the treasurer.—All of the mines at Red Mtn., in which George Crawford is interested, will be started up again. They are the Red Mtn. R. M. & S. Co., the Blue Bell M. Co., and the Gold Lion M. Co. The first property is drained by the Joker tunnel, which has been driven to within 600 ft. of the Genesee shaft, and will be run farther to cut it 800 ft. below the Genesee tunnel.

IDAHO.

SHOSHONE COUNTY.

Machinery is on the ground at the Charles Dickens mine near Osburn, and with its installation the capacity of the mill will be doubled. It will be set up at once, and the work is expected to be completed soon. The capacity of the mill is now 75 tons per day. Two jigs and one table will be added to the equipment. The property is in excellent condition, with bright prospects. Samples of the ore run well, and do not show much zinc. Six samples of concentrate averaged nearly 70% lead, and show half an ounce of silver to each per cent of lead.—The concentrator at the Stewart mine in Government gulch, near Wardner, has been completed, and will have a capacity of 150 tons daily. The concentrator is near the mouth of the Silver King tunnel, and it is expected to handle the ores from the Heinze properties, including the Silver King, Stewart, and Crown Point. The Senator Stewart already has several thousand tons of ore on the dump ready for the concentrator. A tunnel is being run on the Silver King east toward the Senator Stewart, and will do the prospect work for both mines below the depth of the main tunnel on the last named.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence).—For the week ending July 27, the Goldfield properties shipped 3,143 tons of ore valued at \$345,250. Of this amount 480 tons, valued at \$48,000, was shipped to the smelter by the Mohawk; 475 tons, valued at \$23,750, was treated at the Combination mill; and 2,188 tons of ore received from the following mines by the Nevada Goldfield Reduction Works: Mohawk Florence, 161 tons; Mohawk Jumbo, 570; Little Florence, 80; Mohawk Combination, 484; Sheets-Fish dump, 23; Red Top, 247; Hayes & Monnette dump, 221; McNaughton lease, 95; Mohawk, 120; Combination Fraction, 29; Higginson lease, 98; Codd

lease, 33; Sandstorm, 21 tons. Total, 2,188 tons, valued at \$275,500.—The Frances Mohawk lease on the Wedge has struck a shoot of ore at a depth of 360 ft. The vein is three feet wide and runs well. The shaft will be sunk an additional 100 ft. and a station cut.—The Codd lease on the St. Ives has ore on the 100-ft. level. The shaft is being put down 400 ft.—A good body of ore has been struck near the 300 level in the shaft on the Great Bend No. 2, at Diamondfield.—A vein, carrying low-grade ore, has been encountered in the Happy Hunch mine, eight miles east of this city. At the Queen of Sheba, in the same district, a 100-ft. shaft is being sunk. Some ore has been found in the Red Hills, and development is steadily progressing.

Goldfield, July 27.

HUMBOLDT COUNTY.

(Special Correspondence).—Two shafts and two cross-cut tunnels are being driven on the Brown Palace, and two shafts are going down on the Dreamland, where the vein is stripped for 200 ft.—The Rosebud-Rattler is driving an east drift from the tunnel with the expectation of striking the ore-shoot exposed on the surface.—A vein has been cut in the 425-ft. tunnel in the Golden Anchor, and is being driven on.—A shaft is being sunk on the Golden Triangle. A vein carrying silver is being developed in the Durango Girl.—The shaft on the Warner-Stewart is down 75 ft. A small vein is being developed.—A 12-in. vein carrying silver, has been struck in the White Cat.—The shaft in the Five of Diamonds has exposed a vein.—The Seven Troughs Pinte M. Co. is developing its lease on the Boilermaker, and the shaft is down 50 ft. The company has secured a new lease on the Seven Troughs King and will commence operations at once. John B. Newman has been appointed general superintendent of the Seven Troughs Pinte.—The Gold Quartz company is sinking a shaft on its most promising claim, and has leased parts of its holdings.—A syndicate of Butte capitalists has been organized to take over the group of claims owned by the Cusick syndicate near Tenabo.

Rosebud, July 25.

LYON COUNTY.

(Special Correspondence).—The Ramsey-Comstock mine is to ship some ore to the Utah smelters, the first consignment to be sent by August 1. The ore occurs in a porphyry dike that is 70 ft. wide and has been driven on for several hundred feet. Driving on the levels is progressing steadily and a mill is to be erected.—Another property having some ore is the Walkover mine, that lies about two-thirds of a mile west of the Ramsey-Comstock, and has a dike that contains surface ores. A small vein of ore was encountered in a prospecting tunnel at a depth of 25 ft. from surface.—On the east extension of the Ramsey-Comstock the Ramsey-Ophir M. Co. has uncovered a tunnel 60 ft. from the surface. They plan to sink a 500-ft. shaft in the hanging wall.—The Ramsey-Consolidated M. Co. is cross-cutting at the 300-ft. level on Dago No. 2 claim. The workings are below water-level, in the sulphide zone, and will be over 500 ft. from the apex of the dike when that point in the cross-cut is reached. On the adjoining Dago No. 1 claim, a prospecting tunnel is being driven.—The Ramsey-Bonanza company has uncovered some ore with a shaft and cross-cuts, at a depth of 100 ft. from surface, and has ordered some machinery and equipment. Two veins are exposed.

Ramsey, July 22.

NYE COUNTY.

(Special Correspondence).—The development of the properties of Manhattan is proceeding slowly. Some milling ore has been found in the mines on Mustang hill, at depth, and some exploration has been carried on below the water-level, or about 250 ft. down.—A little tellurium ore has been encountered in the Thanksgiving mine. Ore was first encountered at 210 ft. and was sunk upon to the 236-ft. level, when a steam-hoist was installed, sinking resumed, and at a depth of 252 ft. a little ore is still showing in the shaft, which is in highly silicified sedimentaries.—The Manhattan Ore R. & R. Co. is building a small mill on Mustang hill. It was designed by F. L. Bosqui, and is being built under his supervision. The treatment determined upon is to stamp the ore, amalgamate, fine grind in tube-mill, treat with secondary amalgamation, and then agitate and

filter the product in the Butters patent vacuum filter. The stamps are erected on the masonry mortar blocks, the tube-mill is in place, excavation is about completed, masonry retaining walls are about done, and all material to complete the plant is in transit, and it is hoped to complete the plant in the early fall. The initial capacity will be 60 tons per day.

Manhattan, July 23.

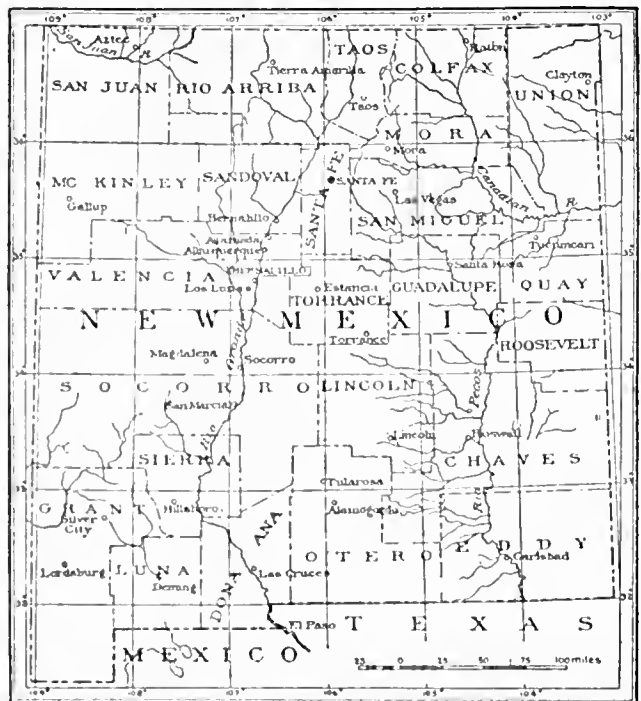

NEW MEXICO.

GRANT COUNTY.

The Comanche M. & M. Co. is erecting a new 300-ton furnace at its smelter. The engine and blower are in place and the machine-shops are in operation. The furnace was made by the El Paso Smelter Supply Co. The Comanche company's concentrator is treating about 100 tons of ore per day, from the Pinos Altos mines, and the capacity of the plant will soon be doubled.

SIERRA COUNTY.

Some work is going on in the Hillsboro district. The Sierra Consolidated M. Co. is completing a steel-frame 100-ton stamp-mill, and 50 men are employed at the mine.—

Map of New Mexico

The Ready Pay Reduction Co. is putting in a Huntington mill to treat its low-grade ore.—The Empire Gold M. Co., which has produced for 20 years, has a 20-ton mill steadily at work, and ships high-grade ore to the El Paso smelter, employing 35 men at the mine.—The Hillsboro Consolidated M. Co. is cleaning out its shaft and tunnels and will produce ore again.

TAOS COUNTY.

In the Burro Mountain district, the Copper Gulf Development Co. has installed new pumps in the Virginia and Copper Gulf shafts, which are down to water-level, and sinking will be resumed.—The Ocala Copper Co. has resumed work on its property, under the direction of R. P. Thompson. The shaft is down 185 ft. and shows low-grade carbonate ore.—The Burro Mountain Copper Co. has opened a body of ore 400 ft. long running 4% copper. It has also sunk a shaft on the Boston claim, which is bottomed in ore.—The Tyrone Development Co.'s shafts No. 1 and 2 are still in ore at a depth of over 300 ft.—The Santa Fe railroad will build a spur to this district.

TRES PIEDRAS COUNTY.

(Special Correspondence).—The 500-ton smelter of the Southwest S. & R. Co. is almost completed, and the furnaces will soon blow in. The tramway from the Lucky Flat district to the ore-bins is nearly completed.—The First National is driving the tunnel on the Ruby, and is preparing to install a 100-ton placer plant.—The shaft on the

Cuprite is down 150 ft., and several shipments have recently been made.—The Turquoise Copper, and Hershberger properties are shipping ore to the El Paso smelter.—The Southwest company is installing a steam plant and drills at the By-Chance, and will thoroughly develop the mine. The ore carries gold and copper.—An eight-foot vein, carrying gold and copper, has been struck in the 50-ft. shaft in the Shamrock.—The Electric M. Co. is installing a placer plant. The pipe-line from the Sacramento river is completed, and the 25,000,000-gal. reservoir is nearly filled. Water is also being obtained from the Valley shaft of the Lucky and other mines.

Orogrande, July 23.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The Golden Placer M. & M. Co. has purchased the Kicking Horse placer ground of 40 acres, in Blacktail gulch, from George Johnson and Chris Godfrey. The property has been a producer for years.—Stockholders in the Victoria Mining Co. have recently visited the property in the Ragged Top country below Iron creek. Good ore is being developed. A good deal of new machinery has been installed at the Keystone, including boilers and an engine, Wilfley tables, and an air-compressor. A large force of men is at work at the mines, advancing 11 shafts and five tunnels.—The charter of the Segregated Iron Hill M. Co. has expired by limitation, so the surviving directors become trustees. A new corporation has been formed to take over the old holdings, and O. P. T. Grantz is president and D. A. McPherson treasurer.—A good vertical shoot of ore has been discovered in the American Eagle property. A new 200-ton cyanide mill is being built.—The Lundberg-Dorr-Wilson mill has started again, after having been idle since the strike last winter, and is handling 90 tons per day.—An English syndicate has taken a 60-day option on the Two Bit property, from S. R. Smith and A. J. White.—A strike of good ore has been made on the ground of the Echo Mining Co., in the Garden City district, at the 300-ft. point in the tunnel that is being run in a southwest direction. A. J. Simmons is the manager and the stock is owned principally in New Hampshire.—The Columbus Con. M. Co. is offering unsecured creditors stock of the company for their claims, on the basis of 25c. per share. The office of the company is in Chicago, Roswell A. Breed is president, and Arthur J. Kirkwood treasurer.—The Branch Mint Co., at Galena, will soon start its 120-stamp mill and treat 500 tons of ore per day from the Hoodoo shaft. A railroad is being built from the mine to the mill and a large force is employed.—The Imperial company has acquired the ground of the Dakota Mining Co. in the Bald Mtn. country.—The North Homestake Co. is hauling coal to its property from Blacktail gulch, although it has not been announced when they will start the mill. The diamond-drill work continues from the levels at the bottom of the 225-ft. shaft.—The Lady of the Hills ground, on the antimony belt at Silver City, has been bonded to New York parties. The 5-stamp mill of the Grand View M. Co. on Rapid creek is working steadily, after a short shut-down.—The directors of the Success G. M. Co. have decided to build a mill on their property near Roubaix.

The water in the Homestake mine is below the 600-ft. level, and stoping has started on the 500-ft. level, over 1,000 men being at work and the mills running to their full capacity. When the water is lowered to the 800-ft. level the big pumps at that point will be started.—Work at the Puritan Mining Co.'s property, at the head of Strawberry gulch, near Deadwood, will soon be resumed, as the necessary financial backing has been secured. There is a 20-stamp mill on the property, with a cyaniding equipment, which was built three years ago. Vanners will be put in to work the Wilfley tailing over again.

PENNINGTON COUNTY.

The Standard smelter at Rapid City may be run again if C. H. Fulton succeeds in interesting Eastern capital sufficient to develop some of the old properties near Galena. The plant was forced to close down because of the lack of ore.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—It is expected that the Winnipeg adit will be through to the old workings by August 6. It is advancing nine feet per day.—The adit of the Blue Bell-Belcher has tapped a vein of oxidized quartz ore which shows stains of copper, but has not yet touched the iron sulphide vein.—Preparations are being made to work the Oregon & Washington mine in the San Poil district.—The adit on the Vesuvius mine, near Keller, has tapped and drained the shaft on the vein, and some high-grade copper ore has been uncovered.—The Copperopolis M. & L. Co. has sent mining supplies to the Last Chance mine, in the San Poil district, and plans development on a larger scale than usual.—The Gold Seal M. Co. is erecting a boarding house at the Gold Seal mine, on Bridge creek. Ample capital has been raised for development. William Gallup is in charge at the mine.—The Spokane and St. Lawrence claims of Camp Gilbert, in the Twisp district, have been bonded to an Eastern company, organized with a capital of \$7,000,000, and a project is on foot to build 100 miles of electric railway, in conjunction with a smelter of 1,000 tons per day capacity. This company proposes to buy a number of claims to keep the smelter operating to its full capacity. It is stated that the intention is to construct the railway from Twisp to tidewater on Puget Sound, with a branch from Potero, up the Twisp river, to Robinson. A custom rate for freight and treatment of \$3.50 per ton is possible. The Copper World Extension M. Co. is planning improvements to get its ore down from the summit of Palmer Mtn., and ship to the smelters. The Eastern stockholders are well pleased with the condition of the mine.—A new gasoline hoist at the Ben Harrison mine, at Chesaw, is working satisfactorily. At a recent stockholders' annual meeting Basil Doerhoefer, George Holzbog, Wm. A. Roberson, C. J. Weibel, John Sidler, George Edgington, and James P. Blaine were elected trustees for the ensuing year.—The machinery for the Molson Mining Co.'s new mill has arrived and is being installed. The trustees and executive officers elected July 8 were D. W. Dart, president, and general manager; W. B. Van Wormer, vice-president; C. W. Smith, secretary; M. A. Smalley, treasurer, and H. N. Michel, M. E. Schreck, and H. F. Beery, trustees.—The Grant Consolidated Copper Co. has concluded to drive an adit 1,500 ft. through Copper Mtn., to develop three veins at depths varying from 300 to 800 ft. Ore shipped from the Grant has brought smelter returns approximating 6% copper, and \$4 in gold and silver per ton.—In the case of the Mountain Sheep M. Co. v. the Ruby Mining Co., in which the complainant alleged that the defendant had taken ore from its ground, a decision was rendered by Judge E. R. Steiner in the Superior Court in favor of the defendant.

Republic, July 30.

George Belt, resident agent for the plaintiff, recently appeared before the State Supreme Court in an effort to compel the Secretary of State to file the articles of incorporation of the Amalgamated Republic Mines Co. The company, organized under the laws of Arizona, has a working bond on practically all the mines in the Republic district, north of Spokane, to treat the ores by a new process. The Secretary of State has refused to accept the articles of incorporation on the ground that they permit the company to deal in real estate. The company has appealed to the Supreme Court for a writ of mandamus to compel him to permit the filing of the articles in their present form. The matter is now pending before the Supreme Court until the attorneys for the State have filed a brief in answer to the company's arguments.—Changes have been made in the management of the Belcher company, which owns the Belcher properties near Republic camp, north of Spokane, where development work is being done by several concerns. J. H. Harper has resigned as superintendent. The property, which has been closed since the beginning of the year, will open in August, when the company will begin shipping. The new directors are: J. A. Anderson, of Rosalia; Judge Chadwick, of Colfax; C. H. McNaughton, of Winniepeg; Hugh Armstrong, of Portage, La Prairie

Mark Merrit and J. E. Kennedy, of Rosalia, and R. N. Murphy, of Detroit. They will meet in Spokane next month to elect officers.

STEVENS COUNTY.

(Special Correspondence).—The British Columbia Copper Co. is shipping approximately 100 tons of ore per day from the Napoleon mine, which assays about \$4 per ton in gold, silver, and copper, 20% sulphur, and from 40 to 45% iron. T. L. Greenough & Bros. have taken a bond for a controlling interest in the Butte & Chief mine, in Pierre Lake district. Active work on the property will be done with two shifts under Miles McNally, the owner.

Republic, July 30.

BRITISH COLUMBIA.

Shipments from Rossland for the week ending July 20 were below the average, due to a lay-off on Miners' Union day, and the burning of a bridge on the Great Northern railroad. The Centre Star shipped 3,600 tons; Le Roi, 2,100; Le Roi No. 2, 420; and the White Bear, 175 tons of ore. Total, 6,295 tons.—At the Centre Star, the development work on the Idaho continues and indications seem to show that this may be one of the most valuable properties of the Consolidated company. The drift toward the Idaho is in 220 ft. The Iron Mask furnishes good shipping ore.

Map of Part of British Columbia.

—At Le Roi, the development in the territory west of the Josie dike continues and ore-shoots are being developed on four levels there. Drilling is being done east and west on the lowest level of the Spitzee.—In the California tunnel of the California-Giant a station is being cut preparatory to starting a winze, and on the lower level of the Giant driving is in progress.

The Trail smelter received during the week 5,177 tons of ore. In addition to shipments from Rossland the following contributed to this tonnage: Snowshoe, Phoenix, 411 tons; Victoria, Nelson, 149; St. Eugene, Moyie, 385; North Star, East Kootenay, 185; Planet, 187; Arlington, Erie, 25; and Sunset, 21 tons of ore.—At Le Roi smelter at Northport 2,100 tons of ore were received. Three furnaces are handling 600 tons per day.

The Boundary shipments for the week were: To Granby smelter from Granby mines, 4,489 tons. To B. C. Copper Co. smelter from Mother Lode, 5,246; from Snowshoe, 2,930; from Emma, 162; from Oro Denoro, 1,907 tons. To Dominion Copper Co.'s smelter from Brooklyn, 1,419 tons; from Rawhide, 2,441; from Sunset, 945; from Mountain Rose, 140 tons. To Trail smelter from Snowshoe, 1,030 tons. Total shipments for week, 36,713 tons, and for year to date, 610,464 tons. During the week Boundary smelters treated ore as follows: Granby smelter, 19,691 tons; B. C. Copper Co.'s

smelter, 10,430; Dominion Copper Co.'s smelter, 4,949 tons. Total district treatment for week, 35,040 tons, and for the year to date, 599,228 tons.

The shipments of ore and receipts of smelters for the week ending July 20 were: From the Boundary district, 36,154 tons; Rossland, 5,546; and districts east of the Columbia river, 2,772 tons of ore. The smelter receipts were: Grand Forks, 20,489 tons; Greenwood, 10,083; Boundary Falls, 4,949; Trail, 5,117; Nelson, 110; Northport, 1,818; and Marysville, 600 tons of ore. Total for the week, 43,166, and for the year to date, 800,725 tons of ore.

There is still a shortage of miners in the Boundary region, but more men are coming in daily.—The Granby Consolidated company is planning to increase its smelter capacity from 3,000 to 4,000 tons per day. The company is beginning to exploit the claims recently bonded from the Amalgamated Copper Co. of Phoenix, which are superintended by Charles Biesel.—The British Columbia Copper Co., owning the Mother Lode group of mines and the smelter at Greenwood, has declared a dividend of 25c. per share. It is thought that the company will now pay regular quarterly dividends amounting to \$1 per share per year, as the affairs of the company are in a prosperous condition, and the equipment and mine are in the best of shape.—Diamond drilling is being continued at the Elkhorn mine. Contracts have been made for Coleman coke by the International Coal & Coke Co., with the B. C. Copper Co. and the Dominion Copper Co.—The survey has started on the five-mile aerial tramway from the Dominion Copper Co.'s Phoenix mines to the Boundary Falls smelter.—It is rumored that instructions have been received from England to unwater the Carmi mine.—The Granby company has let a contract for a 200-ft. raise from the face of the Curlew tunnel. The new crusher for the company's Gold Drop mine has been shipped from Quebec, and work has started on grading for the crusher and ore-bins. The present ore-bin will be moved to the mouth of the Curlew-Gold Drop tunnel.—The Phoenix syndicate that has a bond on the Le Roi-McKinney mine, west of Rock creek, has proved the existence of a large orebody, after two months' work.—At Slovan, shipments of silver-lead ore will probably be curtailed for some time, as the Nelson smelter has notified the companies that no ore will be accepted, which leaves only the Trail smelter, of small capacity, to handle the output.—In East Kootenay, a good tonnage of silver-lead ore is produced, the principal shipping mines being the St. Eugene at Moyie, and the Sullivan and North Star at Kimberley. The Stenwinder will probably be a shipper for another year. The lessees who unwatered the Cariboo last January, are working 18 men, and are stoping and operating the mill.—Control of the Crow's Nest Coal Co., operating in the Boundary country, at Michel, Coal Creek, and Morrissey, has been acquired by James J. Hill, president of the Great Northern Railway Company, and Jay P. Graves of Spokane, president of the Inland Empire Electric Railway system, the latter securing 8,000 shares, which with 45% of the stock owned by Hill, give the Great Northern control. This will give the railroads and the Granby smelter a supply of coke and steam coal. This company has mined 720,449 tons of coal during the past year, and has produced 189,385 tons of coke.

NICARAGUA.

The following are some of the properties and their equipments in the Pis-Pis district: The Siempre Viva has a 20-stamp mill. S. D. Spellman is president and Samuel Weil the treasurer. The Lone Star, of which Norman McInnis is president, has 20 stamps. The Concordia, owned by N. J. Martin, is dropping 10 stamps, as is also the Constancia of the Nicaragua Gold M. Co. The Neptune has five stamps and is owned by Joseph Lapierre. The Bonanza, Mars, Minnesota, San Antonio, and Santa Rita mills are all equipped with Huntingtons.—In the Prinzapulea district, the La Luz y Los Angeles company, of which Thomas B. Riter is president and W. M. Rees treasurer, is operating, and the Monte de Oro property is equipped with a Huntington mill.—The Nicaragua property, in the Great River district, is owned by William J. English.—In the Sigüia district the Topaz property is equipped with 20 stamps. W. H. Brown is the president and manager.

Special Correspondence.

London.

Indian Mining.—Good News for Deep Workings.—The Great Boulder Mine.—A Fine Record.—Dividends From Camp Bird and El Oro.—News From Mexican Mines.

The Mysore Gold Mining Co. has issued interesting information to the shareholders. The circular alludes to the developments at Edgar's shaft, as advised in the following cable messages from the mines: "Have met with quartz Edgar's shaft at a depth of 2,370 ft. The quartz is 4 ft. wide; assay value, 17 dwt. per ton. Intersected east part of lode Edgar's shaft at a depth of 2,405 ft.; 3 ft. wide; assay value, 1 oz. 12 dwt. per ton." Edgar's shaft, which is vertical and measures 18 ft. diam. inside the brickwork, was commenced some years ago with the object of striking the Champion lode at an estimated depth of 2,500 ft. from the surface. The lode is in two parts, designated the 'western' and 'eastern.' The western portion, as seen above, was encountered at a depth of 2,370 ft. and the eastern at 2,405 ft. In confirming the first cablegram, the acting superintendent writes: "The lode averages 4 ft. of solid quartz, a few of the samples from which gave by assay over an ounce of gold per ton; the average of 20 assays, however, was 17 dwt., as stated in the cable message." The latest message advises that the eastern portion was 3 ft. wide, worth 1 oz. 12 dwt. per ton. The vertical depth at which the eastern part has been cut is some 160 ft. below the horizon of the deepest level at Ribblesdale's shaft, namely, the 3,526 ft., measured upon the inclination of the lode, and upon Edgar's shaft reaching 2,500 ft., this section of the property will be three levels, or 300 ft., deeper than the 3,526 at Ribblesdale's. The directors point out that the importance of these discoveries will be obvious, proving, as they do, the persistence of the Champion lode in depth with great width and value. It is proposed to continue the sinking of Edgar's shaft vertically to a depth of 2,550 ft., and then to carry it down approximately on the dip of the vein. The equipment of the shaft will shortly be undertaken, during which communication will be effected with some of the deep levels from Ribblesdale's and Tennant's, and on the completion of the equipment the haulage of quartz through Edgar's will at once commence. This shaft will become in the future the principal hauling centre and prove of immense benefit to the company by reason of the facilities which it will afford for the rapid and economical transmission of ore to the surface and the conveyance of the men to and from the scene of operations. The directors add that the deepest levels at Ribblesdale's, Tennant's, and McTaggart's continue in rich ore, and they anticipate when the time shall have arrived for them to issue their next annual report to the shareholders, they will be in a position to state that the year's operations have again been of a most satisfactory character and resulted in a substantial addition to the large reserve of payable ore already existing at December 31 last.

Another Indian gold mine—the Nundydroog—is showing signs of improvement, an important point being the winze below the 2,150-ft. level north of Kennedy's shaft (127 ft. north of the shaft), where the quartz is reported to be 2 ft. wide, assaying 2 oz. per ton. Another pleasing feature is the excellent appearance of the developments in the 1,900-ft. south rise (435 ft. from the shaft), on the western lode, where the quartz is reported to be 2½ ft. wide, worth 2 oz. per ton. In the 230 ft. south from south cross-cut east (619 ft. from the North shaft),

the side lode is still opening up well. The drift has been continued for 52 ft., and the latest advice states that the quartz is 1 ft. wide, assaying 1½ oz. The drift has revealed high-grade ore throughout. The side drift from the 1,900 ft. north (180 ft. from the Richards shaft) shows quartz 1 ft. 13 in. wide worth 2 oz. per ton.

At the thirteenth annual general meeting of the Great Boulder Proprietary Gold Mines, Ltd., the chairman, George P. Doolette, proudly claimed that the Great Boulder remains the premier mine of Western Australia and one of the greatest gold mines of the world. He reminded the stockholders that in a little over 12 years it has produced over £5,250,000 sterling in gold, and has paid over £2,500,000 in dividends, and he said he could not see why during the next 12 years it should not maintain that rate of production and percentage of profit. During the year under review they had treated 149,940 tons of ore in addition to 28,597 tons of tailing for a money value of £554,797, as against 132,052 tons of ore and 31,842 tons of tailing, which gave £545,087 sterling for the previous year, and, notwithstanding this large output they have added to their ore reserves during the year nearly 100,000 tons; so that the ore developed during the year has been, in round figures, 250,000 tons, the average value being well maintained. The chairman thought it would be interesting reading to the shareholders, as they go through the reports, to see the splendid developments that have taken place at the different levels below the 1,300 ft., where the tonnage has been enormously increased and the average values more than maintained. The upper levels show a somewhat decreased quantity of ore, but that is owing to the extensive stoping that has taken place in these levels to keep pace with the requirements of the mill. Mr. Doolette said that the previous year had been a record year, but this year they had beaten the record, in the tonnage treated, in reduction of costs, in the profit made, and in the ore developed—and although the large additions to the ore reserves down to the 1,900-ft. level have reduced the average value of the ore by about 1¼ dwt., yet the gross money-value is increased and is over £2,000,000 sterling, that of the past year being about £1,800,000; and this estimate is a conservative one, and deals only with ore blocked out on three sides down to the 1,900-ft. level. Referring to the filters, the chairman considered they reflected the greatest credit on the ingenuity of their engineer and assistant manager, Mr. Ridgway. The costs were not yet available; but it seems certain that the cost of filtering by means of the Ridgway filter will be less than half that by the ordinary filter-press, and, on a basis of 500 tons per day, a saving of £4,000 or £5,000 per year may be expected. With regard to the outlook for mining in Western Australia, Mr. Doolette remarked incidentally that during his recent visit there he had traveled over 5,000 miles in going to the chief mining centres. He had seen the principal mines from Ravenshorpe in the extreme south to Black Range and Nannine in the north and northwest, and the strong impression left on his mind was that there are scores of veins throughout these various districts that fully warrant active prospecting and development.

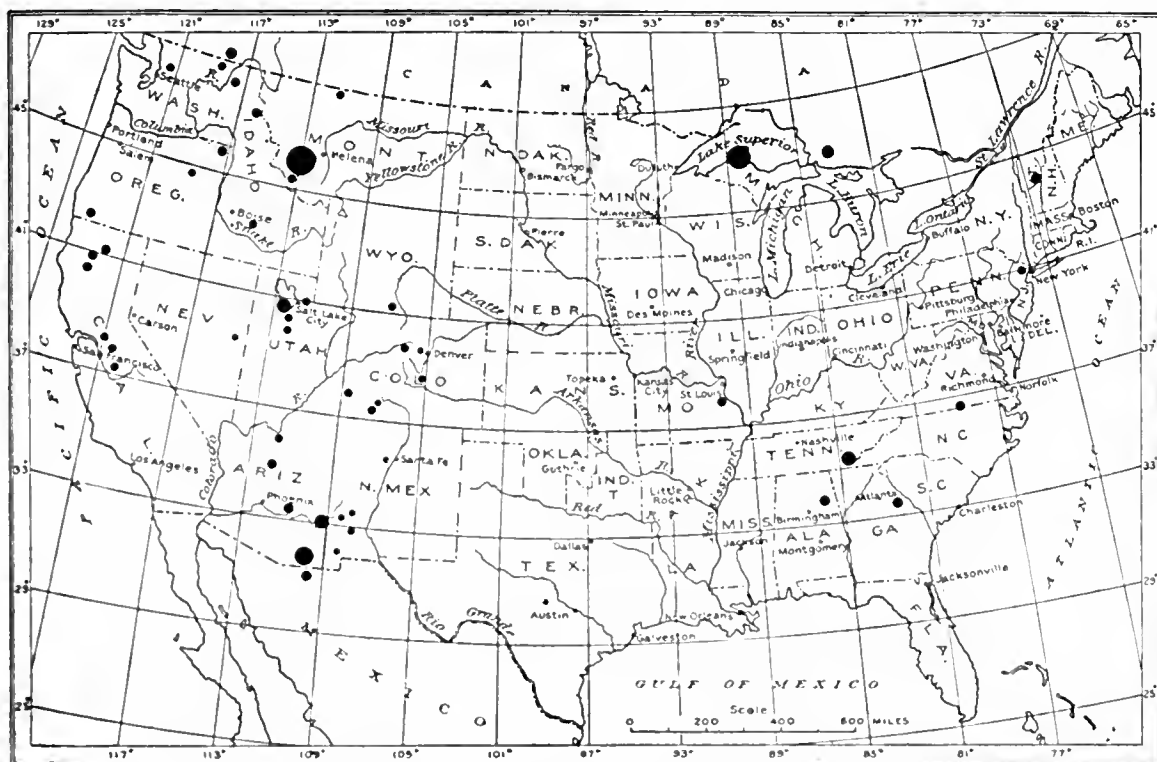

With the payment of the interim dividend of a shilling per share recently declared by the directors of the Camp Bird, the whole of the issued capital of £820,000 will have been returned. This is not a bad record for a company which, although registered on September 8, 1900, did not enter into possession of the property until May 12, 1902.

El Oro has just paid a dividend of 1s. 6d. per share. The directors have issued a circular giving information with regard to the important development which has

been carried out on the 1,000-ft. level during the past half year. The announcement of the June return at the mine is as follows: The No. 1. and No. 2 mills both ran 29 days, and together crushed 22,096 tons of ore, producing \$202,793; less working expenses (\$95,051), and the development expenses (\$12,508), \$107,559, or \$4.87 per ton; profit from the railway for the month, \$12,688; total, \$107,922. The sum of \$2,702 was expended during the month on permanent improvements.

Dolores results for June are not yet to hand, but it is rumored that the mine is again opening up well and that the net profit for the month will be little short of \$50,000, and would have been more but for breakages in the mill

business is shown by the results at Cananea, which have drawn, in addition to W. C. Greene, the attention of the largest copper interests in the world, until there are now operating in Cananea the Phelps-Dodge, or the Copper Queen people; Thos. F. Cole, and John D. Ryan and associates, or the Amalgamated Copper Co.; Thompson and Watson, with the Guggenheims in close sympathy; Chas. M. Schwab and associates of Pittsburgh; Pattison & Shattuck, which means also J. J. Hill; Hoffman, of Cincinnati; Loveland and Smith, of Duluth; and Lindsay and Talbot; all of which, taken collectively, and with affiliated interests, leaves few of the operators in copper not accounted for.

due to defective cam-shafts supplied by the Allis-Chalmers Company.

Mexico City.

Interest in Mexican Mining.—Copper Interests at Cananea.—Zinc Mining.—Monterrey and Chihuahua.—Development of Oil-fields.—General Activity.

If, notwithstanding the prosperity that seems everywhere in evidence in the United States, the cycle of years has run its course, and a panic is due in the United States, so that home capital, as well as French, German, and English has become wary of investment therein, no better field to which to turn could possibly be found than Mexico, where the finest opportunities are given, and from the amount of foreign capital which is being invested in the Republic, it would appear that a boom in Mexican enterprises is about due, if not already on. Many newspaper men are writing on Mexico, and even devoting entire editions to this country, as are also some of the semi-technical and financial publications, and, by this free advertising, the attention of investors is being rapidly drawn hither, especially when it is learned that there is scarcely a legitimate business that, if intelligently entered into, will not lead to a rapidly successful issue. And this is perhaps even more true of mining enterprises if preceded by anything like the proper kind of caution and investigation. What has been done in the copper

Likewise in zinc, the world's principal dealers are looking to Mexico for a large part of their supply, though as yet, unlike the case in copper, no zinc smelters have been erected in Mexico. The wonderful production during the last two years of zinc ores from the Villaldama, Sabinas Hidalgo, and Vallecillo, in the State of Nuevo Leon, together with the proximity of the Coahuila coal-field, led to considerable talk for some time regarding the building of a zinc smelter at Monterrey, but it has come to naught. The supply of zinc ores for the Monterrey market, however, is sufficient to keep alive the agencies for the Empire Zinc Co., the Edgar Zinc Co., the American Metals Co., the Cockerill Zinc Co., and the Minerals & Metals Co. (or the Peñoles Mining Co. of Mapimi, the Mexican end of the Metalgesellschaft of Frankfurt), whose competitive bids make a zinc mine almost more to be desired than a gold mine, and many men have already made themselves rich on zinc in Mexico (where its value even yet is not widely known). Operators with small capital have quietly got hold of zinc properties that were thought practically worthless because they had no lead, silver, or gold. But it is not alone in the Monterrey district that zinc is being eagerly sought. At Charcas, in the State of San Luis Potosi, the Tiro General (J. G. Creveling, Jr., president and general manager) is putting in a Sutton-Steele dry separator; and Arthur Pallandt has been shipping zinc ores for years from this camp to the European market. It is to the State of Chihuahua, how-

ever, one must turn for the largest zinc mines of the Republic. These are the El Potosi, of the company of that name, in the Santa Eulalia district, near the city of Chihuahua, and the Calera, of the Calera Mining Co., near Miñaca, the terminus of the Chihuahua & Pacific railroad. This latter mine is shipping about 100 tons per day of a lead-zinc sulphide, part to Canyon City, Colo., and part to L. Vogelstein & Co., New York. From the Potosi only about 30 tons per day, or 1,000 tons per month, of zinc carbonate is being shipped, which, however, could be greatly increased, as its zinc deposits alone are enough to make Santa Eulalia famous, but the company is giving most of its attention to its silver-lead ores, which are being shipped to the American Smelting & Refining Co.'s plant at El Paso. The zinc of the Monterrey district is mostly an oxide and that of Charcas a sulphide.

But it is not alone to copper and zinc that capital is turning in Mexico. A \$50,000,000 company has just been organized to exploit on a large scale the well-developed oilfields of San Luis Potosi and neighboring States. Several million-dollar companies are but lately formed to open up new lands covering the Coahuila coal-beds. The great success of the cyanide process in the treatment of the silver ores of Guanajuato has drawn additional capital there, and led to influx of new capital with the cyanide process in the old camps of Pachuca and Zacatecas. Wherever you may turn there is new work with excellent results, and new railroads building or contemplated are bringing distant mining districts into touch with the world.

Toronto, Canada.

Meeting of American Institute of Mining Engineers.—Papers by W. P. Blake, James Douglas, G. B. Lee, and W. L. Saunders.—Interesting Sessions.

The annual summer meeting of the American Institute of Mining Engineers was held at the King Edward hotel, Toronto, commencing on Tuesday, July 23. About 200 members were in attendance, accompanied by a number of ladies. At the opening session the chair was occupied by John Hays Hammond, the president. Alderman J. J. Graham, on behalf of the city of Toronto, extended a cordial welcome to the delegates; this was appropriately acknowledged by the president.

James Douglas, of New York, presented to Rossiter W. Raymond, the secretary, his portrait in oils as a recognition of a long term of service. In the course of his reply Dr. Raymond expressed his pleasure at the meeting of the Institute in Canada, saying that the word 'American' in the title of the Institute was not political, but continental in its significance. It was announced that an honorary membership had been conferred on Charles D. Walcott, until lately Director of the Geological Survey of the United States. W. P. Blake read a paper on the destruction of the salt industry at Salton, San Diego county, Cal., by floods due to the overflow of the Colorado river, causing losses amounting to hundreds of millions.

James Douglas presented a thoughtful paper entitled 'Some Reflections on Secrecy in the Arts,' being a strong plea for the interchange of opinion, and the free communication of experiences to facilitate the solution of technical problems. Many large manufacturing and mining concerns imposed no restrictions in this respect, though others did. If it depended upon technical workers these barriers would be broken down, as there was no diversity of opinion as to the need of open mindedness. Technical science could only progress through the co-operation of many workers. He cited Michael Far-

aday, Rontgen, and other scientists as examples in this respect, and contended that if secrecy were abandoned and every encouragement given for co-operation and mutual help, much more rapid advances would be made. Too much secrecy and suspicion had resulted in the decline of the copper smelting industry in England. Every limitation meant concealment of some fact or principle which needed to be made public in order to secure its full development. E. W. Parker, of Washington, read a paper on the condition of the coal briquetting industry of the United States.

In the evening a reception was held at the Parliament building, which was profusely decorated for the occasion. The visitors were received by Chief Justice Moss, acting Governor, and several ladies. The Minister of Lands and Mines presided. Chief Justice Moss and others made addresses of welcome which were fittingly responded to by Messrs. Hammonnd, Raymond, James Douglas, Hunt, and Blake.

On Wednesday R. W. Raymond read a communication received by James Douglas from G. B. Lee, superintendent for the Copper Queen Consolidated Co., at Douglas, Arizona, calling attention to a peculiar case of the corrosion of water-jackets of furnaces. A water-jacket, taken from a new furnace in use for five months, was found to have the inner sheet badly pitted, while the outer sheet did not appear to have been attacked. The rotary pumps circulating water for the condensers, made of cast iron, were also badly pitted at certain points, being eaten away one-quarter inch for a space of one or two inches close to spaces not attacked. No action at all was detected in the boilers, which, after being in use for 2½ years, were reported by the inspector as being in excellent condition. The water, obtained from wells 500 ft. deep, had been repeatedly analyzed without detecting anything that could explain the corrosion. The company is substituting a water-jacket of charcoal iron in the hope that this will not be attacked as badly as the steel. Samples comprising a staybolt and a piece of metal showing the ravages of corrosion were forwarded in the hope that some of the members could explain the cause.

William L. Saunders, of New York, presented a paper on 'The Electric Air Drill' which he stated was the only drill ever constructed for the drilling of rock by electric power that was commercially successful. Electricity is supreme as a means of conveying and directing power, and the problem of applying it effectively to rock-drilling had been before mining engineers for 20 years. Sixteen years ago Edison thought he had solved it but the solenoid drill had proved a failure because it had not the power of pull requisite. Altogether he estimated that some \$800,000 had been spent before success was attained by the adoption of the principle of air pulsation by electricity. This principle was applied to other machines and was utilized for the process of cutting grooves in marble in the Vermont marble quarries in place of condensed air. The consequence was that the quarries were now free from the fog produced by condensed air. The Ingersoll-Rand Co. had installed in mines about 100 electric air-drill plants, which were giving satisfaction. A distinctive difference between the electric-air and compressed-air drills was that in the former the cylinder was built without valves and the chuck was a steel casting of a more simple character, dispensing with bolts. The paper was illustrated with views showing the drill at work. The reading of this paper was followed by a general discussion. In answer to questions, Mr. Saunders explained that the drill gave a peculiar stroke, combining a pull and a push, the compressed air acting like a spring in forcing the drill back and rendering it easy to extract when caught in the rock. The cost of the drill

was about 20% higher than an air-drill equipment, but the saving in fuel amounted to at least 50 per cent.

Robert Bell, of Ottawa, read a paper on the 'Tar Sands of the Athabaska District.' He stated that he did not know of any district in the world where there was so great an accumulation of tar sand due to the outpour of petroleum, as existed in the Athabaska valley. The tar sand covered an area of 1,350 square miles at an average depth of 150 ft. There would be about 11,000,000 tons of tar substance apart from the sand, and it was a valuable deposit, which might be utilized for the manufacture of oil or for fuel, paving, and roofing purposes. Eugene Coste corroborated the statements of the paper as to the extent of the area impregnated with tar. It was impossible, he held, that it had come from fossils, but it was due to volcanic emanations of which there was evidence in every oilfield. Geologists had never considered how much the gaseous emanations from the centre of the earth had affected the geological formations. Prof. Bell held that petroleum had a vegetable origin.

At the afternoon session the leading feature was a paper by Willet G. Miller, Provincial Geologist of Ontario, on the Cobalt mineral area with limelight views. Cobalt, he said, was unique in its association of ores. In no other part of America did the metals of silver, cobalt, nickel, and arsenic occur together. The only known places where they were found in combination were Saxony, Bohemia, and one place in France. Most of the noted mineral deposits of Ontario were unique. The nickel ores of Sudbury required years of experimenting for their profitable treatment. The corundum and mica deposits were also phenomenal. The Cobalt mines had been rapidly developed because the ore was so rich in silver, but owing to its peculiar and refractory character the cobalt, nickel, and arsenic had been practically wasted. The speaker accounted for the peculiar character of Ontario minerals on the ground that the rocks of Ontario were of an older formation than those existing east and west. The silver-yielding veins of the Cobalt area were mostly in the Huronian formation, some in the Keewatin, and some in the later diabase, but on coming to the Keewatin the silver in a vein sometimes stopped, while the cobalt and nickel continued. A reproduction of an old map of the country, dating back to 1744, was shown with the name, Baie de la Mine, indicating a locality on the east side of Lake Temiskaming. This had reference to the galena deposit known at that time, but had the French discovered the riches of Cobalt the destiny of the country might have been changed. The rich silver-yielding area of Cobalt was comprised within six or seven square miles. The newer discoveries on the Montreal river had not yet been worked out in detail, and it was not known how far conclusions drawn from the formation of the Cobalt area were applicable to them.

Alfred E. Barlow, of Ottawa, gave a paper on the Sudbury nickel area, illustrating the peculiar position of the orebodies which are all situated at the border of a laccolithic mass as the result of magmatic differentiation, though no doubt also influenced by secondary action. These deposits were characterized by marked uniformity, one orebody being much like another. The Creighton mine had reached a depth of 300 ft. At present only two of the mines were in operation, the Victoria by the Mond Nickel Co., and the Creighton by the Canadian Copper Co. In all, ore valued at about \$50,000,000 had been taken out.

This concluded the meeting, a large number of the members leaving the same evening on a special excursion under the auspices of the Provincial Government to Cobalt and other mining regions of northern Ontario.

New York.

Operations of the Guggenheims.—Several Recent Disappointments.—Morgan's Co-operation.—New Coalfield.—Consolidation of Ely Copper Mines.—Probable Opposition.

The Guggenheims have been the subject of many rumors lately, and all of them suggest financial embarrassment. In California, the Dairy Farm mine (in Placer county), which cost \$600,000, has proved a disappointment, and the Balaklala deal (in Shasta county) has ended in a fizzle. Until lately the Guggenheims held 80,000 shares out of the 525,000 issued, the control being with McCornick and Brevoort. It was arranged that the Balaklala matte should be sent to the A. S. & R. smelter, and that, in return, the Guggenheims should furnish money to build the smelter at Coram. But this they failed to do, the contract was broken, and a new one is under discussion. On the top of this comes the abandonment of the scheme to build a large copper smelter at San Bruno, near San Francisco. No wonder that the gossips have been busy. It is stated that 200,000 shares of the A. S. & R. stock were sold at \$80 at a time when the market stood at \$108, and that this forced sale was made to the Standard Oil people, in fact, a well informed engineer, borrowing the simile of the roulette table, said that "when the wheel stops, it will point to Amalgamated Copper," meaning that a counting of shareholdings in the smelter trust will indicate that the Guggenheims have lost control to the people identified with the Amalgamated Copper Co., that is, H. H. Rogers, Rockefeller, and the Standard Oil group.

There has been talk of Mr. J. P. Morgan becoming associated with Mr. Daniel Guggenheim and his brothers, and the nature of the explanation for this event in *haute finance* has varied from a statement that it meant a great consolidation of heavy capitalists to the inference that Guggenheim was associated with Morgan in the sense that Jonah was associated for a time with the whale. As a matter of fact it is known that the Guggenheims have long wished to obtain the support of Morgan and it was regretted by Mr. Daniel Guggenheim that his mining and smelting companies were not underwritten by that famous art collector. As to the sale of 100,000 shares of A. S. & R. stock to Morgan in order to extricate two Guggenheims who had speculated neither wisely nor well, that story may be founded on the fact that some of the Guggenheim employees have been unfortunate on Wall Street lately.

The transfer of a ten million dollar interest in the smelter trust is likely to be a part of a Morgan participation with Guggenheim in Alaska. It will be remembered that the Morgan and Guggenheim interests have worked together over the Copper river railroad and copper mines. In their railroad scheme they have fought the White Pass people in a contest over right of way. More important even than the copper mines is the coalfield at the foot of Mt. St. Elias, to exploit which a strong consolidation has been formed this week. A semi-anthracitic coal has been found in quantity sufficient to make it a factor in the development of the Pacific Coast; any mineral development that will break the high prices now paid in San Francisco is likely to be welcomed.

The *Boston News Bureau* states that daily conferences have been held looking to the taking over of the Nevada Consolidated and Cumberland & Ely properties into the Consolidated Copper Co., recently organized by the Guggenheims, and it is stated that the basis of the deal is to be 2½ shares of Copper Consolidated for 1 Cumberland & Ely, and 3 shares of Copper Con. for 1 of Nevada Consolidated. This is unlikely, for according to reliable

information the best Cumberland & Ely can do is to show 1,000,000 tons of ore as against 20,000,000 in the Nevada Consolidated. It is true the former claims a better grade of ore, but it is too poor in iron for direct smelting and too high for economical concentration, permitting only of concentration in the ratio of $2\frac{1}{2}$ or 3 into 1, as against about 7 into 1 with the Nevada Consolidated ore. The *News Bureau* forgets that there is a large holding of Nevada Consolidated in San Francisco and it is stated that the shareholders in question are prepared to present an effective opposition to any further juggling with their interests.

Cripple Creek, Colorado.

Activity Among Lessees.—The Portland Tax Suits.—Deep Mining.—Strike in the Henry Adney.—The Findley.

Shipments from Bull hill show the activity of a number of lessees. From the Brooklyn, of the Stratton estate, H. P. Reiton has shipped a carload to the Golden Cycle mill at Colorado City, expecting returns of \$25 per ton. Manee & Co. were shippers from the Wild Horse to the Golden Cycle mill, while some half dozen other lessees contributed carload lots of an average grade to the general output: O. A. Carper from the Pinto-Bison, a \$30 consignment, the Union Leasing Co. and the Standard M. & D. Co. substantially aiding the output.—The Isabella is breaking ore four feet wide on the 900 and 1,000-ft. levels, neither hanging or foot-wall is as yet exposed. The opening of this orebody is a great addition, from all accounts, to the present value of the property. Drifts on the orebody continue to prove its extent, the stope being opened for a hundred feet, on company account. Lessees are also operating in ore of good grade under the management of John Sharpe for the Colorado State investment Co. Seventy-five feet of drift has been done and stoping is now in progress, while regular shipments are being made. The Isabella mill is in operation, about 100 tons per day being put through; ore running \$4 per ton is taken from the dump and low-grade portions of the mine.

The Portland company is under the fire of an Iowa court in the matter of taxation, \$100,000 of taxes being in question, and the County Treasurer, of the county in which Council Bluffs is situated, and where, until recently, the annual meetings were held, has nearly a thousand suits pending against individual stockholders. The present litigation will no doubt decide the issue in all the cases. Originally the Portland was incorporated under the laws of Iowa, to be later re-incorporated in Wyoming. The Portland is conducting development work at a depth greater than that undertaken by any other property in the district. On the 1,200-ft. level winzes have been sunk to prove an orebody that has given returns of an ounce to three ounces per ton. No. 2 shaft is to be sunk 150 ft. below the 1,200-ft. level and a station cut and laterals run; this to be known as the 1,350-ft. level, though the actual depth is over 1,500 ft. below the surface. Operations at this depth will be watched with interest.

The Henry Adney, the steady producer of Beacon hill, comes forward with a reported strike of exceptional merit. Drifts are in progress on a 15-ft. vein between the 400 and 500-ft. levels and a seam $4\frac{1}{2}$ in. wide was encountered assaying as high as \$28,000 per ton, with grab samples from the muck pile of \$2,450. Ore is being broken between the 500 and 600 levels 3 ft. wide, giving returns of two ounces per ton.—The Findley requires more room for dumping ground and has ordered persons owning dwellings on its property to remove same at once; when this is done cribbing will be put in place on the vacated ground, thus increasing the dumping area.

Butte, Montana.

Butte Continental.—British Butte.—Butte & Bacorn.—Shortage of Coal.—Heinze and His Partner.—The New Departure.

George L. Spangler, of Duluth, representing Minnesota capitalists, has been examining the property of the Butte Continental Co., in which he is interested. There is one big vein on the property, and it is believed that shipping ore will be found at a depth of 500 ft. Arrangements are being made to sink a two-compartment shaft. The company owns 10 claims. The present capitalization is 1,000,000 shares at \$1 per share.—Charles Olden, who came from London to make an examination of the placer property of the British Butte Mining Co., has gone back to England to recommend the installation of a dredging plant. The property is situated about four miles west of Butte. The company has purchased the head-frame and other machinery used by the Butte Exploration Co. at the Six O'Clock mine. Two 80-hp. boilers have been installed, doubling the steam capacity, and cages have been put in the shaft.

The Butte & Bacorn Mining Co. has finished cutting a station at 1,000 ft. in the shaft on the Calumet, and has

Montana.

started cross-cutting north and south. The north cross-cut is to be run nearly 900 ft. to connect with the shaft on the Belinda, but it is expected that at least one vein will be cut within 100 ft. of the station. Everybody in Butte is watching with great interest the progress of the work, and the developments by the cross-cuts, for if the Butte & Bacorn finds ore in the veins in that portion of the Butte district, it will prove the extension of the productive territory. The Butte & Bacorn property is about two miles north of any other developed property. It has been freely predicted by mining men, however, that the Butte & Bacorn will find that 1,000 ft. is not sufficient depth for finding ore. Some exploration work was done on the 500-ft. level, and several well mineralized veins were opened, but they carried no commercial ore.

Walter L. Steele, of Dallas, owner of a system of dry concentration and separation, has made arrangements with the La France Copper Co. of Butte for the installation of one of his plants in Butte. Several of these plants are said to be in successful operation in Mexico and Arizona.—O. M. Best, manager of the New Departure mine, reports that the cross-cut from the 50-ft. station below the adit level has penetrated a vein of rich ore. The point of the strike is about 350 ft. below the surface; ore is being broken at several places in the mine.

The Butte Reduction Works is still short of fuel, and the manager complains that the railroads cannot supply sufficient coal. Only a small portion of the orders can be

filled, and the situation already presents a serious problem for the coming fall and winter. As it is impossible to get sufficient coal to supply the smelters at this season, it appears certain that the supply during the winter will not meet the demand.

The litigation in which F. Augustus Heinze has become involved through a disagreement between himself and his former banker and business associate, Thomas M. Hodgins, has resulted in an attachment of Heinze's interests in the Silver Bow National bank and the State Savings bank of Butte. He owns controlling interests in the two institutions and is supposed to have money on deposit in both banks. According to the claims of Hodgins he entered into a partnership with Heinze early in last year for the purpose of investing and speculating in mining stocks. He says Heinze purchased for their joint account a lot of Amalgamated and Anaconda stock. He sold some of it and realized good profits, but other shares he held too long and lost money. Hodgins says Heinze has never accounted for his part of the partnership business. He also says that under the same agreement he purchased during three days in February, 1906, 3,350 shares of Bingham Consolidated stock for himself and Heinze, paying on the open market a total of \$133,980 for the stock, paying \$38 to \$40 per share for it. He offered half of it to Heinze, under their alleged partnership contract, but Heinze repudiated the agreement and refused to put up his half of the cost of the purchase. Later came the rupture between the two men and suits were brought by each against the other. In the Bingham deal Hodgins sued for \$66,980 and attached the Heinze interests in the two Butte banks owned by Heinze. In the Amalgamated and Anaconda deals he has sued for an accounting. Heinze has also sued Hodgins for a large sum of money which he is alleged to have misapplied while cashier of the State Savings bank, and his litigation with his former business partner promises to become as noted as the litigation he once had with the Amalgamated.

Denver, Colorado.

Bulletin on Leadville.—News From Ward.—Activity at Telluride.—Freight-Rates on Cripple Creek Ore.—Elkton Dividend.

The bulletin of the United States Geological Survey on the geology and mineral resources of the downtown district at Leadville has at last appeared and is now ready for distribution. The bulletin is issued preliminary to the publication of the revision of the monograph on Leadville, which will not be ready for some little time yet, partly to satisfy the demands for a speedy publication of the results of the examination of the downtown district, and partly in order that any errors that may possibly be discovered in the preliminary work may be rectified. The bulletin should prove of signal service to all those engaged in exploiting deposits in this part of the area. It can be secured upon request to the Director of the United States Geological Survey. Ask for Bulletin No. 320.

The Modoc mill at Ward is being remodeled to adapt it to cyanidation, as the preliminary experiments have gone to show that a high extraction can be made without roasting. Since the company has large reserves of ore blocked out the prospects of success seem exceedingly bright. The mill has experienced much trouble in the past from inability to secure sufficient fuel in the winter. By developing a water power on St. Drain creek 2,000 hp. of electric energy has been made available to solve this difficulty.

The Bear Creek district, near Ouray, which has had a long history of rather indifferent success, is showing

much activity at present. The Blackbird is shipping ore and the Grizzly Bear is also producing some ore of good grade. The Union mill is now in process of construction, and will be ready to start soon. At Telluride, the Columbia-Winona mine and mill have been sold to the Iowa Mining Co., together with the Pay Rock, Champion, and Chieftain groups of claims. John B. Farish is the consulting engineer for the company and it is expected that vigorous development will begin shortly. The Columbine group of claims is also being developed by a Kansas City company. Mining near Rico is active. Hahn's Peak likewise is the centre of a good deal of interest. The dredge recently put in operation by Hutcheson & Stevens is operating satisfactorily on the placer deposits. Another company has been

A Part of Colorado.

organized to operate in the district and has begun exploratory work.

At Cripple Creek, it is announced that the Do Dandy mill has begun operations, and is prepared to treat ores either by the cyanide or 'tubular' processes. Whether the latter involves grinding in a tube-mill or sucking through a straw is not so clear as would be desirable to the enquiring metallurgist.—The disagreement between the mine and mill owners, arising from the recent readjustment of freight-rates, is the subject of a conference between the two opposing interests. While pleased with the reduction of the rates on low-grade ores, the former are not so well pleased with the increased charges on the high-grade ores. Another grievance of the millmen is that the charge to the Colorado City plants is made the same as to the Denver and Pueblo smelters, a discrimination that works to their hardship.—The cave-in at the No. 2 shaft of Stratton's Independence last week did very little damage except to the tracks of the Colorado Midland railroad. The shaft is now practically abandoned, and the cave, which extended to the 300-ft. level, simply filled the old stopes and levels.—At the annual meeting of the Elkton Mining Co., all the old officers and directors were re-elected. The total production for the year was \$682,500, and the net profit \$347,000, or a profit of 51% on the gross value of the ore, which shows an economical management. The Elkton stands second of the Cripple Creek mines in the payment of dividends.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

TO TEST the quality of boiler iron, bend it, cold, at sharp angles and double the pieces together; heat the piece to a cherry red and perform the same operation; punch holes very near the edges of the sheets, and if it stands these tests without cracking, it is neutral iron and considered to be of the best quality.

IN the Tertiary rocks of California gypsum is widely distributed. It is found throughout nearly all the coast ranges, particularly south of San Francisco bay, in the foothills of the Great valley, and in the valleys of southern California. Deposits are known to occur in the counties of Fresno, Ventura, Kings, Monterey, Kern, San Luis Obispo, Santa Barbara, Los Angeles, San Bernardino, Riverside, and Orange.

HESSITE is a silver telluride, in which gold is often present replacing part of the silver; in this way it graduates toward petzite. It crystallizes in the isometric system, but the crystals are often highly modified and distorted. The cleavage is indistinct, the lustre metallic, and the color between lead and steel-gray. Typical specimens have been identified in this country from Calaveras county, California, Boulder county, Colorado, and Dry Canyon, Utah.

IN the White Cliffs opal district of New South Wales there occur many pseudomorphous forms of opal after shells, crinoids, saurian bones, and coniferous wood, and there are also curious masses of grouped crystals, known locally as 'fossil pineapples,' representing the replacement of some mineral not clearly determined. A paper has appeared in regard to these problematic bodies in which we are led to believe that the original mineral must have been glauberite.

GYPSUM can be obtained in quantity at several localities in southern Arizona, the following being particularly noteworthy: In the Santa Rita Mtn., Pima county, southeast of Tucson; in the low hills along the course of San Pedro river, Cochise and Pinal counties; in the Sierrita Mtn., Pima county, south of Tucson; in the foothills of the Santa Catalina Mtn., Pima county, north of Tucson; on the Fort Apache reservation, Navajo county. Of these districts only the fourth, north of Tucson, has as yet been commercially developed.

CONSIDERABLE quantities of the mineral cryolite are imported from Greenland each year for use in the manufacture of sodium salts. In the processes of manufacture calcium fluoride results as a by-product, and is saved to be sold for use as a flux in open-hearth steel furnaces in the same manner and with the same results as the natural calcium fluoride, or fluorspar. The quantity of the artificial fluoride made depends, of course, upon the quantities of cryolite treated, and is said to be usually from 3,000 to 4,000 short tons per year.

COMPRESSED-AIR LOCOMOTIVES work under pressure ranging from 500 to 2,000 lb. per sq. in. The pressure is determined mainly by the size of the locomotive permitted by the dimensions of the tunnels and curves. In tunnels of good size the large reservoirs required by low-pressure engines are permissible, but where only small reservoirs can be used it is necessary in order to carry the supply of power required to compress the air to a

higher degree in the steel tubes, which are made of such a strength as to safely carry the pressure.

SALT occurs in vast quantities in the deposits found in the ancient lake basins of the southern part of California, but the only commercially productive deposits of this character have been flooded by the recent diversion of the Colorado river into the Salton sink and thus removed from consideration. The great production which puts California into the sixth place in order of output among the States comes from the evaporation of sea water, the conditions for which are particularly favorable on the east side of San Francisco bay in Alameda county.

HARDENING AND TEMPERING steel is effected by heating it to a cherry red and plunging it into a liquid, generally cold water. The degree of hardness depends on the heat and rapidity of cooling. Steel in its hardest state being too brittle for most purposes, the requisite strength and elasticity are obtained by tempering, which is performed by heating the hardened steel to a certain degree and cooling it quickly. The requisite heat is usually ascertained by the color which the surface of the steel assumes. A straw color is commonly used for cold chisels and machinists' tools.

LATE developments in the application of rotary furnaces, similar to those employed in the manufacture of cement, to the treatment of fine iron ores, principally pyrite, clinker, blue billy, and flue-dust from blast-furnaces, are to desulphurize them and to form the fine material into nodules of such form and texture as will permit of transportation to blast-furnaces, and of delivery of this material to the smelting zones. This process makes available ore which, either because of its sulphur contents or its fine state of comminution, was considered undesirable, and also reduces the loss of ore due to modern methods of charging blast-furnaces and of operating them with high blast-pressure.

THE flicker photometer, when introduced, seemed to offer advantages enjoyed by no other instrument. It depended for its action upon a peculiar effect to which the eye is more or less sensitive, and did away with the necessity for comparing two surfaces. In other words, surfaces illuminated by the two sources being compared are brought alternately into the field of vision. When illumination on the two surfaces is equal, no variation is seen, and the flicker disappears. There has been some question, however, whether this instrument is a true photometer—that is to say, whether the effect produced in the eye by the flickering surface is proportional to the illumination of the surface, or whether other effects may not creep in, and thus vitiate the measurement.

THE diamond deposits of Brazil have been worked since the early part of the 18th century, and have yielded well, although at the present time the yield is rather small. The most important region was that near Diamantina, in the province of Minas Geraes. It is situated along the crest and on the flanks of the ridge that separates the Sao Francisco river and its branches from the Jequitinhonha and Doce rivers. The diamonds are obtained in part from river washings and in part from prairie washings, as on the high ridge known as the heights of Curralinho. The river deposits consist of rolled quartz pebbles, mixed with or cemented by a ferruginous clay that usually rests on a bed of clay. The diamonds are most plentiful in large pot-holes in the bed-rock. In the upper plateau diggings the diamonds occur in part in a conglomerate, and some are reported from a quartzose schist in a region farther to the north.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A Fundamental Problem.

The Editor:

Sir—In your issue of June 29 under the caption of 'A Fundamental Problem' you discuss a subject which is truly at the bottom of all the principles upon which the mining industry is based. The advice you gave to the broker is thoroughly judicious. One line in it suggests to me some thoughts, which I offer herewith.

The line was, "Get good technical advice. If you can't pay for it stay out of the game." Previously in your article you had raised the question, "Is mining only a gamble after all?" Now, what is a gamble and what is mining? According to the Century dictionary a 'gamble' is a "speculation, dependent for success chiefly upon chance, or unknown contingencies." A comprehensive definition of 'mining' would be: First, extracting from the earth mineral of which the amount and value have previously been determined; second, the searching in the earth for the mineral that it is hoped will be found there.

Now, in the first division of this definition there is probably a smaller percentage of chance than attends any other mechanical operation. Everything is subject more or less to chance and the unexpected sometimes happens, in spite of the most accurate calculations; for instance, the recent wreck near Santa Barbara on a straight track in broad daylight, the tidal wave at Galveston, the conflagration at San Francisco, the fire in the Homestake mine. But such catastrophies do not render business undertakings 'gamble.'

In the second division of the definition there is gambling if the results are "dependent chiefly upon unknown contingencies." The lower levels of the Gwyn mine had been flooded and inaccessible for years. A mining engineer who had not been underground in the mine at any time in its career sunk a new shaft, and while sinking built an elaborate mill. At a depth of 1,400 ft. in the shaft ore was struck, the stamps began dropping, have continued to drop ever since, and dividends have followed each other with gratifying frequency.

Two soldiers of fortune secured a lease on a mining claim with no record and sunk a shaft. After a time the Mohawk was producing gold faster than it ever came out of a new mine before in mining history.

Both of these cases come under the second division of the definition. The first was not gambling; the second was. Why? Because in the first place a mining engineer of proved experience had informed himself from the record of the Gwyn what had been the nature of the vein while it was being worked and approximately what had been extracted; hence by deduction he inferred what was likely to come out.

The second was gambling, because the physical conditions were not such as to enable a mining engineer to predict with assurance any deposit at all.

The Guggenheim Exploration Co. buys mines. When one is offered which presents sufficient evidences of value to insure consideration, the Guggenheims send one or more of the most competent mining engineers available to measure and compute the amount of ore disclosed, and estimate the cost of its extraction. It then has other engineers take the report of the first and calculate the cost of converting the ore into metal. By ordinary subtraction it finds the sum representing the net money, and with that information it negotiates for the mine, which,

if purchased, is operated under the first division of the definition of mining.

The broker knows what happened at the Mohawk and builds air castles. He calls in a mining engineer of the camp and asks the question, "If I secure a certain piece of ground (naming it) and work it, what are my chances?" The mining engineer looks at it and replies, "They are just as good as were those of the Mohawk at the start." The broker thereupon raises the money and—gambles, the very worst illustration possible of the second division of the definition. He strikes—nil. Who is to blame?

Now does this mean that no one but the Guggenheims and others in their class can mine without gambling? By no means. There are opportunities to purchase mining properties (at reasonable figures), which the experienced engineer is justified in believing will make pay mines. These will not, as a rule, be close to populous camps where everybody sees them. They may belong to prospectors in some remote field. They may have been once worked and abandoned and filled with water and waste. They may contain a valuable mineral unappreciated by the claimant. They may have such composition that new conditions (a concentrator, a railroad, some novel means of treatment, the development of water-power), are essential to giving any margin of profit. Their value may be potential only and the mining engineer is the man who alone can adequately discern it.

The most successful mining engineers and individual operators have secured their greatest successes by employing mining engineers and sending them out under general instructions to ferret out just such opportunities. There are chances involved, but these are fairly compensated by the law of average.

Let any one think over to himself the names of all the successful mining men and corporations familiar to him and also the names of all those who were once successful and failed; then let him figure the percentages of failures to successes. Then let him compare that percentage to the percentage in any other kind of business. That would be the test of whether mining is gambling and not the experience of the broker that wrote to you, however well meaning or honest he may have been.

JAMES W. ABBOTT.

Pioche, Nevada, July 13.

A Correction. Oaxaca.

The Editor:

Sir—I have read with interest the remarks in your number of June 29, under 'Mexico City,' on the Oaxaca Smelting Co. and the Magdalena smelter. I would, however, beg the hospitality of your columns for the purpose of making a few corrections in your correspondent's statements, which as they stand are somewhat misleading.

Firstly, the name of the company owning the properties on which is situated the Magdalena smelter is not Williams & Hamer, but L. R. Hamer & Company.

Secondly, though your correspondent stated quite correctly that an option was at one time held on these properties by the Oaxaca Smelting & Refining Co. for the sum of P550,000, on which P20,000 forfeit was paid, he omitted to add the rather important fact that said option merely covered a half-interest.

Thirdly, I beg to state that there never has been, nor is there the slightest likelihood that there will be, any arrangement between my company and the Oaxaca S. & R. Co. The completion and blowing in of the plant of the latter company are matters which in no way concern my company, nor were we in any manner, directly or indirectly, connected with their operations.

Fourthly, the freight and treatment charges in Oaxaca

are not held at P42 per ton, as we, operating the only steadily running smelter in the district, have treated custom ore as low as P22.50 per ton, and our highest charge has never gone above P30.

I may add that so far from proposing to make any combination with any local interests, we are about to erect another smelter of 80 tons daily capacity for the treatment of pyritic ores, of which we have enormous bodies. The machinery for this smelter is already on the ground, and erection will begin very shortly.

L. R. HAMER.

Oaxaca de Juarez, July 10.

An Abandoned Project.

The Editor:

Sir—Your editorial in the issue of July 6, regarding the cessation of work on the San Bruno plant of the Guggenheims, calls for comment.

While not doubting the accuracy of your information as to the failure of the Dairy Farm mine at 500 ft. depth, I do seriously doubt the statement that this was the cause of the stoppage of work on the smelting plant. Why not be straightforward about it and say that it has been costing the Guggenheims so much more for labor, material, and time, to build this plant, that when to these troubles the threat of anti-smoke agitation came up, they accepted any fair excuse to stop the work and parley with their neighbors.

I am in no way connected with the Guggenheim companies, but I do know that they are not the kind to throw away money by building at the highest prices for everything, when, by waiting at little loss to themselves, they can gain so much. The failure of any one mine in this or adjoining States would not stop such an enterprise as this, for its tonnage must be made up from the shipments from many mines and where one will fail many will open up to take its place. I know personally that there are many producers of ores such as the Dairy Farm mine contains, that can and would take its place. The 'smoke question' is no doubt a more serious one, and the recent action of misinformed and prejudiced juries and courts in other localities, is a great menace to the industry in general. When the plant of a great smelting industry is equipped with every means for the abatement of the smoke nuisance, the question of the greatest good to the greatest number of people should have weight.

If we cannot build smelters in the hills because we may destroy a few scrub pine trees, and we cannot build them at tide-water on account of the golf links and dairy ranches, where are we finally to land?

There are mechanical means at hand and known to those skilled in the art, to so settle and filter and dilute the gases which finally pass from the chimneys, that damage to the neighborhood is reduced to a minimum. Not all plants now under fire of the agitation are thus equipped, of course, but surely the art of smelting must not stand still on account of the past sins committed in its name.

Such a plant as that at San Bruno would be of immense benefit to the State, and the few who might be harmed by its fumes ought not to be allowed to hold up such an enterprise.

JAS. W. NEILL.

San Francisco, July 14.

[Our friend Mr. Neill is reasonable in his criticism. Of course, we do not know what is going on in the minds of the Guggenheims, for to ascertain that might need some deep soundings, and the Dairy Farm mine may have been saddled with too much responsibility for the abandonment of smelting at San Bruno. It is likely that the

activity of the smelting companies in Shasta county was also a factor. We are inclined to belittle the smelter smoke agitation started by the people of San Mateo, because, as Mr. Neill says, it is possible to minimize the trouble from fume if only enough care is taken, and no coterie of farmers or polo-players can stop an industry so basic as that of smelting.—Editor.]

Secondary Ores of Copper.

The Editor:

Sir—In your Butte letter of February 23 reference is made to a recent development in the mines of the Anaconda Company, as having cut the Anaconda vein in the Neversweat mine at 2,400 ft. deep. The orebody is stated to be "60 ft. wide, with 40 ft. nearly all copper glance, running 60% copper."

In a former letter from the same source reference was made to a discovery in another Butte mine—the Anaconda, if I remember correctly—where ore up to 90% copper was found. This statement was manifestly incorrect and rendered unreliable the remainder of the letter, which otherwise was most interesting.

What one wishes to ascertain is whether this last statement as to 40 ft. of 60% copper ore is an actual fact or another random shot—this time within the bounds of possibility, since chalcocite can contain 78.8% copper.

In a letter of mine of November last to the *Mining Journal* of London I drew attention to the copper of the world being produced mainly from the enriched sulphides (chalcocite principally), and not, as formerly presumed, from the lean sulphide, chalcopyrite. I am pleased therefore, to note in your issue of March 30 an article from no less an authority than James F. Kemp, in which he states, "Today, on the contrary, in the United States and Mexico chalcocite furnishes much the largest part of the copper produced." Another interesting feature pointed out in this article is the possibility of chalcocite being regarded not as a secondary mineral necessarily but of original deposition. For some time bornite has been questioned as essentially a mineral of secondary deposition. If, however, both bornite and chalcocite are invariably secondary minerals, it is pointed out that such deposition may just as well be caused by uprising solutions of copper, as suggested by W. H. Weed, and not necessarily by solutions of oxidized copper salts in descending surface waters.

There would appear to be some interesting developments as to the origin of the enriched sulphides in the near future and the probability of encountering such sulphides as far as mining operations are practicable.

H. E. WEST.

Spassky, Siberia.

[Mr. West, being in Siberia, had not received our issue of June 15, in which it was explained that the rich ore from the Receiver mine, at Batte, consisted of native copper in gouge. It was not the Anaconda mine that was mentioned, but the Receiver, on the eastern side of the Silver Bow valley. Further discussion concerning the genesis of chalcocite ore appears in our issue of July 14, where Mr. Horace V. Winchell makes some suggestive observations, based on an intimate knowledge of the subject. Meanwhile, if the mining people in Siberia have read James F. Kemp, they are not without illumination.—Editor.]

STEEL is a compound of iron and carbon in which the proportion of the latter is 5 to 1%, and even less in some kinds. Steel may be distinguished from iron by its fine grain and its susceptibility of hardening by immersing it when hot in cold water.

Geology of Jamaica, as Related to Its History.

Written for the MINING AND SCIENTIFIC PRESS
By ROSSITER W. RAYMOND.

Sundry authors, among whom the late Prof. N. S. Shaler was one of the most eminent, have traced and emphasized, with respect to particular regions, the effect of geological characters upon human history; but I do not recall any published discussion of this interesting theme with special reference to the island of Jamaica, which furnishes, perhaps, one of its most striking illustrations.

It is not my purpose to offer in this article a complete scientific statement of the geological history of Jamaica. That work has been thoroughly and brilliantly done by a distinguished American geologist, Robert T. Hill, whose researches in the West Indies have been published in a series of monographs by the Museum of Comparative Zoology of Harvard University. I can only regret that the edition of these valuable papers is so small that neither my private library nor that of the American Institute of Mining Engineers contains them, or has thus far been able to secure them. In my study of Jamaican geology, I have been indebted to Mr. Hill himself for the loan of his own private copy, which I have read more than once with much interest and profit, and which constitutes not only the latest, but also unquestionably the most illuminating authority concerning a problem complicated with many perplexing details, heretofore misinterpreted. These details, however, do not concern my present purpose, for which it is sufficient to set forth the following leading features:

1. The island of Jamaica is the result of two successive uplifts, neither of which is older than the Mesozoic, together with intervening and following changes of level, permitting the deposition, elevation, etc., of sedimentary strata.

2. It stands in the centre of what Mr. Hill calls "the American Mediterranean," encircled by islands which seem to constitute a structural border for that inclosed sea; and it is characterized, as to a part of its shore, by the exceptional depth of the adjacent ocean, indicating, of course, the exceptional steepness of the primary uplifts, making the island, as it were, a precipitous mountain in the sea. This depth of intervening water has prevented, in many cases, the migration to Jamaica of superficial marine species, thus rendering more difficult the correlation of the coastal rocks with those of other islands; but that question does not concern me at present.

3. The causes already mentioned, together with the effects of torrential tropic rains, have impressed upon Jamaica the following geological and topographical features:

a. A central backbone of slates, etc., rising in places to 7,500 ft. or more above sea-level, and deeply and sharply eroded with precipitous canyons, so as to justify the famous illustration of Columbus, who, in describing the country to Queen Isabella, is said to have crumpled a handkerchief and thrown it upon the table before her, as a model of the irregular topography.

b. A plateau, chiefly of limestone, once deposited at sea-level upon the flanks of the aforesaid ridge, but now lifted to a considerable elevation. This plateau, encircling the older nucleus, and much wider in some parts of the island than in others, is characterized by peculiar so-called 'cock-pits,' or funnel-shaped depressions in the limestone, apparently produced by erosion, coupled with the downward drainage of surface-waters through the permeable rock to the harder and steeper strata below. Since, so far as I can learn, the 'cock-pits' are never found filled with water, this inference is irresistible.

c. A zone of cliffs and débris, produced by the breaking down of the plateau.

d. A zone of coral-rock, alluvium, etc., along the shore, sometimes forming extensive coastal plains, but often (especially on the northern and eastern sides of the island) relatively narrow and unimportant, in comparison with the predominant underlying central ridge, which impresses upon the coast-line, in the form of numerous navigable bays, its deeply-marked topography.

4. The geological conditions thus enumerated have been aided by the variety and fertility of the soil furnished by the different rocks, the variety of climate, due to the wide range of elevation furnished by the topography, and the difference in annual rainfall between different parts of the island, caused by the high intervening mountain range.

Having thus outlined those general natural features of Jamaica which are specially concerned in my present thesis, I proceed to indicate briefly their effect upon the history of the island.

1. Unlike almost all of the other regions, insular or continental, which were discovered and exploited by the Spanish, Jamaica seems never to have offered to them the temptation of gold. Indeed, so far as I can discover, nobody, down to the present day, has ever found suggestions, or even dreamed dreams, of gold on this island. As for other metals, there are rumors of copper deposits, and there is a lovely stream, called the River of Copper; but, whatever may lie in the unknown future, it is safe to say that the history of Jamaica has not been perceptibly influenced by that mining enterprise which has been the pioneer of industry and civilization in so many other regions of the New World.

2. But what the geology of Jamaica did not offer in this respect as a stimulus to adventure, it offered in another way as a facility for commerce; for the numerous bays presented by its indented coast became the refuge of ships. For many years, it must be confessed, the sort of 'commerce' thus facilitated was that of the buccaneers. But the business of the buccaneers, after all, was commerce, though complicated with piracy; and if we drop, for a moment, its moral aspects, we must recognize that what these bold adventurers found in Jamaica was the opportunity to hide from their enemies, and to exchange their plunder for the means of riotous enjoyment—which was, no doubt, wicked commerce, but commerce, nevertheless. And after piracy had died out, the advantages of Jamaica as a commercial centre remained. Being founded on permanent natural advantages, they will, as I believe, long continue. Indeed, they will be greatly increased by the completion of the Panama canal.

3. The geology of Jamaica, which had already thus pre-determined its commercial relations, again influenced its history when, during Oliver Cromwell's administration, an English fleet, sent out for another purpose, captured Jamaica, so to speak, by mistake. During the preceding two generations the Spaniards, having deported as slaves all available Caribs, had replenished Jamaica, for the operation of their plantations, with slaves imported from Africa; and when they were obliged to yield the island to the victorious English, they emancipated these African slaves, exacting from them a vow that they would never surrender to those who had conquered their masters. This vow was kept for more than a hundred and fifty years, during which the 'maroons'* inhabiting the recesses of the unbroken tropical jungle of the interior, and aided by their knowledge of the 'cock-

*The word 'maroon' is probably an abbreviation of a Spanish word, meaning 'rubbish' or 'outcast.' The notion that the 'maroons' of Jamaica ever comprised original Caribs, is, I think, an unfounded fantasy. At present, they can scarcely be said to exist as a distinguishable class.

pits' of the limestone plateau, and the intricate ravines of the mountain ranges, defied pursuit. From time to time, they descended in highland raids upon the dwellers below, retreating with their booty to their inaccessible strongholds. Expedition after expedition sent against them was trapped and massacred. They were intensely proud of their savage freedom, and regarded with peculiar scorn and hatred the African slaves imported by the English planters.

At last, they were brought to a treaty of peace, and became, without loss of dignity, the 'allies' of the English. This relation involved for many years no positive action on their part. But in the negro rebellion of 1865 Gov. Eyre called upon his maroon allies, who came down with ferocious enthusiasm and wrought much havoc among the insurgents. No doubt they went further in cruelty and devastation than the Governor intended or approved. This brief but bloody episode was their last historic appearance. They retired into the jungle, where they gradually lost their separate character; and their descendants have melted into the general mass of black inhabitants.

4. Meanwhile, the industrial development of Jamaica had been proceeding, both before and after the English conquest, upon the cultivation of imported exotics. It is a striking fact, that of all the trees and plants which we regard as characteristic of the island, very few are indigenous. The luxurious wilderness seen by Columbus contained no sugar-cane, bamboo, orange, lime, lemon, citron, grape-fruit, coffee, kola, cinnamon, mango, log-wood, nutmeg, rice, or bread-fruit, not to mention many other plants and trees of less notoriety, which, like these, are known to have been introduced from other countries. Whether the cocoanut-palm was present cannot be positively decided. There is no allusion to it in contemporaneous records. On the other hand the giant cotton-tree and the pimento (allspice), prickly pear, guava, paw-paw, wild olive, lace-bark, mahogany, cedar, satin-wood, straw-palm, and, above all, the cassava, were to be seen abundantly by the first European visitors, as they may be seen today.

Of the animal fauna of that day, everything has become extinct except the coney, which is now exceedingly rare. Horses, cattle, sheep, goats, pigs, and poultry have been imported since.

It may, therefore, be fairly said that the natural advantages of Jamaica have been utilized by the artificial introduction of foreign plants, animals, and men. Under the last head, the list comprises the early Spaniards and Portuguese; the slaves brought by them from Africa (the ancestors of the maroons); the English; their African slaves, probably of tribes not related to those which supplied the first importation; and, finally, the East Indian coolies. These Hindus, with their keen Aryan faces, slender and graceful figures, small hands and feet, grave dignity and reticence, and faithful industry, constitute a picturesque and puzzling element of the present population. There are a little more than 10,000 of them. They work mainly upon plantations until their contracts expire, when many of them choose to remain as laborers, shop-keepers, silver-smiths, etc.

The disastrous effects of emancipation upon the Jamaican plantation-industries are well known. That similar prostration did not appear in our own Southern States at the close of the War of the Rebellion, as a result of the abolition of slavery, destroying the plantation system for the culture of cotton, was largely due to the immediate development of cotton-raising by negro owners and lessees of small tracts. The area of the cotton-belt was thus greatly increased; and the crop became larger than ever. But in Jamaica, the production of sugar and

coffee could not thus be continued augmented; and until the development of the fruit business there was nothing to occupy profitably the freedmen who would no longer submit to the conditions of plantation-labor.

This new business, which has become the basis of a new economical progress, owes its prosperity and effectiveness to the old geological features which have done so much to shape the history of Jamaica. More than sixty steamships of considerable size are constantly engaged in this trade; and they collect their cargoes by running into the numerous bays along the coast, so that the native cultivator of bananas, coconuts, etc., no matter on how small a scale, can bring his product to a market with little cost and labor.

Another element of importance is the abundance of excellent macadamized roads,* for which the coralline limestones of the coastal region furnish the best of 'road-metal.' Here, too, the basis of prosperous industry and good government is geological.

On the other hand, it must be confessed that the geographical and geological conditions of Jamaica expose it to occasional earthquakes, cyclones, and droughts of great severity. Of these scourges, the latter two are the worst. The hurricane of 1903 was far more widely and permanently injurious than the earthquake of 1906; and since that earthquake there has been, in many parts of the island, a prolonged drought, the effects of which have been most disastrous. But in spite of these serious reverses, I see no reason to doubt that the energy of man, availing itself of the bounty of nature, will bring about in Jamaica a permanent prosperity, surpassing all that has gone before.

SUBSTITUTES FOR TIN.—The rise in price has also caused a search for a substitute for tin in the manufactures. The diminution in the price of aluminum, the practically limitless supply of raw material, and the physical properties of the metal are facts which must at once appeal to the technical imagination, and point to this—the most abundant of the metallic elements—as a possible substitute for tin. At the same time it is not the only metal which has to be considered in this connection. The world's annual production of tin is about 91,000 tons (long), and the principal uses to which the metal is applied are as follows: The manufacture of tin plates holding from 2 to 3% tin; the manufacture of machine bronzes and brasses, which in all probability accounts for the greater proportion of the world's consumption; the manufacture of various white alloys, such as solder, type metal, pewter, britannia metal, and white-bearing metals; ornamental bronzes and gold and silver-plated white metals; tin crystals, tin oxide, and the like.

SMEALTER PLANT AT KINGSTON.—In granting a site and exemption from taxation for 10 years to a lead manufacturing company of New York, and a local zinc company, the citizens of Kingston recently voted in favor of that course. The zinc company will erect buildings to cost \$100,000, and the lead company's buildings will cost \$40,000. The lead company is an American concern. Each company will employ 50 men. The Canadian Government will start at once to dredge a channel to the wharves to be constructed at the smelter sites, east of the city. The main supply of zinc ore to feed the proposed zinc smelter will be mined in the county of Frontenac. Zinc blende has been found at this mine, the ore being shipped to a New Jersey smelter heretofore. Other veins have been discovered in the northern portion of the county.

* This island, 150 miles long and less than 50 miles in average width, contains 4,000 miles of roads equal to our best.

Present Status of the Gold Mining Industry.

Written for the MINING AND SCIENTIFIC PRESS
By J. H. CURLE.

I suppose that this year the Transvaal will produce \$126,000,000 of gold, nearly all of it coming from the Rand conglomerate. The yield of this ore is now, roughly, about \$8 per ton. Even this low-grade average is only reached by considerable sorting on the surface, and by eliminating big patches of poor ore underground. These poor patches have become more frequent with depth, and engineers no longer sit at their desks and figure out the valuations of Rand mines by rule of three. There is not much profit earned by this big industry. As against an average yield of \$8, working costs may be placed at \$6. The balance is not all profit, for it has still

How can Rand working costs be lowered? Until recently the management has been extravagant, and there was no combined effort for improvement. Now, boards of directors have taken fright, and there is a general determination to exact greater all-round efficiency. It is realized that a cent per ton saved means \$150,000 per year profit, and that no channel of expenditure is too insignificant to be neglected. The directors will not greatly succeed in this. They are zealously cutting down all expenses and salaries—except their own. Their work, in these days, is mere routine, for which they are paid altogether too much, and until they voluntarily cut their fees in half, they will be able to impress neither manager, staff, nor miners that they are in earnest. I have not space here to discuss the question of Rand costs in detail, but will just say that the greatest room for improve-

General View of the Mysore Mines, India.

to be debited with redemption of capital; and on some of the shorter lived mines this item of capital redemption, if entered on the books, would more than wipe out the profit.

Owing to poor results from so many of the newer and deeper mines, the British public will not put up any more capital for further development; it has become disillusioned as regards the Rand. Any further financing of the industry, for years to come, must be carried out by the dozen or so big firms that control the mines. These people, of course, cannot put up all the capital asked for—over 100 million dollars—but they can at least carry out what they have guaranteed in this direction, and they have guaranteed to take up shares for 20 million dollars. If, because the share-market has since fallen heavily, they refuse to make good on these guarantees, the further development of the Rand will be greatly checked; the present number of stamps—some 8,000—will not be increased; the whole of the goldfield will be portioned off relative to the stamps already erected, and the shafts already sunk; and the ore, instead of being worked out at full pressure in 30 years, will last, at the present rate of exhaustion, for an indefinite period.

ment lies in the mining and handling underground, and especially in the work of the white miners. The Katlirs, if taken in hand seriously, and taught a sense of responsibility, are capable of better work. The suggestion of E. P. Rathbone, that big Katlir settlements should be established near Johannesburg, should be acted upon; there is money in teaching them to become more efficient miners.

The Chinese miners, introduced three years ago, have now become efficient, and though costing more than Katlirs, are found to give better value; besides, the reason for introducing them was because of the permanent shortage of Katlirs. On the subject of Chinese labor I agree entirely with the Rand directors. The Liberal party in England—in spite of the fact that this question concerns only the Transvaal and its inhabitants—has made a party-question of Chinese labor; and is trying to abolish it. Half these people believe that the Chinese are working in a state of slavery; the others believe that they are ousting an equal number of whites from employment. None of them, of course, know the facts. I know that in employing Chinese we are giving them better pay and more comfort than they would otherwise get;

that we are not keeping white men out of the billets the Chinese are filling; and that we are enormously assisting this industry by turning to this source of cheap and effective labor. I often see, even in American and Australian papers, statements that the Chinese took the place of white men. This is not true. These men receive, all included, less than \$1 per day, and no white man in the Transvaal can live on that sum. "Well," say the critics, "raise the scale of pay, and put in whites instead." This, of course, is a weak argument. I have already shown that the Rand is a low-grade field, and that on its ore, averaging an \$8 yield, there is only a small profit. Introduce all-white labor, at ruling rates, and the small profit would at once vanish and the mines close down. With the finest handling in the world the average Rand mill cannot employ all-white labor and earn a profit. To ignorant commentators let me point out that working costs are relative to conditions. In Australia, conditions usually admit of low costs, and ore yielding \$8 can be worked by white men at a good profit. In the Transvaal, as we see, \$8 ore yields a small profit worked by white and black labor mixed. In Nevada, \$8 ore is of no account to anyone—white or black. *Tout savoir est pardonner*, said the wise Frenchman. Finally, although unsound in its financial aspects, the Rand industry is of first-rate importance. In spite of over-capitalization, of poor patches, of loss of confidence, this field will continue to make an enormous production for many years. The gold of the Rand, placed in circulation, will prevent congestion of the world's banking facilities; and anything tending to limit or lower the production will tend equally to injure and restrict the world's trade.

Rhodesia, as a gold mining country, has been a failure. There is no lack of gold there, but it is not sufficiently concentrated for commercial mining. It is now realized that the average Rhodesian mine cannot support a capital of even £50,000, still less a board of directors, consulting engineer, and departmental staff. A number of small syndicates, whose members, assisted by the natives, run the mines themselves, are now at work in Rhodesia, and are earning profits where the companies could not. These syndicates mostly run five or ten stamps. Among some hundreds of gold mines floated on the company basis in Rhodesia, one alone, the Globe & Phoenix, has returned the actual cost put into it. Even this mine, at 1,000 ft., is looking shaky. Of the newer mines, the Giant promises to do well, as perhaps does the Penhalonga; but the financial aspect of gold mining in Rhodesia is not attractive.

Until this year I never believed that any of the West African gold mines were serious ventures. They were floated six years ago, and after the usual initial boom, passed almost out of memory. But I am satisfied that several of these mines have now merged from the development stage with valuable orebodies. Furthermore, it is now fairly well demonstrated that the climate, though bad, is not impossible, and that, as the result of this, a better class of men than formerly can be got to go out to the mines. The goldfield has now also got a railway from the coast, and working costs on the bigger mines are gradually reaching a normal figure.

The chief goldfield of West Africa is the conglomerate bed of Wassau, carrying an ore similar to that of the Rand. Most of this bed, traced and bored for some 20 miles, is evidently too low-grade to work, but there are spots where the gold is concentrated in well defined shoots. The ore-shoot of the Taquah & Abosso mine is unusually rich. A 50-head mill is just starting there, and according to the assay-plan, this should run on \$20 ore for the whole mine as exposed to the fifth level. This will be one of the biggest mills anywhere at work on such rich ore.

The Abosso mine is also well developed, and will average about \$15; a small mill has been running there for some months, and one 10% dividend has been paid. The Abbontiakoon Black and Wassau mines also contain ore-shoots of fair value, and should eventually earn profits.

Among the quartz lodes scattered over several West African fields, there has been the usual number of disappointments. Lenticular bodies, capricious in occurrence and in gold content, characterize most of these mines. One only, as yet, seems to have the makings of a big mine. This is the Prestea Block A. It is a strong vein, averaging 7 ft. wide, proved for some 1,500 ft. in length, and for 600 ft. in depth. All this will average about \$14, and for a quartz ore the gold occurs evenly throughout. There are now 50 stamps at work, to be increased to 100 when the railway reaches the mine. This property ought to have a future.

The last goldfield in Africa to be considered is that of Upper Egypt and Sudan—but I am afraid I cannot take it seriously. There is a little mine I inspected in Sudan called Um Nebardi, which will produce some gold, but I do not suppose it will return the capital sunk in it. As for the rest, they have not yet produced anything worth while.

Turning to America, the interesting features in the gold mining industry are the discoveries in Nevada and the dredging possibilities of Alaska and the Yukon. I believe in Nevada. I think it is the most wonderful mining country in the world. On the other hand the over-capitalization of these mines is terrible. I inspected a lot of mines at Tonopah, Goldfield, and Bullfrog, and tried to figure out some of these as having reserves relative to the price they were selling at. I found nothing. The public will lose heavily over Nevada, but this State will have a wonderful mining future.

Although actual figures are hard to get, it seems now to be realized that under certain conditions gold dredging in the frozen gravel of Alaska and the Yukon is a paying venture. The Guggenheim Exploration Co. is spending something like \$8,000,000 on a combined hydraulic and dredging scheme on the Klondike and in the season of 1906 good results were obtained from a dredge already in commission. I have mislaid the figures of this dredge's work, but it seemed to me, after digesting them, that dredging on the Klondike, allowing for a season of 120 days per year, and adding a liberal amount for depreciation, should not cost over 20c. per cu. yd., while the yield may average double that. There is one thing to be remembered: In these regions one cannot dredge away from his base, that is to say, away from a machine-shop, and the equipment and running of machine-shops in the Arctic, unless close to a transportation route, is hardly to be thought of. I believe that in certain cases dredging in these countries will pay well, but before risking money I should want to be dead sure on a good many points.

In Canada, as is usual, the gold mining outlook is disappointing, excepting the Klondike. There is really no goldfield in the Dominion worth taking note of. The reported discoveries north of Cobalt have not been confirmed.

In Mexico, the El Oro field still gives great hope. In the El Oro mine a new make of ore seems to be coming in at the 1,000-ft. level. This is sulphide, in which values have hitherto not existed. The adjoining Esperanza has used up its shipping ore, but the main lode is reported as still looking well in the bottom. Next to this is the Mexico, reported as having more net profit in sight than the price at which the mine is selling on the market. The biggest gold mine in Mexico I believe to be the Dos Estrellas, lying a mile distant from the El Oro vein. If this were properly developed and equipped, it

ought to do wonders; but its present shareholders do not understand these things.

In Central and South America there is not much gold mining. Dredging, as yet, has not made real progress. The dredging areas in Tierra del Fuego are shown to be of doubtful value, and the results from dredges in Matto Grosso are too small to be taken seriously.

In Australia there has been a steady falling off in the gold yield for several years, and no new mines of any value have come forward. The Kalgoorlie district in Western Australia is getting poorer in depth, but the ore exposed by the deepest workings, varying from 1,200 to 2,000 ft., is still of payable value. The mines are well handled, and half a dozen of them will have long lives yet. The scattered outside mines of Western Australia

rock. This is just unpayable. In this locality the river bed seems to be of unusual width. Were it narrower, and the gold concentrated, the result would no doubt be payable. In any case there must be rich patches, and if some of these can be found before the company comes to the end of its resources, the shareholders will gain more confidence, and see the thing through. Other mines of the group—notably Victorian Deep Leads and Berry United—seem to have better prospects than Loddon Valley, if boreholes indicate anything, but are not so far advanced with their pumping. If these deep lead mines are successful they will turn out a great deal of gold, and this is the only source of fresh supplies that I see at present for Australia. In New Zealand there is not much doing in gold. The Waibi, now proved to the

The Loddon Valley Deep Lead Mine, Australia.

are in a bad way. The only one of these which has not yet reached its zenith is the Lancefield—an orebody 18 ft. wide and 1,400 ft. long, worth \$8. Owing to the presence of arsenic in the sulphide ore a somewhat complex dry-crushing, roasting, and cyaniding plant is now being installed. The general manager, H. C. Hoover, claims for this a 90% extraction with total costs of \$5.50.

The older goldfields of Australia—Ballarat, Bendigo, Charters Towers, Gympie, Hillgrove, and such like—all seem to be slowly dying. They still produce materially, but I think the next five years will show a serious falling off. Dredging has been fairly successful in Victoria and New South Wales, but the areas are limited.

The most interesting development in Australia just now is the big pumping scheme to drain the Loddon Valley deep leads, on which Waldemar Lindgren reported favorably. In the Loddon Valley mine, equipped for a water output of 11,000,000 gallons daily, the wash was entered some months ago. The average gold content exposed up to the present is about \$8 per fathom of bed-

sth level, is still a phenomenal mine. With, I think, 320 stamps it is now yielding \$13 per ton, or over \$300,000 per month. Its reserves, according to the last report, were figured at a million tons.

In Asia, the few gold mines are widely scattered. The mines of the Kolar district in southern India are the biggest producers. This field turns out about 50,000 crude ounces per month. The Mysore mine works what is perhaps the most persistent ore-shoot known in any quartz mine. At 3,600 ft. on the incline this orebody is still strong and of high value. The yield of this mine, crushing 15,000 tons per month, is over \$20 per ton! The adjacent Champion Reef mine was equally good to below 2,000 ft. Since then it has fallen off; but arguing by the Mysore, which is on the same vein, one is not prepared to say that it is finished. The smaller mines of this field, some of which are on the main Mysore vein, do not promise to do much below 2,000 feet.

The gold mines of Malaya are not of much importance, I except from this the Redjang Lebong mine, in Sumatra,

which, under difficulties of climate and situation, is a large producer, and may be a persistently good mine.

On my last trip to the East, embracing Japan, Korea, and China, I came to the conclusion that that part of the world did not offer gold mining opportunities. Japan, of course, is practically closed to us. The Japanese keep their own mines, and are also exploiting some small gold mines in Formosa. They have annexed everything in Korea not covered by earlier concessions, and will no doubt be assisted by their Government to work anything good. The American concession in Korea, on which are the Oriental Consolidated Co.'s mines, is an interesting low-grade concern, but some of its mines were looking poor in depth. It was here I saw the Korean miner at work, and decided that for his pay he is the most efficient in the world.

In China there is gold, but nothing like so much as people think. Even in Manchuria there is no development on which one can base estimates. There is no gold mine with standard equipment, so far as I know, in the whole of China. The political outlook does not favor mining exploration in these Far Eastern countries.

Siberia, to my mind, is the richest gold mining country in the East. At the same time, economic conditions are unfavorable for vein mining there. I should not like to handle a quartz mine in Siberia, for I think there are problems connected with the winter climate that have not yet been solved elsewhere. British capital is now building a number of gold dredges in different parts of Siberia, and arguing by the analogy of Klondike, they may work out their salvation. However, I am sceptical; Siberia's turn will come some day, for quartz mining too, but under present conditions the utmost caution is needed.

In Europe the headquarters of gold mining are in Hungary and Russia, but there is no expansion. The best equipped mine is the Twelve Apostles, in Hungary, with 185 stamps and very fine electrical equipment. It is low-grade and does not earn much now. This is the only gold mine I know that is entirely owned and run by Germans.

IRON IN CUBA.—The greater portion of the iron ore imported into the United States comes from the province of Santiago de Cuba, in the southeastern portion of the island, the mines being owned and operated by American companies. Of the four companies which mined iron ore on this island, two—the Signa Iron Co., which operated in 1892 and 1893, and the Cuban Steel Ore Co., which was active in 1901 and 1902—have been abandoned. The Juragua Iron Co., the pioneer iron-ore operation, first shipped ore in the year 1881 and contributed, to the close of the year 1905, 4,238,683 long tons. The Spanish-American Iron Co., which made its initial shipments in 1895, supplied 3,022,283 long tons to the end of the year 1905. Iron-ore deposits also exist in other parts of the island of Cuba, a number of bodies of ore in the province of Puerto Principe being controlled by the Cuban Mining Company.

A CALIFORNIA JADE MINE.—The only jade mine in the United States is in the Klamath National Forest, Siskiyou county, California, where it was found last year. Samples of the jade were sent to Germany to be tested, and were pronounced to be of standard grade and capable of taking a high polish. Preparations are being made to develop the mine and ship the rock to Germany to be worked into ornaments. A permit for building a road to the mine has been secured from the Forest Service, which is especially charged with furthering in all possible ways the development of mines and all other National Forest resources.

The Prospector.

Enquiries sent to this department are answered free of charge, is submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

A piece of Specularite was received from J. S. of Bearmouth, Montana.

A specimen of Serpentine with galenite, pyrite, and chalcocopyrite was sent from Wallace, Ida., by J. J. M.

The three specimens of rock sent from Happy Camp, Cal., by M. L. G. are: No. 1, Gabbro; No. 2, Serpentine; No. 3, Serpentine.

The dike rocks sent by V. G. H., from Custer county, Colo., are: No. 1, altered Andesite; No. 2, rhyolite Porphyry; No. 3, Syenite.

A. J. N., of Radford, Yukon Territory, sends: No. 1, Quartz and Calcite carrying sphalerite, galenite, and chalcocopyrite; No. 2, altered Andesite; No. 3, fine-grained Marble.

Specimens marked W. from Goldfield are: No. 9, Quartz with horn silver; No. 10, Rhyolite; No. 11, mineralized andesite Porphyry; No. 12, mineralized Quartzite; No. 13, black Quartzite, No. 14, augite Andesite; No. 15, andradite Garnet; No. 16, Chalcedony; No. 17, iron-stained Quartz; No. 18, Andesite.

Rocks from A. P. B., of Luning, Nev., are: No. 1, Quartz, with garnets and pyrite; No. 2, Quartz, Andradite, Limonite, and Chlorite; No. 3, Quartz stained with iron; No. 4, Quartz stained with iron; No. 5, Quartz; No. 6, Quartz stained with limonite. No. 3 and 6 may be the gossam of a copper ore, and they might carry gold and silver.

THE DISCOVERER OF KLONDIKE.—Evidence has been gathered which shows fairly conclusively that to Robert Henderson, of Pictou, Nova Scotia, belongs the honor of being the discoverer of Klondike. In 1894 Henderson was outfitted at Ogilvie by his friend, Joseph Ladue. The summers of 1894 and 1895 he spent in prospecting the streams of the Indian River valley. During the winters of these years he mined alone on Quartz creek. In the summer of 1896 he discovered gold in Hunker Creek valley, or Gold Bottom, as he himself named the district. Provisions gave out in August, and Henderson was forced to go to Ogilvie for fresh supplies. On his way back to Gold Bottom, by the Klondike river, he spent a night on the present site of Dawson. It was here that he came upon Carmack. To Carmack, Henderson made known his discovery, and invited him to come up to Hunker creek and stake. Carmack followed in a few days, staked near Henderson's discovery and, returning, discovered gold in Bonanza creek. Of this discovery Carmack did not notify Henderson, but proceeded to Forty Mile, where he spread the news. At first his story was received with incredulity, but before long the stampede began, and the new finds were staked out before Henderson had been informed of their existence. Owing to complications, Henderson was refused a discovery claim on both Gold Bottom and Hunker branches of the river. He was, however, given the choice of staking one ordinary claim on either Gold Bottom, Hunker, or Bear creeks, or the equivalent of one out of five claims staked before others. Carmack's ingratitude lost to Henderson the chance of controlling the richest gold deposits of the North.—*The Canadian Mining Journal.*

Production of Copper.

The United States Geological Survey has issued a preliminary statement covering the production of copper in 1906. This has been prepared by L. C. Graton.

The production of copper in the United States in 1906 was 906,591,947 lb. This is an increase of about 18,000,000 lb. or 2% over the production of 1905 compiled on the same basis, and is a new record. The total is made up of Michigan's production of refined Lake copper and of the fine copper content of the production of blister. In the following table the production is apportioned to the States in which the copper was mined :

PRODUCTION OF COPPER IN THE UNITED STATES IN 1906.			
Lake Copper and Fine Copper Content of Blister.			
State.	Pounds fine.	State.	Pounds fine.
Alaska.....	8,685,616	New Mexico.....	7,099,812
Arizona.....	262,509,103	North Carolina.....	542,209
California.....	28,153,202	Oregon.....	545,859
Colorado.....	7,127,253	Tennessee.....	17,809,442
Georgia.....	17,182	Texas.....	51,377
Idaho.....	8,578,046	Utah.....	50,329,119
Massachusetts.....	9,744	Vermont.....	11,684
Michigan.....	229,685,730	Washington.....	230,821
Missouri.....	54,347	Wyoming.....	106,177
Montana.....	283,485,517	Total.....	906,591,947
Nevada.....	1,000,635		

Of this amount, 816,386 lb. in blister were produced in foreign smelters from materials exported from the United States. In addition to the total given, 51,543,116 lb. were produced as blister in domestic smelters from foreign ore, concentrate, and matte, while blister imported from foreign sources containing 136,826,906 lb. fine copper was electrolytically refined in this country.

The production of electrolytic copper in the United States in 1906, based on actual returns from all refineries was as follows :

	Pounds.
From materials of domestic origin.....	648,614,592
From materials of foreign origin.....	191,370,022
Total electrolytic copper.....	839,984,614

The figure for domestic production includes 24,017,833 lb. Lake copper which was refined electrolytically and an indeterminate but very small quantity recovered from scrap.

The production of domestic non-electrolytic copper refined by the furnace process and known as casting copper amounted in 1906 to 28,345,263 lb. This does not include Lake copper.

The total production of refined copper of domestic origin was :

	Pounds.
Lake (exclusive Lake electrolytic).....	205,608,382
Electrolytic, total domestic.....	648,614,592
Casting.....	28,345,263
Total refined.....	882,568,237

Complete returns show that the following stocks were on hand at the Lake and electrolytic refineries at the beginning and at the end of the year :

Date.	Pounds.
January 1, 1906.....	118,244,028
January 1, 1907.....	92,470,792
Stocks depleted during 1906.....	25,773,236

These figures do not include undelivered sales. Stocks carried by consumers have not been estimated. In addition to these stocks at refineries, there was at smelters or in transit to refineries blister copper to the amount of 110,000,144 lb. on January 1, 1906, and 100,630,215 lb. on January 1, 1907.

The apparent consumption of refined copper in the United States in 1906 was about 680,000,000 lb. as compared with about 600,000,000 lb. in 1905. One method of deriving this figure is shown herewith:

CONSUMPTION OF REFINED COPPER IN 1906.

Total domestic refined copper produced in 1906.....	882,568,237
Imports for consumption, foreign origin.....	215,402,841
Stock at refineries January 1, 1906.....	118,244,028
Total available supply.....	1,216,215,106
Exports.....	446,750,711
Stock at refineries January 1, 1907.....	92,470,792
Total withdrawn from supply.....	539,221,503
Apparent consumption.....	676,993,603

This is in addition to the quantity, perhaps as much as 50,000,000 lb., which was recovered from old copper, drosses, residues, etc., and re-entered the market, mostly in the form of casting copper.

Reduction of Quicksilver.

The extraction of quicksilver from its ores is generally effected by dry processes. The ore (generally cinnabar, accompanied at times by small globules of native metal) is decomposed by heat and liberated mercury is volatilized, to be later condensed and collected.

In the retort the decomposition is effected by the use of some reagent, such as lime or iron. Here the mercury vapor is kept entirely separate from the gases formed by the combustion of the fuel used in heating the retort. In the furnace, the sulphur in the heated ore is oxidized by the air to SO₂. In this method the furnace gases come into direct contact with the ore and pass into condensers with the mercury vapor, as CO, CO₂, N, unused air, SO₂, etc. The use of retorts is practically limited to the treatment of rich ores, mercurial soot, and concentrate. However, they may be used to advantage in treating small lots of ore, in making test runs, etc., and on this account, together with their small initial cost as compared with furnaces, they are generally adopted as a means of reduction in first opening up a new property and preliminary to the building of a furnace. In comparison with the furnace, the retort has a very small capacity and the expense for fuel and labor is much greater. Retorts are also short-lived, burning out rapidly even when great care is exercised in firing. However, they have the advantage of yielding the mercury vapor in a concentrated condition and undiluted by the furnace gases which prove so harmful in condensation of the quicksilver. The furnaces in general use in this country are of the shaft-type, and may be classed as 'coarse-ore' furnaces, and 'fine-ore' or 'tile' furnaces. Omitting differences in detail between various styles, the coarse-ore furnace consists of a cylindrical brick shaft into which the ore, mixed with the proper amount of coke, coal, or wood, is charged at the top and the ashes and spent ore are removed at the bottom. A pipe, issuing from the upper part of the furnace, carries the mercury vapor and hot gases to condensers. This type of furnace is unable to handle fine ore successfully, so before the advent of the fine-ore furnace the fine material was of necessity briquetted before treatment. At present the coarse-ore furnace has been almost entirely done away with, the general practice being to crush the coarse material to 1 or 2-in. size and treat it in the tile furnace. The fine-ore or tile furnace consists of a number of narrow rectangular shafts situated side by side, each provided with a series of inclined shelves or tiles placed in the opposite walls. These shelves slope downward at an angle of 15° and force the ore, which is fed at the top of the furnace, to follow a zigzag path to the bottom, where it is discharged. The end walls of the shafts are provided with openings, which allow the flames from the fire-box to pass through the ore on the shelves. The volatilized mercury, together with the furnace gases, passes into a vapor chamber and then on into the condensers.

Hints on the Design and Construction of
Wooden Trestles.

By R. BALFOUR.

*Heretofore the predominant idea appears to have been that a timber trestle is a structure of a very temporary nature, which does not require care in its design nor good workmanship in its erection; whereas, if the same care were used in calculating the strains and strength of materials in a wooden trestle as are applied in designing steel trestles, there would be quite a different attitude on the subject.

In providing for the conditions under which the timber has to do its work, the value of its actual working strength is almost an unknown quantity, owing to vary-

wet weather comes again and swells this out at right angles to the direction of the strains. This alternative shrinking and swelling in time destroys the fibre or strength of the wood. This oversight on the part of the designers is the primary cause of nearly all the failures of wooden trestles.

A secondary consideration should be the facilities for renewal, that is to say, the bridge should be designed with sufficient strength that every piece in each bent can be removed one at a time and another one substituted, without interrupting the traffic over the structure.

Fig. 1 and 2 are submitted as general plans for trestles up to or over 100 ft. high. According to this plan there are no stresses on the side wood great enough to destroy the fibre of the wood. It is so designed that it

Fig. 1. Suggested Design for Timber Trestle.

Fig. 2. Suggested Design for Timber Trestle.

ing atmospheric conditions. Particularly is this the case where the crushing strains come perpendicular to the grain of the wood. From personal observation, during an experience of 35 years, the writer has come to the conclusion that the safe working load, sidewise on hard pine, should be taken at 100 lb. per sq. in. in a moist climate, and varying in proportion to the dryness of the climate from that point to 200 lb. or even 250 lb. per sq. in. in very dry countries.

In actual practice it is more often strained 500 to 1,000 lb. per sq. in. During the wet weather the wood becomes soft and crushes together, and then afterward dries out, and in drying shrinks. The load coming on it holds it down to its smallest dimensions, and then the

can be removed piece by piece, and it is intended that all the timber in the structure shall be planed and painted. It is thought that its natural life should be from 25 to 40 years. The intention is to erect this bridge without being painted, but the precaution is taken to interpose a thin sheet of black iron between the intersection of any two pieces of wood throughout. It will be found that where unpainted black iron comes in contact with wood it is a preservative of the wood, and the oxidation of the iron answers the same purpose as an application of paint, so that when a structure is built of comparatively green timber, and thin black iron sheets are interposed between two members where they would otherwise come in contact, all the paint is supplied that is necessary at these particular points. Then after the timber has been seasoned in the work the exposed surfaces are painted.

*Abstracted by permission from the *Engineering News* of June 6, 1907.

It will be noticed in this plan that there is no direct sill or cap-sills. Instead of these, cross-wales are used, which are bolted and spiked on the sides of the posts at each 15 ft. in height, so that the load does not rest on the side wood. This holds at all places with the exception of the cap. Where the span is greater than 15 ft., the load on the cap will be too heavy to be taken up on the ends of the posts, as the posts would crush into the cap under the varying conditions of temperature, moisture, etc. To overcome this difficulty, cast steel corbel pieces are introduced on the head of the posts to give a greater bearing surface under the caps. Also on top of the cap where there are steel girders to span from bent to bent, a steel casting is used to distribute the load endwise along the cap.

Of course it will be necessary to have permanent four-

means the destruction of one of the parts that is fastened by the spike. Therefore the best solution is probably found by bolting the ends of sway-braces and cross-wales to the posts, and using a $\frac{1}{2}$ by 8-in. or 10-in. spike also at the ends, then spiking the other portions of these members to the posts. A large head on the spikes or perhaps, what is better still, a pressed washer on the head of the spike, is desirable.

Fig. 3 represents a general plan of a wooden trestle as usually built. This style of trestle has a batter of two inches to the foot (one in six). It has intermediate cap-sills and sill. Notwithstanding that this plan has the approval of two great corporations, it is faulty in many details. In the first place it has not sufficient spread to carry the great loads that are expected to go over it. The locomotives weighing over 100 tons and with a high

Fig. 3. Timber Trestle as Ordinarily Designed.

dations for a structure of this kind. If there is a concrete foundation, it might be well to have a cast or rolled steel plate imbedded in the upper portion of the concrete to receive the ends of the posts. If a stone masonry foundation is used, a good coping stone will be suitable to receive the posts by putting a thin sheet of rolled black iron between the posts and the stone.

There is room for a difference of opinion in regard to the fastenings for the different members. Screw-bolts are sometimes preferred on account of their adaptability for renewals; however, they do not necessarily prevent the initial movement of the structure, even if that movement is very small. And furthermore the safety of structures fastened with screw-bolts is entirely dependent on the care and watchfulness of the bridge repair gang. On the other hand, a spiked fastening effectually prevents initial movements, but in case of renewal of any portion of the structure the removal of a spike generally

centre of gravity, are expected to run over these structures at speeds of 50 miles per hour. The swaying or oscillation of the locomotives on a trestle 100 ft. high will be terrific, owing to the peculiar design of the structures. This swaying motion of the locomotive will have a tendency to crush the posts into the intermediate cap-sills and in a very short time, under high speed, the trestle will have to be renewed. The strains on the side wood of the sills and cap-sills will be sufficient to crush the life out of the wood between the upper and lower posts, owing to the shrinking and swelling of the cap-sills in wet and dry weather.

Because of the rapid increase in the cost of Oregon or Southern pine, or similar hard pines, and to the great increase in the rolling load, it is probable that the day of wooden stringers has already passed, if true economy is sought in the designing of trestles. Steel girders of from 30 to 100-ft. spans will be cheaper than the ordinary 12

to 15-ft. spans of wooden stringers, when we take into account the cost of the bents.

Fig. 1 shows a side view of the proposed bents in the writer's design up to 100 ft. in height. The sizes of the posts are to be 6 by 12 in., and the longitudinal wales (end view shown in Fig. 1, and shown in detail A) should be 8 by 10 in., and 32 ft. long. Where two pieces of the posts butt on to each other, two dowels $\frac{3}{4}$ by 4 in. are used (see detail A and B), and a piece of black sheet iron of about 24 B. W. gauge, cut 6 by 12 in. and inserted between the ends of the two pieces of posts. Detail C shows a corbel under the cap to which the posts are fastened, and also a cast-steel bed plate on which the steel girder rests. Of course there will have to be some means of fastening the steel girder to the bed plate, which is not shown in the detail.

Detail D shows a means of splicing the cross-wales when they become too long to be furnished in the complete length.

Fig. 2 shows a side view of a tower to carry steel girders with 9 by 12-in. stringers over the tower. The tower braces are to be 6 by 12 in. throughout until the tower exceeds 100 ft., and the longitudinal wales to be 8 by 10 in. The ties on this plan are shown 8 by 12 in., but if greater economy is desired the 9 by 18-in. stringers over the tower might be kept 4 in. higher and use 8 by 8-in. ties over the towers, always using the 8 by 12-in. ties over the steel girder.

TALC IN NEW YORK.—There is a large production of fibrous talc from New York, which amounts usually in quantity to nearly double the talc obtained from all the other States, and is nearly all used in the manufacture of paper. The New York talc deposits are situated to the east and southeast of Gouverneur. They lie in beds of tremolitic limestone, which run conformably with the hornblende gneisses and related schists of the region. They are included in a range about seven miles long and one mile wide, in which parallel belts are indicated by several occurrences. Beds of a workable thickness of 12 to 15 ft. are common, while at Talcville a workable thickness of 70 ft. has been found in places. The talc was formed by circulating waters carrying carbonic acid acting on beds of tremolite schist in the limestone. The tremolite thus became hydrated and lost its calcium, which was carried off in solution as the carbonate. The beds of tremolite schist would have formed by the metamorphism and recrystallization of a highly siliceous dolomitic limestone.

COLD SHORT is the term given to iron that will not stand working cold, bending, twisting, or punching very near the edges. Hot short is iron that will not work to good advantage while hot, but is strong when cold. Both kinds are suitable for their special purposes, but neutral iron is the kind to be relied upon for machinery. By neutral is meant iron that can be worked either hot or cold at ordinary temperatures. Good iron is often injured by being unskillfully worked. Care should be taken that the iron, while heating, is not exposed to the air. Iron heated for any purpose, especially for welding, should be heated as rapidly as possible, in order to expose it the least possible time to the action of the air and coal. For this purpose the strongest fuel is used with a strong blast. If in the operation of puddling the process be stopped at any particular time (determined by indications given by the metal to an experienced eye) in the furnace an iron is obtained of greater hardness and strength than ordinary iron, to which the name of semi-steel or puddled steel has been applied.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

The rule is that a mining licensee is without possessory right, and cannot maintain forcible entry and detainer or trespass, and, in short, is without any legal remedy whatever for injuries to the possession.

Continental Zinc Co. v. Amsden, (Mo.) 102 S. W. 1,087. June, '07.

A lease or conveyance of coal and other minerals with the right to mine the same for ninety-nine years, and a renewal in perpetuity, and by the terms of which the grantee was to render an account and pay royalties at specified rates when any coal or other mineral was mined, was held to contemplate a mining enterprise, and imposed on the grantee the obligation to make reasonable effort to operate such mines, and a failure to do so for more than twenty years amounted to a forfeiture by abandonment.

Brown v. Wilmore Coal Co., 153 Fed. 143. April, '07.

A coal and oil lease running for a long period of time, provided for a specified royalty, and that the operation of the mines should be begun and continued at the discretion of the lessee, and that no cessation of operation in mining should work a forfeiture; the lease was signed by the lessor only. In an action to forfeit the lease for failure to operate the mines, it was held that the lease was a mere unilateral contract, subject to cancellation at the instance of the lessor, and that the lessee having taken no steps to operate the mines thereunder for more than three years, could claim no rights by virtue of the lease.

Collins v. Abel, (Ala.) 44 Southern, 109. May, '07.

A right of action arises to the owner of the surface against the owner of the coal for injuries to the surface by the mining of coal when the support of the surface was so weakened that it might fall.

Tischler v. Penn. Coal Co., (Pa.), 66 Atlantic, 988. May, '07.

In an action to quiet title to certain mines where the defendant claimed that the plaintiff had abandoned such mines, it was held that a keeper was necessary and that his expenses were properly a part of the assessment work. But it was said that where a keeper was maintained simply to comply with the law relative to assessment work and to hold the property without any intent within a reasonable time to make use for the purpose of mining such structures as there may be thereon, and which he was employed to care for, then such expenditure should not be counted as assessment work. The expenditure, to count as assessment work, must be made in good faith, and it must reasonably be of personal use and benefit to the property as a mine by guarding valuable improvements made therein or thereon against deterioration or destruction, when such improvements may reasonably be said to be of value to the property as a mine.

Kinsley v. New Vulture Co., (Ariz.) 90 Pacific, 438, March, '07.

The lease of a mine provided that the lessee should leave sufficient pillars to support the roof, and for any breach of this condition the lease should be forfeited. The court decided that this stipulation was not a mere covenant, but a condition, the violation of which defeated the estate of the lessee, at the option of the lessor.

Greer v. Boston & C. Zinc Co., (Mo.) 103 S. W. 151, June, '07.

A lease of a mine provided that in certain event the lease should be forfeited at the option of the lessor and that notice of his option should be given by mail. In an action to forfeit the lease, it was held that notices sent by mail to the lessee at its place of business, followed immediately by a peaceable entry by the lessor was sufficient to terminate the tenancy.

Greer v. Boston & C. Zinc Co., (Mo.) 103 S. W., 151, June, '07.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

METHOD OF TREATING ORES.—No. 853,575; James W. Boileau, Denver, Colo., assignor of one-half to James B. Knoblock, Denver, Colorado.

The method of treating ores which consists in putting the copper in solution by subjecting the ore in a pulverized condition to the action of a solution of an acid, salt, and water in the presence of air under pressure.

CRUSHING-ROLLS.—No. 853,481; Frank P. Snow, Los Angeles, California.

In a device of the character described, a pair of crushing rolls, a housing therefor, a screen above the rolls within the housing, and horizontally disposed means independent of the screen interposed between said screen and rolls, said rolls being constructed to throw the crushed material, by centrifugal force, up past said interposed means and against said screen, said means being constructed to automatically return to the action of the rolls material not passed through said screen.

ORE CONCENTRATING AND SEPARATING MACHINE.—No. 859,483; John M. Callow, Salt Lake City, Utah, and James W. Neill, Butte, Montana.

In an ore concentrating and separating machine, the combination with the endless traveling belt and end rollers, of a deck or carrying plane arranged beneath the upper side of the belt for supporting the same, said belt being provided on its under side at one edge thereof with a continuous relatively broad projecting portion, said deck having a co-operating guiding groove, said end rollers also having a groove registering with the groove on said deck and co-operating therewith for guiding the belt in a longitudinal direction to prevent the belt from slipping sidewise.

ELEVATOR-BOOT BEARING.—No. 853,443; William R. Cunningham, Bucyrus, Ohio, assignor to the American Clay Machinery Co., Bucyrus, Ohio, a Corporation.

The combination with a casing and a shaft passing there-through, said casing having vertical slots or openings in which the shaft may be vertically adjusted, of housings exterior to the outer sides of the casing, journal-boxes or bearings in which the ends of said shaft are mounted, said boxes having closed outer ends and said housings being closed on their outer sides to form inclosed chambers in which the outer ends of the boxes are contained, said chambers forming vertical guides for the boxes, plates fixed to the boxes and extending parallel with the outer sides of the casing, and adapted to serve substantially as cover-plates for the slots of said casing to prevent material escaping there-through entering said boxes.

DEVICE FOR CHARGING FURNACES, GAS-GENERATORS, ETC.—No. 853,420; Hugo Rehmann, Mülheim-on-the Ruhr, Germany.

In a device for charging furnaces, gas-generators, and the like the combination of a hopper divided into three parts, and closable at the top, projections on the surface of the upper fixed part of the hopper, a crusher fixed on the rotatable middle part of the said hopper, projections on the surface of the crusher, means for moving the middle part of the hopper, means for periodically closing the lower fixed part of the hopper, and means for distributing the crushed coal at the outlet.

ROCK-DRILL CHUCK.—No. 856,877; Charles A. Hultquist, Lowell, Arizona.

A drill chuck having a socket to receive the drill shank, a key fitting a chamber upon one side of the shank, and adapted to be compressed upon the drill shank, bolts extending through the key and the chuck upon opposite sides of the drill shank, said bolts having cylindrical heads eccentric to the body portion, correspondingly shaped sunken chambers in the key and the chuck upon opposite sides adapted to receive the heads of the bolts and nuts.

Electrically Operated Hoist With Reels.

The accompanying illustration shows an electrically operated double-reel hoist driven through a double reduction of gears by an alternating current motor. The hoist is designed to handle a load consisting of 2,000 lb. ore in a skip weighing 2,000 lb. from a depth of 1,200 ft. at a speed of 500 ft. per min., the up-coming load being balanced by the down-going skip.

The hoist is supported on a cast-iron bed-plate of the inverted U type, hollow in section, and surrounding the entire machine. The reel-shaft rests in two large adjustable babbitted bearings and is designed to carry the maximum load without undue deflection. Each reel has a capacity of 1,200 ft. of $3\frac{1}{2}$ by $\frac{3}{4}$ -in. rope, and is fitted with a friction-clutch and post-brake. The reel-hubs are lined with bronze removable bushings which have a projected area giving a pressure of not over 80 lb. per sq. in. for the maximum load to which each is subjected. The friction-clutches are of the well known Webster, Camp & Lane type, which up to the present, is the most successful clutch made for mine-hoists. They are especially designed for

Electrical Hoist With Reels.

heavy work, have few parts, are easily adjusted and require few repairs. They enable the operator to change levels with the least loss of time. The post-brakes are built up of steel plates and angles, and are provided top and bottom with suitable adjustments. The brakes are lined with basswood blocks, which, under the maximum loads, are subject to a pressure not exceeding 20 lb. per sq. in. The clutches and brakes are operated by hand levers, conveniently arranged at the front of the hoist. The hoist is fitted with a safety device, operated from the indicator, so arranged that if the skips are hoisted beyond a pre-determined point the brakes are automatically applied. Each reel is fitted with an indicator driven from the reel hub by heavy bicycle chain and sprockets with cut teeth. All the gears on the hoist have cut teeth of the short involute type. The electrical equipment consists of a General Electric, type I, 10-pole, 60-hp., 600-r.p.m., 1,040-volt, 50-cycle, 3-phase motor, having a full load of efficiency of 86%. The full load torque of the motor is 525 lb. at one-foot radius, and the maximum torque is approximately 2½ times that amount. The insulation is tested to withstand 3,000 volts alternating current for one minute, and the temperature will not exceed 40° C. at rated capacity after 24-hr. run. The controller is provided with primary contacts, operating in oil, contained in the main controller cylinder. There are six running points, enabling the operator to run the hoist at several speeds continuously.

The resistances are of the standard iron grid type, the grids being assembled on skeleton frames and are air-cooled. They are designed for balanced hoisting only. This hoist is one of 12 reel hoists of various sizes for the mines of the Compañía de Real del Monte at Pachuca, in Mexico; it was designed and built by the Wellman-Seaver-Morgan Co., of Cleveland, Ohio.

Books Received.

'Specifications for Street Roadway Pavements,' by S. Whinery. The Engineering News Publishing Co. Price, \$0.50, net.

'Commercial Organic Analysis,' by Alfred H. Allen, Vol. II—Part III. A well-arranged treatise on the properties, modes of assaying, and proximate analytical examination of the various organic chemicals and products employed in the arts, manufactures, and medicine, with the methods of detection and determination of their impurities, adulterations, and products of decomposition. P. Blackiston's Son & Co., Philadelphia. Price \$5.

'Gold Dredging,' by Capt. C. C. Longridge. Second edition; 325 pages. Price, \$6.50. The Mining Journal, London. Also for sale by the MINING AND SCIENTIFIC PRESS. This is an enlarged and revised edition of a volume, containing much valuable information in regard to dredging in West Africa, Australia, New Zealand, and other countries. It is largely a compilation, useful to those who want the information scattered through the technical papers and

the bulletins of the U. S. Geological Survey. The book is handsomely illustrated, it contains numerous drawings, and details of cost. Much prominence is given to manufacturers of dredging machinery and the advertisement of various engineering firms is a feature of the illustrations, but as this affords information to those engaged in the industry, it is a feature that may be pardoned by the purchaser, who will find himself in possession of a valuable compendium.

Catalogues Received.

The Ingersoll-Rand Co. has published Bulletin No. 2,010 on 'Crown Pneumatic Hammers,' and labor-saving devices operated by compressed air.

THE SULLIVAN MACHINERY Co. of Chicago, has issued Bulletin 56, on Sullivan Mining Hoists. This is an attractive little publication, containing cuts of some of the larger hoists installed by this company.

F. W. BRAUN has just issued Catalogue R, containing 450 pages describing the assayers and chemical laboratory apparatus and supplies, fine chemicals and reagents. The new quarters of the company are at 409 East Third St., Los Angeles, and 576 Mission St., San Francisco.

MOORE FILTER.—The three years' litigation involving the well known Moore Filter patents for treating slime has come to an end (as indicated in the advertisement to be found at the top of page 4 of this issue) with the result that all the rights, titles, interests, and claims now rest with the Moore Filter Co., whose New York office is at 40 Pine St. They are represented in the West by J. V. N. Dorr, 204 Bank Bldg., Denver.

Editorial.

BETWEEN the United States and her noncontiguous territories there is a trade amounting, in 1907, to \$67,250,586 of exports and \$74,807,690 of imports, exclusive of the \$18,583,702 worth of gold shipped into the United States from Alaska. That northern territory took nearly \$1,000,000 worth of iron and steel manufactures, chiefly machinery, in 1907. The imports are three times and the exports six times as much as they were ten years ago. Manifestly Alaska, Hawaii, Porto Rico, and the Philippine Islands afford openings for a further expansion of trade.

IT HAS BEEN SUGGESTED to us that the American Institute of Mining Engineers should hold one of its proximate sessions on the edge of the Grand Canyon, in Arizona. There are two excellent hotels affording all the necessary accommodations for 500 people and there is a room large enough for meetings. The geological interest of the Grand Canyon and the splendor of the scenery need not be emphasized. There are no large mines or smelters in the vicinity, but it is not far to Jerome or Prescott. A series of lively sessions, with well sustained discussions, might be better than much sight-seeing.

THE METAL MARKETS are dull, because there is a great disinclination on the part of buyers to operate, and in consequence stocks are accumulating in the hands of producers. While during the time of the depression, reports from the West were encouraging in a general way, so far this has not affected the metal industry; on the contrary. The iron and steel business, which had kept up at full steam until a few weeks ago, is now also showing some signs of falling off. In copper the market is entirely nominal, with only a small retail business doing. While the larger producers are nominally holding for a price of 22 cents for electrolytic, there are sellers below 21 cents without finding buyers. In lead, consumption appears to have fallen off materially of late, and stocks have accumulated in the West as well as in the Eastern refineries. This accounts for the break in prices from 6 to 5.25 cents. Of late, however, there is slightly more demand, but, as far as we can see, only enough to take care of present production, not of the accumulation. Spelter has been declining very heavily, and is now quoted at 5.75 to 5.80 cents. Manufacturers are loath to commit themselves by contracting ahead.

ON ANOTHER PAGE we publish a useful article describing the sinking of a shaft in bad ground. It was prepared by an engineer, Mr. F. W. Adgate, on the staff of the company responsible for the work, namely, the Foundation Company, which makes a

specialty of such engineering contracts. This article, or portions of it, may have appeared in other journals, but without giving the name of the author or his connection with the company whose operations he describes. The matter is of interest as bringing up the general question of the relation between the editor and the advertiser. Our own policy is simple. We believe that it is our duty to give our readers the best technical information obtainable, and when it comes from persons associated with advertisers, it is only right to say so. Not that the information is necessarily vitiated by coming from one who is connected with the enterprise described, but as an evidence of good faith. Obviously an article signed by a member of the profession is worth more than the unsigned descriptive matter issued by the publicity bureaus of manufacturers.

IF THAT \$29,000,000 is collected from the Standard Oil Company, it is suggested that it might be used to build battleships, to be christened after the men at the head of the monopoly. What a piratical squadron it would be. The Jolly Roger might represent H. H. Rogers, the John D. and the Arch Bold would be dangerous, and the Harriman certainly would never be afraid of water, even far from Wall Street. Their ensign would be a hymnbook from a Cleveland Sunday school, a ticker upon a yellow field rampant, with the motto underneath: "The public be damned."

NEWSPAPERS publish many things that are palpably foolish and it is curious how some that are obviously incorrect go the whole round of the press without eliciting correction. A weird yarn has outcropped in many of our exchanges and appears now in the scrap-heap of *Tit Bits*, to the effect that Mr. John Hays Hammond gets the largest professional income in the world and that he possesses "such infallible knowledge of the value of gold-bearing ore that he can pass unerring judgment upon mines without visiting them." As to the salary, that is an affair into which it would be impolite to inquire, for it is none of our business. But as to this appraisal of mines at long distance it is fair to Mr. Hammond himself to deny such an absurdity, in fact, we would call it a libelous misrepresentation calculated to injure the position of an engineer in so high repute. It is worthy of mention because there may be younger men desirous of emulating such a method of mine inspection and it may be that there are professors so academic as to lecture approvingly on this new method. But it won't do. To examine mines means hard work on the ground, personal attention to details, and an intimate acquaintance with working conditions, as Mr. Hammond knows better than most of us. Moreover even if enthusiastic youngsters and thoughtful professors are not misled by this suggestion of short cuts to big fees, it is likely that the pseudo-expert, who is always with us, will adopt the method as convenient and remunerative. Think of the well known Col. Boomfixer at New York or the eminent Mr. Thomas Spoof N. Y. Z., etc., at London being able, on account of their eminence and scientific attainments, to polish off reports at short notice

on the Great Wildcat Unlimited or the Hot Bullion Consolidated without even getting on a train, without the weariness of a long journey, the hardships of beans and bacon, the exposure to thirst in Esmeralda county, or the lack of stimulating society in Siberia. We grieve that the public should be endangered by the suggestion of a new device for making money easily and of a scheme calculated to destroy the usefulness of those engineers who by hard work and study of local conditions have equipped themselves for the giving of professional advice. But it is not true. We venture to say so without referring the matter to Mr. Hammond. It is a sad joke. Once more, it is apparent that when you see it in the daily press, you can be sure it is not so.

Pioche.

PROMINENCE is given in this issue to an article on Pioche by Mr. James W. Abbott. The revival at Pioche is another manifestation of the renaissance of Nevada, and it is due to the construction of a branch railroad, an enterprise stimulated in turn by the increasing interest taken in the mining regions of the Great Basin—that vast tract of arid treasure-land that stretches from the Rockies to the Sierras. We wish good luck to Pioche; may she rise strengthened from the slumber of the years and come forth vigorous with renewed youth to assert her place among the mining camps of Nevada. Mr. Abbott tells the story of other days and the hopes of these. He mentions names well known to the veterans of the profession. The Charles E. Hoffman of Pioche's beginning died a few weeks ago in Mexico. He lived at San José and was formerly connected with the mines of New Almaden. Although a noted mining man, this Hoffman must not be confused with Charles F. Hoffmann, of Oakland, the mining engineer who is father of a family of capable technical experts now scattered from Dawson to Johannesburg. Then there is a reference to Alexis Janin. He died in 1897. The three Janius—Louis, Henry, and Alexis—were notable men in the early mining history of the Pacific Coast and two of them survive happily today. Mr. Henry Janin is at London, no longer in practice, but still in touch with the profession. He made the first expert report on the Meadow Valley mine. Mr. Louis Janin is one of the trustees of the State Mining Bureau and gives younger men the benefit of his ripe experience. He spends a large part of his time on a farm in southern California. The assayer at Pioche in 1868 was Gardner F. Williams, until lately the general manager of the De Beers Consolidated mines at Kimberley, another Californian who has proved the value of an early environment of mines and mills. C. A. Stetefeldt died in 1896. His process held a large place in Western metallurgical literature twenty years ago, but it was not widely applied, being adapted to a restricted class of ore. It stimulated research and had a theoretical value greater than its commercial application. Processes come and go, mines have their day, but mining goes on increasing in importance and complexity. Thus, long after Brigham Young has passed

away in a mist of tradition, long after the old silver mills have become obsolete, the stage coaches of Gilmer & Salisbury are replaced by the reckless automobile, and the mule train is succeeded by the vestibuled Pullman. After a long wait, Pioche has come to her own again. More power to her.

That \$29,240,000 Fine.

A FEDERAL JUDGE in Illinois has imposed fines aggregating \$29,240,000 upon the Standard Oil Company, for violation of the Interstate Commerce Law in accepting rebates on freight due for the transport of oil. The amount looms large in the public eye and it is said that the decision of the Court will be contested on the ground that it is a "cruel and unusual punishment" contrary to the Constitution of the United States. But the judgment is not likely to be upset on this score, for the constitutional provision referred to was designed to guard against torture and inhuman methods of execution, and not cumulative sentences. Undoubtedly the moral effect of the sentence would have been as great if the minimum fine — \$1,000 for each of the 1,100 infractions of the law — had been levied. For it is improbable that the persons responsible for the wrongdoing will be punished. The Standard Oil Company has only to increase the price of its product in order to make the public pay the \$29,240,000 to the Government. This illustrates the difficulty of disciplining a monopoly. The individuals responsible are not reached by such a sentence. The corporation itself is a legal fiction. The Standard Oil Company is controlled by a group of daring financiers, although the majority of its stockholders are small investors innocent of wrongdoing. Those responsible for the rebates will escape. Similarly, the Chicago & Alton Railroad, which gave rebates to the oil company whereby its freight rate of 18 cents was reduced to 6 cents per hundred pounds, is largely the property of small investors. The company is to be indicted, and is likely to be mulcted for infractions of the law. Is a further tax to be put upon the shareholders and bondholders of the railroad that Mr. Harriman has almost wrecked by his unscrupulous dealings? Is the trust fund to pay for the maladministration of the trustee? Having been used by Harriman as a means of making concessions to the pirates of the Standard Oil, must the railroad investors suffer further from the illegal acts of their officers? We trust—and we speak feelingly as a bondholder in a small way—that the effort to assert the law will lead to the punishment of the individuals who are responsible and that the innocent investors no less than the community at large may be protected against men who under the guise of trustees for shareholders are playing their own high-handed game.

We have heard much of the trial at Boise lately and the leaders of a union have been held up as anarchists. We regard H. H. Rogers, John D. Rockefeller, and E. H. Harriman as in effect no less anarchists than Emma Goldman, W. D. Haywood, and Clarence Darrow. The

last three do in a rough brutal way what the first three accomplish in a polished skillful manner. One group undermines, the other over-rides, the law. The \$29,240,000 looks big, but it is only a small part of the money filched from the people of this country by a corporation that exists by permission of the law and under the protection of it. If the fine is legal, we hope to see it collected; if not, if it is set aside by a higher court, we hope new laws may be passed whereby larceny *in excelsis* will be checked.

Once more it is impressed upon us that the natural man is predatory, and this brute instinct is evinced most strongly by the substratum and super-stratum of humanity. It is only the code that saves the community from destruction. Men must be bound by the iron bands of law, otherwise they make depredations unceasingly. It was thought that corporations could be controlled through their organization. This has proved a delusion, for they only act through their agents. It becomes necessary to make those agents liable under the criminal statutes. Existing legislation appears to be inadequate, but if public opinion asserts itself there will be a demand for punitive enactments to bridge an existing hiatus. Economic conditions are progressive in their development, and they demand new laws for new crimes. The motive power for such action must come from an enlightened public opinion, without which the law is a dead letter. Meanwhile let us recognize the foes of popular government in the men that deliberately use legal methods to thwart the law. Bracket Rockefeller with Emma Goldman, and Harriman with Haywood. Anarchy is utter disregard for government; the definition fits the case.

WILD-CAT AND HIGH-GRADING are terms that have been accepted in the language of mining. The first is not new, it is probably forty years old, having originated in connection with reckless banking just before the civil war when one particular bank, organized under loose State laws, became notorious. On the notes of this bank there was the figure of a wild-cat or *felis catus*. It became a synonym for reckless promotion. In Australia, as is well known, rabbits are a pest, except in Western Australia, where they do not exist. The desert has served as a barrier. During the boom days ten years ago it used to be said that the West Australian wild-cats had prevented the rabbits from invading the country from the Eastern colonies. From 'wild-cat' we have obtained 'wild-catter,' a dealer in feline finance. The other term, 'high-grading,' originated we believe at Cripple Creek. It refers to the stealing of rich ore. At Goldfield and Cobalt it has become a familiar word, and indicates the prevalence of a form of petty larceny most demoralizing to honest work. Both 'wild-cattling' and 'high-grading' refer to criminal offences and it is curious how such slang terms by their false suggestion of humor are calculated to glose the essential wrong of the acts they describe. 'Graft' seems a humorous variation of 'theft.' Wild-cats are swindlers, high-graders are sneak thieves.

Personal.

S. F. EMMONS is at Cananea.

WALDEMAR LINDGREN is at Denver.

POPE YEATMAN has returned to New York.

J. R. FINLAY is in Custer county, Colorado.

D. A. LOUIS has returned to London from Egypt.

MARK R. LAMB is at Porters Hotel, Mexico City.

W. H. ARGALL is on his way from London to Uruguay.

J. P. WALLACE, lately at Laredo, Texas, is now at Goldfield.

J. P. HUTCHINS sailed from Seattle for Nome, on August 5.

FREDERIC J. SIEBERT will be at Goldfield for several months.

CHARLES B. LEWIS, of Nacozari, Sonora, is at Los Angeles.

HOWARD D. SMITH has gone to Los Angeles, on his way to Mexico.

MARTIN SCHWERIN has made a report on the Buffalo mine at Cobalt.

S. H. BROCKUNIER, of New York, is in California, examining clay deposits.

G. W. MILLER, of Denver, is examining mines near Pocatello, in Idaho.

DEANE P. MITCHELL is manager for the Zinc Corporation at Broken Hill.

WILLIAM BAYLEY SR., of the Gold Roads Mines Co., in Arizona, is in Europe.

TOM R. JONES is superintendent for the Buffalo Mines Ltd. at Cobalt, Ontario.

J. P. GAZZAM was in San Francisco this week and has gone to Jamestown, R. I.

C. D. WHITE, who is mining near Trinity Centre, was recently in San Francisco.

ARTHUR GOODALL, manager for the Fremont Con. Mining Co., in Amador, is here.

W. J. LORING is general manager in Australia for Bewick, Moreing & Company.

R. H. BURROWS has returned to Guanajuato after a long journey in eastern Chihuahua.

JAMES W. NEILL is directing the construction of a dredge on the Merced river, California.

WILLIAM WARR, engineer for the Blaisdell Co., has returned from Mexico to Los Angeles.

C. W. ROBBINS, of Custer, South Dakota, is superintendent of a mine near Del Norte, Colorado.

F. L. BOSQUI has been appointed metallurgical engineer for the Goldfield Consolidated Mines Company.

EDWARD SKEWES has returned to Huddersfield, England, from the inspection of mines in Hungary.

DAVID GOODALE, manager for the Rio Tinto Mining Co., at Chihuahua, sailed for Honolulu on August 8.

FRANK ROBBINS is at Ensenada in Lower California; he expects to return to Los Angeles about August 20.

S. R. PORTER, superintendent for the Gold Roads Mining & Exploration Co. of Arizona, is at Los Angeles.

LOUIS WEBB, formerly at Cambridge, Mass., and now at Montagu, in Shasta county, California, visited San Francisco.

H. B. BARLING, lately in Ventura county, is now superintendent of the Yellow Rose mine, in Trinity county, California.

E. A. H. TAVS is at Butte, after a journey to Nova Scotia. He intends to make permanent headquarters at Denver.

C. W. MERRILL, metallurgist to the Homestake Mining Co., was not on the ill-fated *Columbia*. That was another man with the same initials. Mr. Merrill has returned to Lead, South Dakota, after a visit to California.

General Mining News.

ARIZONA.

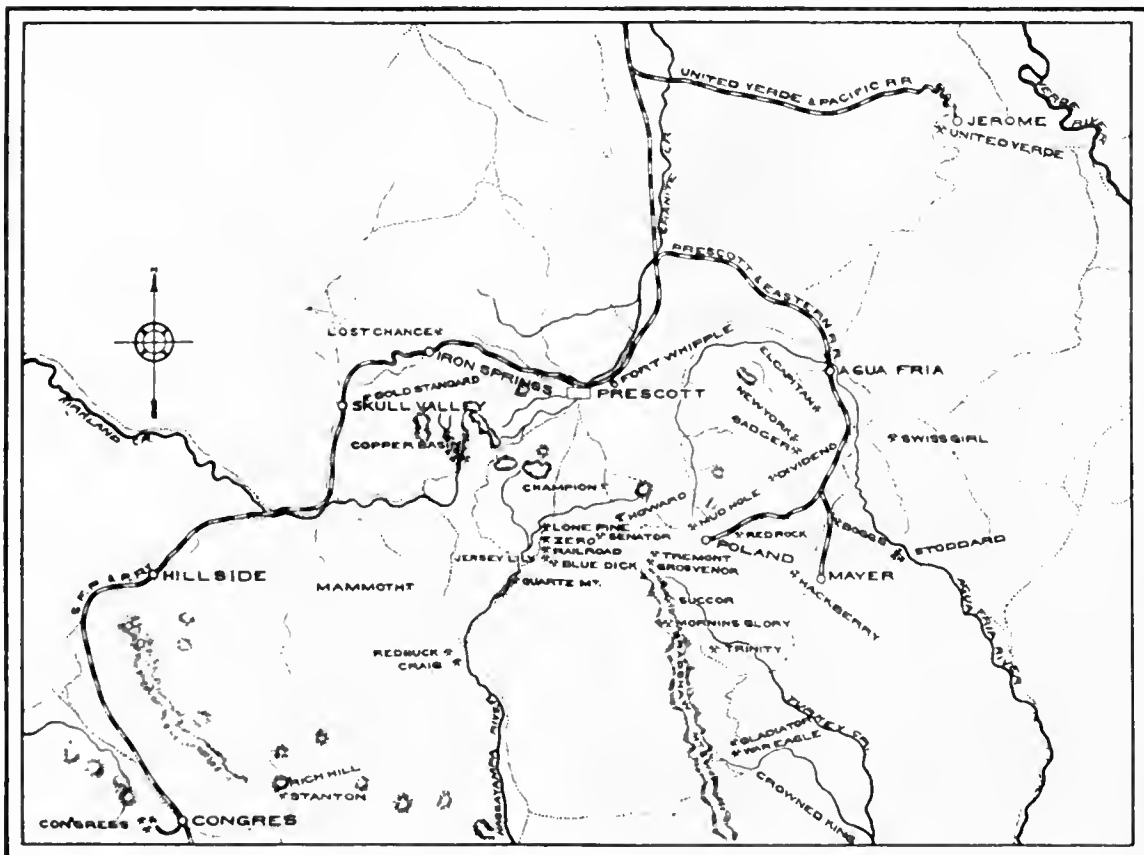

COCHISE COUNTY.

The spur of the E. P. & S. railroad to the Denn shaft will soon be completed, and the ore-bins will be erected at once. Sinking is being done in the shaft, and it is down 1,175 ft. The drift on the 1,100-ft. level is encountering softer ground and more water, and the drift on the 1,000-ft. level is being extended. Shipments will probably start about September 1.—A full force of miners is employed at the Shattuck-Arizona, and 300 tons of ore per day is mined. The new compressor building is nearly finished. The drift on the 900-ft. level continues in low-grade ore, and development continues on the 700 and 800 levels.—The shaft on the Warren R. & D. Co.'s ground is down 285 ft.—The buildings for the machine-shops of the Calumet & Arizona will

to water-level before any driving is done, which will probably be at about the 400-ft. point. W. N. Clute is the manager.—Perhaps the largest work under way in the entire Bisbee district is the power-plant being erected by the Copper Queen company on a site between the Gardner and Sacramento shafts. It is their plan to furnish with this plant all air, steam and electricity consumed in their mines. The foundations are already in and the work of putting up the steel frame of the building will begin shortly.

YAVAPAI COUNTY.

A payment of \$28,000 will be made to the former owners of the Monica group of mines, in the Kirkland district, by the Monica Mines Syndicate, as an installment on the purchase price. This makes \$73,000 in all paid to date.—Four miles north of Crown King, in a shaft immediately south of the Bradshaw Mtn. railroad track, what appears to be one of the most promising strikes recently made in the Bradshaw mountains, was uncovered a few days ago on the

Map of a Part of Arizona.

be finished in two months. At Douglas the new power-house will soon be finished.—A large block of leached ground has been opened on the 1,000-ft. level from the Biggs shaft in the Superior & Pittsburg; the shaft is being sunk toward the 1,100-ft. point, where a drift will be started. The new Prescott pumps are being installed on the 1,100-ft. level in the Junction shaft. Some ore has been opened by the lower levels from the Hoatson shaft, but has not been much developed.—The C. & A. company has purchased the Leadville properties in Turquoise district in the Dragoon Mtn., and John Talbot will be in charge of the work there.—A new wood-lined pump has been put in at the Holbrook shaft of the Copper Queen, to withstand the corroding action of the acid water. The Czar shaft is being enlarged to make room for the pump columns.—The Cochise Development Co. is sinking its shaft, and a new gasoline hoist has been erected at the shaft of the North Bisbee D. Co.—It is reported that the Verde Green Copper Co., composed of Minnesota shareholders and operating 15 miles west of Benson, has cut into a body of lead carbonate ore. Ore is being hauled 12 miles to Patana, whence it is shipped to the Luna smelter at Deming.—The shaft of the Bisbee Extension company is down 345 ft. and is altered limestone, with some iron and copper stains. The shaft will be sunk

properties of the DeKalb Mining Co. At a depth of 30 ft. in the shaft a pay-streak was struck sampling 106 oz. silver and 58% lead. The find was made in a vein running in a northeasterly and southwesterly direction through a schist belt about 200 ft. wide, which cuts through the granite formation.—Recently a deal was perfected by which the Mountain View group of mines, in the Turkey Creek district, passed from F. A. Bletcher to the Liberty Mines Co., a corporation organized by local capitalists. In a short time a force of men will be started sinking one of the shafts in which there is an excellent showing of lead-silver ore. There is a plentiful supply of water on the ground for camp and other purposes and the group is within easy reach of the Prescott and Crown King wagon road.

Newton Evans, general manager of the Signal Copper Co., owning the Copper Prince group of mines in the Bill Williams Fork district, has gone to New York to complete the sale of the property to Eastern copper interests.—J. P. Moffett and Perry O. Spittler returned from the Thumb-Butte Co.'s mines, 18 miles northwest of Castle Dome, and report a new strike of silver and copper glance near the surface.

A deal is pending in the Patagonia mining district that will involve about 100 gold and copper mining claims, many

of which have been opened, and a few have operating plants and machinery on them. Aside from the mining claims, the deal, it is said, will include the Patagonia town-site.—A gold strike has been made north of Palomas by J. Fred Nottbusch. A shaft has been sunk 10 ft. and the ore in it assays \$12.40. Location work on five claims is in progress.—There is a rumor that the people who have the Mayhew Strike under bond will soon pay the amount due on the property and come into full ownership. The amount agreed upon was \$350,000, and the first payment was \$12,000. The men who bonded it lost no time in development, and recently ore was struck in the North Star claim, in a new shaft.

CALIFORNIA.

KERN COUNTY.

(Special Correspondence).—A strike of considerable importance has been made on the ridge north of Indian creek, in the Amalie district. This ridge runs east and west, and along its apex is a massive outcrop of quartz and quartzite, in which are found mineralized veins and stringers of varying widths, rich in silver sulphide and antimonide. These veins occur both parallel and at right angles to the outcrop. Several samples taken across them assayed about 40 oz. silver, some of them running as high as 300 oz. The property is being opened up by the locators, who are getting shipping ore from near the surface.

NAPA COUNTY.

The La Joya mine, near Oakville, a property that has not received much attention in the past, has recently been opened up and drift has encountered high-grade cinnabar ore, lying just above a black alta and beneath an altered serpentine. The development has thus far been done by tunnels, but a winze will be sunk near the end of a 1,400-ft. tunnel in search of ore beneath the black alta. If satisfactory results are obtained by this winze a long adit will be run at a lower level.

NEVADA COUNTY.

Good progress is being made in the tunnel at the Fairview mine, above Relief hill. The tunnel is in 500 ft. and will have to go 400 more before the vein will be cut.—The company that is opening up the Giant King mine, near Washington, is building a sawmill near Phelps hill.—The organization that has been working the Austin quartz mine in Willow valley, has been incorporated under the name of the Nevada County U. G. M. Co., with a capitalization of \$500,000. The directors are H. A. Moss, Lathrop B. Bullene, W. W. Rose, F. E. Ware, and W. S. Beard.

PLACER COUNTY.

The old Homestake quartz mine, near Forest Hill, has been opened up again.—The Crater shaft is being unwatered.—It is reported that the old Hazard mine, in Volcano, may be worked again.—Work on the Southern Cross has been resumed under the charge of R. J. Trimble.—A contract for sinking 100 ft. at the Bellevue has been let.—Drifts are being run from the 200-ft. point in the shaft of the Gold Blossom mine. The one toward the east is in 250 ft.—Work is progressing on the Imperial. The old mill has been taken from Pat Goggin's mine to Big Oak Flat, and will be set up there. Wm. Duffey is the superintendent.—J. T. Gavin has finished the tunnel on the Ceanothus mine, adjoining the Mayflower, and has struck the gravel channel. The channel has been opened for 100 ft., and the gravel at the head of the new tunnel prospects well.—The old Mamaluke mine, on Georgia hill, is being prospected again. In the new tunnel at the Eureka 15 men are employed, under J. A. Ferguson.—Several of the officials of the Northern California Gold Mines Co. have recently visited the Herman mine.—About 20 men are at work on the old Bonanza mine at Gold Run, owned by the Gold Run Gravel M. Co., of which J. D. Stewart is the superintendent. The company has practically rebuilt the 10-stamp mill, and 30 stamps will be added. A new compressor has been erected, and the mill will be run by water power, the water coming from the Yuba river, through the Miners' ditch. The company plans to work the cement gravel that was left when the loose overburden was hydraulicked off. The working tunnel is in 2,000 feet.

SAN BERNARDINO COUNTY.

The Victor Gold M. Co. has four 175-hp. boilers in place in its new power plant at Needles, and the 700-hp. steam engine will drive an electric generator. The new 120-ton mill is nearly finished and the hoist is in place. The tubemill and cyaniding equipment have arrived, and the pump to furnish 240,000 gal. water is at Kingman. The company claims to have about 100,000 tons of ore developed that will average \$20 per ton.—The Gold Road company is also planning to erect a power plant at Kingman, and transmit electrical power to its mines.

SIESTA COUNTY.

The new machine-shop of the Mammoth Copper Co. is 400 ft. long and equipped with a traveling crane. The grading is finished for the new 250-ft. stack, and the powerhouse is being enlarged. At the mine, the big tunnel has been started. This will be 18 ft. wide, to accommodate a double track for electric haulage from the ore-chutes to the gravity train.—H. H. McClure, of Bully Hill, has sold three placer claims on Squaw creek to George T. Slaughter of Delamar.

SIERRA COUNTY.

A crew of 30 men is employed at the Sovereign mine in making surface improvements. The new ditch and road have been completed, the ditch for power purposes having a capacity of 1,000 miner's inches under a head of 230 ft. A lower tunnel is being run that will tap the vein 460 ft. deep, and grading is being done for a 20-stamp mill. Horace Morse is superintendent and George F. Taylor is consulting engineer.—C. H. Porier has examined the Alice, Pappoose, and Plummer claims for the Eastern Exploration Co. A 5-stamp mill is kept running on good ore.—Richard A. Riepe and Al Burton have taken a 60-day option on the Rosasco mine, three miles from Downieville. Three tunnels have been run on the property.—It is reported that 60 of the 125 men at the Sierra Buttes property near Sierra City will be laid off, and the No. 9 mill of 40 stamps on the river below the town will close down, leaving only the 20-stamp mill on the mountain running.

The 10-stamp mill at the Rainbow mine is making a satisfactory run. The upper tunnel will be extended south along the vein to prospect for another ore-shoot.—The Tightner vein is said to have been cut in the long development tunnel of the Rio Antiguo M. Co., operating on the South Fork property at Forest. The tunnel is being driven to tap the gravel deposit discovered many years ago by the Bald Mtn. Ext. Co., but several quartz veins have been cut by it.—A pocket of rich ore was discovered on the outcrop of the Tomboy vein in Lucky Dog ravine. The property is owned by Bixby & Son of Forest, and a cross-cut tunnel is being driven to cut the vein 100 ft. deep.

SISKIYOU COUNTY.

The Sheba mill on Patterson creek, in Scott valley, is ready to start.—J. H. Tibbetts has taken a bond from the Hegler brothers on their mines on Humbug creek. A 400-ft. cross-cut tunnel will be run on the property, which consists of five claims, near the Mono mine. An old tunnel is in 700 ft., and a five-stamp mill is on the ground.—The mill is running at the Mt. Vernon mine at the Greenhorn and Cherry Creek divide.—E. M. Brown will be in charge of L. O. Jillson's copper property at Whiskeytown.

COLORADO.

CLEAR CREEK COUNTY.

The old Dunbarton group of claims on Saxon Mtn., owned by John N. Stewart and Frank Strausser, is being worked again. These properties produced good silver-lead ore several years ago. The lower adit has 135 ft. to go before cutting the vein, and the upper adit, that is in 780 ft., is being cleaned out.—A find has been made in the Vidler tunnel openings, in a cross-cut from the main tunnel. The ore carries lead and copper. The main tunnel is in 4,450 ft., of which 700 ft. was driven on the west side of Argentine pass.—Behr & Fraser, operating a lease on the Bellevue-Hudson, have recently shipped 100 tons of ore to the Denver smelters. This is turning out to be one of the most important strikes made this year in the Columbia Mtn. dis-

trict. It is rumored that the company will ship concentrating ore to the custom mills at Idaho Springs. Machine-drills have been installed and work in the mine is progressing rapidly. John A. Holmberg is the manager.—The Plebian mine, on Columbia Mtn., is being worked through the Claypool tunnel. McKarahan & Parks are operating the property.—The Black Prince cross-cut of the Alaska holdings, situated on Green Lake Mtn., is in 100 ft., and will soon cut the vein.

IDAHO.

BLAINE COUNTY.

The suit that involved the Independence mines at Hailey has been dismissed and active operations should soon be resumed on this property.—A good body of ore has been cut in the Oriental group of mines on Roek creek. A drift has followed the ore for 175 ft. These claims are bonded to R. T. and Matt Tustin.

CUSTER COUNTY.

The Empire Copper Co. has been organized to take over the White Knob Copper Co. and the Macbeth lease, at Mackay. For the past 18 months the owners of the Macbeth lease have been operating the smelter formerly owned by the White Knob company, treating the ore from the mines of this company. The new incorporation was effected under the Maine laws, and the capitalization is for 1,200,000 shares of \$5 each. Frank M. Leland is the president and manager, and on the board of directors are John C. Montgomery, John H. Hobbs, Thomas J. Barbour, and R. L. Moffett. The company owns 38 claims and a mill and smelter, and the copper ore is said to average 4%. The mines are connected with the smelter by a seven-mile railroad, on which a Shay locomotive is run. Probably the old Van Nostrand tunnel will be continued, to tap the mine at depth. The 500-ton smelter produces copper matte that is shipped to Murray for treatment.—There is some talk of extending the Salmon River branch of the Oregon Short Line, which now terminates in Mackay, to the Salmon river.—The Brim brothers, who have been working the old Horn Silver mine at Era under bond, have struck a rich body of horn silver ore.

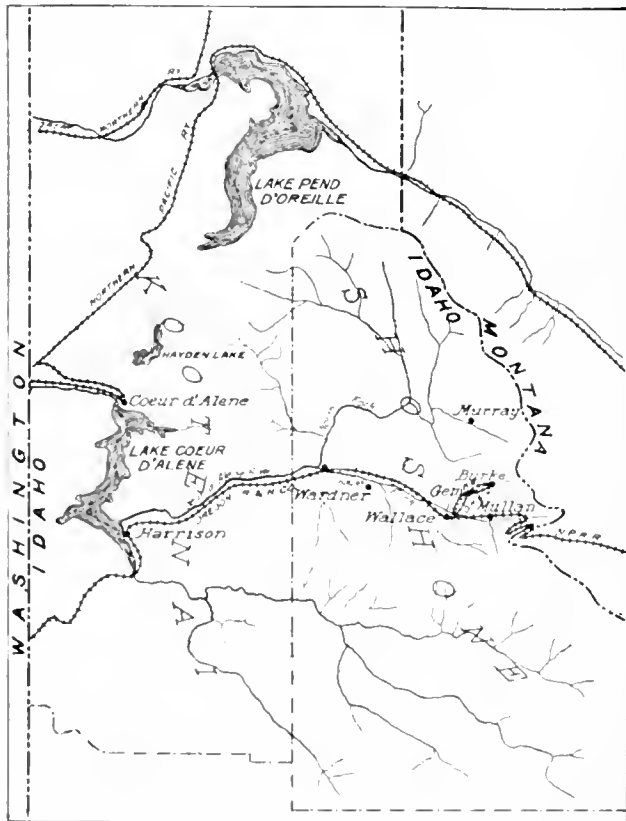

IDAHO COUNTY.

The Buster mine, at Elk City, should soon be a producer. A crew of thirty men is employed under Joseph Thorn. The raise from the upper tunnel to the surface has been finished and a 10-stamp mill and cyanide plant will be built.—Another vein has been discovered by James Larsen and W. G. Litchfield, in the 80-ft. tunnel in the Last Chance mine, adjoining the Buster.—Hopkins and Cone will install a small mill on the Eureka group of claims in the Newsome district. The property is developed by 550 ft. of work.—The Meadow Creek M. Co.'s new 25-ton mill, engine, boiler, air-compressor, and three drills have been shipped from Buffalo. Twelve men are employed at the property, and more are wanted.—The Golden Rule placer has had a prosperous year, and the owners, Tiedeman, Bosch, & Crisman, will enlarge the eight-mile ditch for next season's run.—On the Townsite property in the Steckner district, owned by Steckner, Thorn, & Brown, the tunnel is in 250 ft. and in 50 ft. more will tap the vein at a depth of 150 ft. The Big Elk and the Big Buffalo properties adjoining have good showings of ore.—The Hercules tunnel is in 450 ft. and taps the vein 250 ft. deep.—Jack Henniger reports the discovery of sulphide ore near the wagon-road at the west end of the Gold Dove, near the Lilly May.—A mill will be built at the Twin Butte property in the Orogrande district this summer.—Pat Brennan, who has been running the mill at the American Eagle under a short lease on the dumps, has secured a two-year lease on the entire property and will run the mill throughout the fall and winter.—The stamp-mill and cyanide plant on the Crackerjack mine, at Buffalo Hump, is running continuously and 22 men are employed. A year's supply of milling ore is blocked out in the mine.

OWYHEE COUNTY.

At the Village Blacksmith mine, near Silver City, work is being continued north in the adit that is in over 400 ft.

One ore-shoot has been passed through. A raise is being run between the two veins, for a double-compartment shaft on which an electric hoist will operate.—The 120-ft. shaft on the Commoner, purchased a year ago by the Security Mining Co., of which Lee Bunch is the head, is to be unwatered. This mine is near the old Golden Chariot, on War Eagle. The same company has bonded the Bullion and Yellow Jacket properties.—The Addie mill has been started for an experimental run on Potosi ore. Screens of 40-mesh are used and some gold is saved on the plates, but the saving in the pans has not been satisfactory and a table has been placed below the pans. About 600 tons will be treated in this experimental run, and battery samples show a value of \$56 per ton. Stopping has begun in the south drift from No. 2 level, and No. 2 level south, now in 470 ft., is being driven farther. The shaft will be sunk 100 ft. deeper, and work has been discontinued in the drift on

The Coeur d'Alene, Idaho.

No. 2 north, because an influx of water was feared from the creek above.—The Banner company has ordered a four-stamp Nissen equipment, that will be erected at the south end of the Coco claim, in Long gulch, recently purchased by the company from the Lewis brothers. The new mill will be connected with the present main tunnel by a tram-track 1,000 ft. long, on the west side of Collee gulch, and electric power will be purchased from the Trade Dollar Con. Co. The ore will be amalgamated and concentrated. In the mine, work is being continued in the north and south drifts from the tunnel level, and the raise for a shaft is within 70 ft. of the drift on the upper Banner level.

NEVADA.

CHURCHILL COUNTY.

(Special Correspondence).—Good ore has been found in both shafts on the Nevada Wonder, and development is under way.—At the Jack Pot the recently discovered vein showing up well, and shipments will soon be made.—It is reported that good quartz has been found in the lower level of the Ruby Wonder shaft.—At the Vulture, ore is being sacked for shipment, and the vein is looking well.—Active development is under way at the Hidden Treasure, Ajax, Blue Jay, Lost Chord, and Daisy.—Gasoline is selling at 60c. per gal., and as all the hoisting is done with gasoline engines, the problem of obtaining it cheaper is important.—Miners are getting 75 per day and are

scarce.—Water is brought eight miles from Bench Creek by pipes, and is sold at fair rates.

Wonder, August 1.

ESMERALDA COUNTY.

(Special Correspondence).—The production of the mines and leases of the Goldfield district for the week ended August 3 was 3,930 tons, valued at \$479,400. Of this amount, 2,482 tons, valued at \$310,250, was received by the Nevada-Goldfield reduction works from the following: Mohawk Florence, 375 tons; Mohawk Jumbo, 485; Mohawk Combination, 450; Mohawk, 440; Red Top, 275; Frances Mohawk, 80; Higginson, 130; Hayes & Monnette dump, 145; McNaughton, 60; Combination Fraction, 42 tons. The average value of the ore was estimated to be \$125 per ton. This is the heaviest production yet made in this camp.—At a meeting of the directors of the Consolidated Mines Co., held in this city today, it was announced that arrangements had been made for the retirement of the company's debt to B. Baruch, of New York, by which arrangement he and his associates would take treasury stock. This will leave the company free from debt with a large surplus. The directors will meet about Sept. 1 for the declaration of regular dividends. Charles W. Geddes, formerly of the Guggenheim staff, was appointed general superintendent of the Con. properties. The directors also decided to proceed with the preliminary work on the new mill.—The Goldfield output for July was 16,666 tons, with an estimated value of \$2,146,255.—The station on the 285-ft. level in the Kalfus shaft, in the Mohawk Combination lease, is completed, and driving on the vein will start at once.—Some excellent ore has been struck on the Red King claim.—The Daisy M. & L. Co. is about to ship 10 tons of ore from the 200-ft. level.—Ore has been struck in the 260 level of the Red Top. The vein is several feet wide and of fair grade.—Ore has just been encountered in the Gold Bar.—Goldfield and Colorado interests have purchased the Goldfield Storm King group. A shaft will be sunk on the principal claim.—The Frances Mohawk lease on the Wedge has struck some good ore. The shaft is being sunk an additional 100 ft.—A promising shoot of ore has been struck in the main shaft on the Great Bend No. 2 at Diamondfield. The strike was made on the 300-ft. level.—The Mohawk Co. has received \$85,900 for 90 tons of ore shipped to the smelter July 5, an average of over \$950 per ton.

Goldfield, Aug. 3.

NYE COUNTY.

(Special Correspondence).—The shaft at the Montgomery-Shoshone has reached the 550-ft. level, and a large flow of water has been struck. The cross-cuts on the 300 and 400 levels are in ore. The mine is shipping 125 tons of ore per week to the smelter, and it is expected that the mill will be ready for service by September 1.—At the Homestake excellent ore is being developed, and it appears that the value of the orebodies is holding with depth.—Development work is progressing at the West Extension, some excellent ore having recently been encountered in the south drifts. It is stated that a mill will soon be erected by the company. The Bonnie Claire is developing a large orebody. The 20-stamp mill is operating on good ore. Crude oil is used for fuel.—The Pittsburg Silver Peak 100-stamp mill at Blair is nearing completion. A large tonnage of ore running about \$14 per ton is blocked out. It is expected that the cost of mining and milling the ore will be \$5 per ton.—The stories circulated about the wonderful richness of the new camp of Eddy, in this district, had little foundation in fact. Investigation proved that the orebodies exposed on the surface gave out with depth. Rich silver ore was found, but existed only in one or two small pockets. When two small prospect pits demonstrated that the supposed veins failed to exist, the interested parties gave it up in disgust.

Rhyolite, July 29.

WHITE PINE COUNTY.

(Special Correspondence).—Reports state that the Consolidated Copper Co., with a capitalization of \$50,000,000, has been organized by Eastern interests to take over the

Nevada Consolidated, Cumberland Ely, and Ely Mines Co., in this district and properties in Bingham, Utah. The Ely group will be absorbed on the basis of one share of Ely for three shares of Consolidated. The others will come in later. The merger will embrace 2,880 acres of mineral land.—The Cumberland Ely is preparing to sink a new shaft on the Veteran group, and machinery for that purpose has been ordered.—Two No. 5 churn-drills have arrived for the Giroux company, and will be used for prospecting, and for tapping the water-bearing strata for additional water for the concentrators.—The Wedge shaft on the Cumberland Ely is being sunk as rapidly as possible, and some good ore has been encountered.—The Badger shaft at the Ely mines is down 200 ft. Cross-cutting on the vein is under way.—Three shifts are sinking the Chainman shaft, and the 160-ft. level has been reached.—On the Federal-Ely a tunnel is being driven to

Map of the New Mining Districts of Nevada and California.

tap the ore at depth. The Queen of the West shaft is down 100 ft. in sulphide ore.—Two churn-drills are operating at the Ely Giroux Extension, and some promising copper ore has been discovered.—The line from the Star Pointer shaft to Ely, a distance of eight miles, has been completed.—The surface equipment of the Joana shaft has been installed, and sinking will soon start.

Ely, August 1.

OREGON.

BAKER COUNTY.

George W. Boggs has secured a 10-year lease on the Peacock mine in the Seven Devils district. He claims there is ore developed that will pay to ship to Council.—The Razos Mining Co. has been formed in Sumpter to take over John Thomsen's group of claims in the Cornucopia district.—Fra Lemon has run a 200-ft. tunnel on his claim in the Greenhorn Mtn.—The Heppner coal mines will not be worked this year. The owners have spent several days in looking over the property.—A good coal stratum is being uncovered at the Lucky Boy mine, south of Bonanza, by Al. P. Johnson.

LANE COUNTY.

A contract has been let for more work on the Golden Slipper property on Horse Heaven creek, Bohemia, by Frank Tarkington and J. M. Gowdy.—Work continues at the Vesuvius with good results.—The Clarke brothers are developing their combination mine at Bohemia.—A force

of men is employed at the Baltimore G. M. Co.'s ground in the Champlon basin.—Eggin & Sweet, who own the Sunrise group of claims on Adams Mtn., will build a wagon-road to the property.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—Continued improvement is apparent at the Copper Key mine. From the stope near the surface the ore appears to be extending in all directions, and a drift runs northward from it 30 ft. that is entirely in ore.—Four Medford smelting furnaces have been received by railway for the Colville M. & S. Co., and there is another one in transit.—Some gold-bearing iron sulphide ore is being extracted from the Pin Money shaft, on the Oversight group. There is about a carload ready for shipment.—At the Winnipeg mine only one machine-drill is working at present, with two shifts. Miners are hard to get. The tunnel is in 950 ft., has passed through a syenite dike, the foot-wall of the vein, and has gone through 25 ft. of ore.—A strike of ore is reported on the Monitor group on Missouri Mtn.—Mining activity is increasing at Park City camp, additional wagon-roads are under construction, and the creeks are being spanned by bridges. Some copper ore is being extracted from the Hercules claim, below the Ramore Co.'s property.—The Columbia group is producing some rich silver-lead and copper ore.—During the past six weeks an adit on the Mountain View group has been driven 115 ft. and has about 280 ft. further to run to strike the main vein, 114 ft. deep, a contact between limestone and porphyry. The vein is 5 ft. wide, and some of the ore will assay \$16 per ton. The Mountain Maid vein on this group has been traced by sinking five shallow shafts.—The core-drill on the North Half group of the Colville M. & S. Co. was started July 20, and a vertical hole will be drilled 150 ft., at which depth it is expected to penetrate the silver-lead vein that is reported to be at the contact between trachyte and stratified limestone. The exploratory work thus far reported by the superintendent is an open cross-cut, a drift 20 ft. north, and another 10 ft. south on the vein. From the surface workings 15 tons of ore have been mined. About 15 tons more are reported to be in sight. The assays, as reported, run from \$50 to \$116 per ton, the principal value being in lead, with some silver and gold. Open work similar to that already done is planned to be duplicated every 50 ft. along the course of the vein, to determine its extent.

Republic, July 26.

(Special Correspondence).—The Oversight M. & M. Co., originally owning four claims on the south of Belcher Mtn., now owns 11 claims. Considerable exploratory work has been done on the group, at a comparatively small outlay, with satisfactory results. E. J. Delbridge is the manager. The exploitation of the group has resulted in uncovering several deposits of iron oxide and sulphide ore, characteristic of the neighborhood. The work consists of about 1,300 ft. of adits and drifts, 200 ft. of shafts from 20 to 80 ft. deep, and about 40 test-pits from 5 to 15 ft. deep. With the exception of a few of the latter the workings have disclosed low-grade ore, but the extent of the deposits has not yet been determined. The equipment of the property consists of a 15-hp. gasoline engine and an 8 by 10 in. straight-line air compressor. At the No. 1, 2, and 3 adits are large log ore-bins filled with ore awaiting shipment. The company owns also a 300-ton bin at a siding on the Belcher Mtn. railroad. The veins of the Oversight group are contacts between diorite, limestone and metamorphic sedimentaries. In the case of the Pin Money vein the hanging wall is diorite, and the foot-wall is slate. An overflow of trachyte covers the apex. A general average of the iron sulphide ore developed in the group is estimated at \$2.58 in gold and 10c. in silver per ton, \$3 in excess of iron, 1% copper, 42% sulphur, and 2% lime. There is sufficient copper in the ore to cover the slag losses in smelting and enough sulphur to furnish the matte. From a total gross value of \$5.60 per ton must be deducted the costs of mining, transportation, and treatment reported as follows: Mining, 75c.; freight and smelter charges, \$3.55; incidental expenses, 30c.; making the total expenses \$4.60,

and the net profit approximately \$1 per ton. The shaft has been sunk 80 ft. and drifts of 100 ft. have been driven on the Pin Money vein.

Republic, August 6.

BRITISH COLUMBIA.

The Rossland mines shipped the following tonnages during the week ending July 27: Centre Star, 3,420 tons; Le Roi, 1,925; Le Roi No. 2, 385; and White Bear, 105 tons of ore. Total for the week, 5,835, and for the year, 157,277 tons. There was a shortage of cars throughout the district, which curtailed the output. Ore from the old Centre Star dumps, which was taken out 10 years ago by Oliver Durant, is being shipped to the smelter. A prospecting shaft is being sunk on the Idaho, and cross-cutting is being done from the Centre Star shaft to the vein on the 13th level. The only work that has been done on the 14th level is to cut a station and put in an ore-pocket.—At the White Bear, development continues on the lower levels with good results.—A couple of carloads of ore are ready to be shipped from the Nest Egg property.

The Consolidated company's Trail smelter, in addition to Rossland ores, received the following shipments during the past week: Snowshoe, Phoenix, 2,297 tons; St. Eugene, Moyie, 512; La Plata, Kokanee, 132; North Star, East Kootenay, 68; Spokane, 34; Arlington, Erie, 26; Keystone, 25; Standard, 23; Rambler-Cariboo, Slocan, 23; Haitney, 6 tons of ore.—The Le Roi smelter, at Northport, received 1,925 tons of ore during the week, that was treated in three furnaces.

From Phoenix are reported the following shipments: To Granby smelter from Granby mines, 20,832 tons. To British Columbia Copper Co.'s smelter from the Mother Lode, 5,117; from Snowshoe, 1,785; from Oro Denero, 1,905; from Mountain Rose, 59 tons. To the Dominion Copper Co.'s smelter from Brooklyn, 1,440 tons; from Idaho, 288; from Rawhide, 2,485; Sunset, 1,365. To the Trail smelter from the Snowshoe, 2,635 tons. Total for the week, 39,911, and for the year, 648,575 tons of ore.—The Boundary smelters treated ore as follows: Granby, 18,223 tons; B. C. Copper Co.'s smelter, 10,938; Dominion Copper Co.'s smelter, 5,578 tons of ore. Total for the week, 34,739, and for year to date, 633,947 tons of ore.

The Consolidated M. & S. Co., of Canada, Ltd., has declared its regular quarterly dividend of 2½%. The properties of the company are showing favorable development.—The Granby smelter is producing a carload of copper per day, that is shipped to New York to be marketed. The Granby company owns 1,168 acres in the Boundary district.—The members of the New York syndicate having an option on the Gold Drop group on Wallace Mtn., West Fork, are expected to arrive soon in the Boundary.—Work is progressing at the Sudbury, in Deadwood camp, where a new electric hoist has just been placed in position.—Ten stamps are dropping at the Cariboo-McKinney mine, and the other ten stamps that are in the mill will be repaired and started.—The Black-Mackay Co. is employing 14 men in the Cambrian mine at Moyie. The company will be reorganized under the name of the Cambrian Mining Co., Ltd. A shaft will be sunk in the lake, at a distance of 250 ft. from the shore, where the water is 60 ft. deep.—The company operating the Payne mine at Slocan has been reorganized with a capital of \$500,000.—Some good ore is being struck in the Richmond group, near Sandon.

MEXICO.

SONORA.

The 60-stamp mill of the Greene Gold-Silver Co. has been in continuous operation since the first of the year, and with the treatment of between 150 and 200 tons of ore per day, earnings have approximated \$3,000 per day. Most of the money, however, is being put back into the property, and the mill is being enlarged so that within 60 days its capacity will be increased by 40 additional stamps. Owing to the introduction of some improvements the management is of the opinion that with 100 stamps in operation a total of 500 tons daily can be treated and at the same time costs can be reduced. An average of about \$10 per ton net is figured by the company against \$5 as average cost of operation.

Special Correspondence.

Denver, Colorado.

Creede.—Recent Discoveries.—Another Smelter at Canyon City.—Scarcity of Labor.—Sulphur in Colorado.—A Mica Mine.—Development in the Findley.—New Mill for the Independence.

Creede is a Colorado camp that attracts little newspaper comment, but which maintains a steady and considerable production of lead and zinc ores. The rich silver ores that first attracted attention to the district are now a matter of little moment, and, indeed, the Holy Moses, where the first discovery happened, made but little profit for the owners. Recently some very rich silver ores have been opened up on Campbell Mtn., and the properties there may perhaps give good account of themselves. One feature of the camp is the almost complete absence of the technically trained man. With rare exceptions all the mines are managed and operated by men who have gained their knowledge of mining in the school of experience. Recently the Creede area has been surveyed by the topographers of the United States Geological Survey and a strong effort is being made by those

Map of Southwestern Colorado.

interested in the district to secure the publication of the geologic folio.

Canyon City expects to have a new smelter. The Tri-Billion Smelting Co. has obtained concessions, and will shortly begin the construction of a large plant to handle the ores produced by its mines at Magdalena, New Mexico. With this addition to its present smelting facilities, Canyon City will rank as a smelting centre of no mean importance.—The deep drainage adit at Cripple Creek is being advanced by company men, and is now in about 300 ft. Easier drilling ground is expected soon, and meanwhile preparations to sink the intermediate shaft are being actively urged.

The drain of Nevada upon mining labor is being felt in all the camps of Colorado. Partly is this due to the higher wages obtainable in the newer camps, and partly to the roving disposition of the native-born miners, to whom the desire to see a new camp and the possibility of making a 'strike' themselves is a lure too strong to be resisted. The pay for the hours of labor is already high, but if the demand for men grows to any great extent it may force a further advance. In this connection it is worthy of passing notice that, as a rule, the wages paid for smelter and mill work are usually low, compared

with mine wages, although the work is neither less arduous nor calls for less skill, in fact, in many cases, quite the opposite is true. It seems certainly true that miners' wages are as high at present as the conditions justify.

The Colorado Sulphur Co., which is actively exploiting the sulphur deposits on Trout creek, in Mineral county, is advancing Colorado to a place among the important producers of sulphur. One of the chief sources of local demand for sulphur is in the making of sheep dip. For this use it is important that the sulphur shall be as free as possible from selenium, as the latter causes a perceptible darkening of the wool. The Mineral county deposits, which average 80% sulphur as mined, are almost absolutely free from the deleterious element, and the product is consequently in great demand among the ranchmen of southwestern Colorado.

The Cripple Creek district bids fair to stand sponsor for another industry in a mineral way. A shipment of mica was sent out from Wilbur over the Florence railroad, and this will be a test shipment for other properties in the vicinity. Fred Hackey is the gentleman who stands responsible for the new enterprise; his hopes are based on the present large demand for mica products and the extensive area of the mica belt.—A large amount of piping is being placed in the Findley mine on Bull hill, 11,000 ft. of 6-in. on this property, and about 2,200 ft. of 3-in. pipe in the Findley, Shurtloff, and Mountain Beauty properties. On the last a large orebody has been opened on the 800-ft. level and something like 3,000 tons per month is expected to be the result.—The Cresson is handicapped by bad air at the present time, but this condition is soon to be overcome by connection with a 60-ft. shaft and the 300-ft. level, which will ventilate the lower levels and various stopes as well.

The Jo Dandy mill is in operation, about 100 tons being handled daily. This is a new mill and has been running about ten days. A clean-up will be made about the first of the month, when its efficiency will be definitely established; so far the operations have been satisfactory.—Three gold bricks were consigned to the Denver mint as a result of a clean-up at the Phoenix mill of the Phoenix M. & M. Co., the bricks aggregating 160 oz., representing a ten-day run and 1,200 tons of ore of an average value of \$2.80 per ton.

The removal of buildings on the site of the new Stratton's Independence mill has been accomplished and trenching for the foundations is in full swing. The summer rains have interfered with this work. The consulting engineer, Mr. Philip Argall, is expected to arrive next week. The Stratton's Independence Co. has secured a counter injunction restraining the Portland Gold M. Co. from working along the boundary line pending the trespass litigation, consequently territory contiguous to the boundary is idle.—The railroad company is making a fill across the cave which recently occurred on the Stratton's Independence property and expects to be running trains across it in a few weeks.—The leasing system, recently started on the Ajax property, is now in operation, about 25 blocks being worked, with others to be let. The average value of the output is an ounce and between 30 and 40 carloads represent the monthly consignments.

The British American Leasing Co., operating on the Dante, has made connections through a 460-ft. shaft with the main workings of the Trail tunnel; a skip is being installed and the railroad is building a spur to facilitate loading. Regular shipments will begin in a few days from the ore already broken in the stopes, and the output is expected to be a car per day.—There is increased activity in the region about the town of Cameron, on the northern rim of the district. Eastern capital is invested, which is largely responsible in proving up the

dikes and veins that appear to be offshoots of the Bull hill system. A 3-ft. vein is being followed to its crossing with the Bull hill dike, which goes through the property of the Mayflower Gold Mfg. Co., under the management of lessee S. B. Stewart. Shipping ore is expected to be found at the junction. Several other operators are energetically at work with the aid of Eastern capital on Tenderfoot hill, which in the early days produced well in workings of from 100 to 200 ft. in depth.

Mexico City.

Branch Railroad From Guanajuato.—Transfer of Mines to American Companies.—Sale of the Palmilla.—Awakening of Parral.—Real Del Monte.

At last comes the most agreeable news that the great old mining camp of Guanajuato is soon to have an all-rail connection with the outside world. The date set for the formal opening of the Mexican Central's branch into the city of Guanajuato is that of President Diaz' birthday and the Independence Day, September 15 and 16, which will be made the occasion of a great celebration,

with P11,000 each. All of these, as well as the Cubo, Guanajuato Amalgamated, Republic, Carmen, Peregrina, San Prospero, Mexico Milling & Transportation Co., Nayal, Cabrastante, and others are foreign (principally American) companies. The final payment of P100,000 recently made to the old English company, United Mexican Mines Co., Ltd., for its last holding, the San Cayetano, by the San Cayetano Mining Co., Ltd., organized by Captain W. Murdoch Wiley, places all the properties now, from La Luz vein to the city of Guanajuato, a distance of several miles, in American hands. And there is no denying that this, though good prices have been given for all at the times purchased, is a sore spot in the side of the Mexican. His great old properties, in many cases abandoned, have gone from him and by modern methods and opening of great bodies of low-grade ore, the treatment of which is now made possible, are being converted into storehouses of great wealth by the omnipresent and omnipotent gringo. Envious therefore of the latter's success, the Mexican forgets that he put a price on his mine and got it.

What bids fair to be a forerunner of grand awakening

in the Parral district is the recent deal for the famous Palmilla mine of Pedro Alvarado. The fire which occurred there several weeks ago did not prove as disastrous as was at first supposed, but it evidently had some bearing in hastening the late deal. The property has in the last few years produced from P10,000,000 to P12,000,000, and made Alvarado, the sole owner, a very wealthy man, but his great extravagance and ignorance of the value of money soon ran him into debt, and at the time of the fire he was negotiating with Bert Peterson for a lease and bond on the property. The fire caused his needs to be even more pressing. Finding that J. F. Flynn and Eugene Davis (of Washington, D. C., and the Capuzaya Co., adjoining the Palmilla) were ready to make the necessary advance, he ignored the deal with Peterson and leased to Flynn and

Mexico.

for which many thousand dollars have been raised. And well may it be the occasion for a gala day, for after that date it will no longer be necessary to take that miserable ride for miles in a more miserable mule-car in order to enter Guanajuato, which a long-suffering people have more or less patiently stood for years. Why the people of Guanajuato have not long before this demanded a railroad connection cannot be understood, but of late years the foreign interests have been growing so rapidly that they would no longer stand for the street-car company's extortions, and were preparing to build in a road of their own had not the Mexican Central hurried and made the necessary preparations for doing so. It is but another example of the fact that Mexico has to thank the foreigners for forcing development of the country. And now that the Mexican Central has constructed this branch into the city of Guanajuato, private interests are preparing to connect the railroad with all the principal properties of the camp by means of a belt line for which a concession has been obtained by George W. Bryant, one of the principal stockholders in the great Pinguico mine, or the Guanajuato Development Co. This shows in part what a great camp Guanajuato has again become, as is also emphasized by the combined payrolls, which five years ago were little more than a pittance, and now amount to over P80,000 per week, being led by the Guanajuato Reduction & Mines Co. with P65,000, and the Guanajuato Consolidated M. & M. Co. and the Pinguico

Davis the Palmilla mine for a period of 15 years, at 45% royalty and P600,000 cash (P200,000 down and P400,000 in three months) to be deducted from the royalties. Flynn and Davis are already in charge and in a couple of weeks have unwatered the lower workings, which Alvarado, with an array of pumps and natives, has been unable to do in over a year. The transfer of this magnificent property by foreigners will undoubtedly be followed by many changes. The electric plant will be hastened to completion, and there is little doubt but what a mill and cyanide plant will soon follow. Both Mr. Flynn and Mr. Davis are among the most progressive men in Parral, having been operating in the camp for years.

The United States Mining, Smelting & Refining Co., is making many improvements to its Real del Monte property, near Pachuca. The old works are being transformed into modern plants and electricity is being applied in their operation. The old reduction works using the patio process have been converted into a cyanide plant, with 40 stamps and more than 10 Chilean mills. The capacity of this plant is 250 tons daily. Another cyanide mill is being built by the company. It will also have a capacity of 250 tons. The electric power for operating the machinery of the mines and mills will be obtained from the Compania Electrica e Irrigadora de Hidalgo. The amount of power required is 5,000 hp. The Real del Monte mines have been constantly worked since 1523,

when their exploitation was begun by the Spaniards. The Oxman Prospecting Co. is installing a 10-stamp mill at its mines near Guzapares, in Chihuahua. It is expected that the increase of production will soon require the establishment of an additional 10 stamps. Other machinery is also being installed at the mines. Frank Holmes is manager.

The Cabrillas company is doing a large amount of development work upon its mines in the Monterey district. A large body of rich ore was recently struck in the Santa Brigeda mine. Ore shipments are also being made from the Paloa mine, which is another one of the company's promising properties.

La Compania Minera de la Guadalupe has been organized for the purpose of operating the ancient Spanish mine of La Guadalupe, near Santa Engracia, in Tamaulipas. This mine was operated profitably many years ago, but was shut down when the price of copper got low. It is claimed that it contains a great body of copper ore that can now be worked profitably. The ore will have to be hauled by wagon 14 miles.

The Cambio Gold Mining Co. is installing a 30-ton reduction plant in the Rosamorado district, in Tepic. This company is composed of Cincinnati men. It owns several ancient mines and a large tract of mineral land that has not yet been explored. The development work has been in progress for two years and a large amount of low-grade ore is in sight. John A. Bender is general manager.

Butte, Montana.

July Production.—The Fire in the Minnie Healy.—Strike in the Lizzie.

The Farrell Copper Co.—Sinking on the Nipper.—Development of the Parrot.

In July the Butte mines produced 27,157,395 lb. copper from about 413,385 ton of ore, an average daily output of 13,335 tons of ore and 876,045 lb. copper. Although the Minnie Healy mine of the Butte Coalition Co. and the West Colusa of the Boston & Montana Co. were closed for several weeks during the month on account of the fire, the total output of the district was not affected, as other mines made up the loss occasioned by the shut-down of the two properties. The strike of ore-haulers having been settled, a number of the smaller mines resumed operations during the latter part of the month, including the Gallatin and J. I. C. of the Anaconda.

The average production of the different companies during the month was as follows:

Company.	Tons of ore.	Pounds of copper.
Boston & Montana.....	104,160	7,082,880
Anaconda.....	124,000	7,564,000
Butte & Boston.....	20,150	1,229,150
Washoe.....	10,850	651,000
Parrot.....	11,470	642,320
Trenton.....	12,710	762,600
North Butte.....	38,440	3,113,640
Coalition.....	44,950	3,011,650
Original.....	25,730	1,569,530
East Butte.....	7,750	589,000
Pittsburgh & Montana.....	9,300	651,000
Miscellaneous.....	3,875	290,625
Total.....	413,385	27,157,395

The astonishing story published by a Boston financial paper that there was a fire "raging" in the Minnie Healey, and that it was believed that the ore-shoot on which the Minnie Healey, West Colusa, and Leonard mines were mining was the crater of an extinct volcano, "and that the effects of the fire may prove more serious than the outside world has dreamed of," had the effect of creating a lot of indignation among officials of the Butte Coalition and the Boston & Montana companies, as well as among local business men generally. The inference

that an old volcano was furnishing the fire in the Minnie Healey is the purest sort of invention. At no time has the fire in the mine been "raging," and it has never reached the orebodies. The fire has for a long time been smoldering in the fillings of old stopes between the 600 and 700-ft. levels, and there is no fire below that point. While the men were driven out of the mine for a few days the fire made its way down to some of the lower levels, but that was insignificant and was quickly put out as soon as the air currents were changed and the gas was driven out of the mine. It was only recently that the exact position of the smoldering fire was ascertained, and now it will soon be absolutely confined and controlled. The former owners of the Minnie Healey filled some of the old stopes hurriedly and carelessly during the Heinze-Amalgamated underground warfare, and it is believed that the fire started in some of this old filling, composed of all sorts of trash sent down from the surface, including manure and hot ashes. "The fire in the Minnie Healey," said J. C. Adams, superintendent of the Boston & Montana mines, "is no more serious than that which has existed in the Anaconda mine for years. By systematic means we are overcoming it, and it will be only a short time before the three properties are in full operation again. In order to expel the smoke and gas from the mines we have commenced sinking an air shaft on the Minnie Healey, in the centre of the orebody, and this is going down at the rate of six feet per day. It is now down 500 ft., and will have to be sunk to a depth of 600 or 700 ft. before it can be used as an upcast to carry off the gases. This will take three or four weeks, but when completed all the gases will be brought to the surface, and it will be impossible for them to spread to the other connecting mines." Holes have been drilled into the fire zone and water is being poured through them, and it is only a question of a few weeks when the fire will be entirely extinguished. In spite of the shut-down of the mines, the Boston & Montana smelter at Great Falls has been running at full capacity, the Mountain View, Pennsylvania, Leonard, and East Colusa mines producing more ore than the Great Falls plant can treat.

Lessees working on the Lizzie claim, one of the Davis-Daly properties in the heart of the city of Butte, made an important strike of a copper vein at a depth of 100 ft. At that depth the vein has several feet of first-class ore and possesses all the characteristics of the profitable veins of the district. There have been stories published of other strikes in the Davis-Daly ground, but most of them are unfounded. One big vein has been cut in the Thomas claim by the long cross-cut from the 1,800-ft. station of the Original mine, but the ore is not high-grade. No other important veins south of the Thomas have been cut.

L. W. Harriman, one of the Minnesota farmers who became interested in Butte copper when the excitement was high, has purchased an eighteenth interest in the property of the Baltimore Mining Co., situated about three miles from Boulder, in Jefferson county, paying \$10,000 for it. A number of Butte men are interested in the property.—The troubles of the Milwaukee Gold Extraction Co. were supposed to have been settled when George H. Savage resigned as superintendent, but Savage has now brought suit for \$40,900 salary alleged to be due him, and has attached all the property of the company in the Red Lion mining district of Granite county, including the cyanide plant.—Some very encouraging developments have been made by the Farrell Copper Mining Co. during the past month. About 10 days ago a cross-cut from the 200-ft. level of the Alliance shaft passed through a well defined 7-ft. vein, 30 in. of which is good ore. It is not commercial in the cross-cut, however, but is merely considered as an indication of what may be expected with

further development. A drift has been run along the vein for about 20 ft. Considerable water was encountered upon cutting the vein, and the flow was so great that work had to be stopped until provision could be made for handling it. The company is considering plans for more extensive development of the property. The Alliance Co. has proved the mineral value of the ground adjoining the Farrell, and the belief is strong that the latter will develop into a good producing property.

The Butte Coalition Co. has temporarily suspended mining on the Nipper vein, which had been carried on through the shaft of the Parrot mine. There is much water in the old workings of the Nipper mine and there was growing danger that it would be tapped and let into the Parrot. A raise was being made from the 1,200-ft. level of the Parrot to the 1,000-ft. level of the Nipper when work was ordered stopped. The water in the Nipper is about 300 ft. deep, and as soon as some arrangement is made for handling it, work will be resumed.

Houghton, Michigan.

Concrete Work in Hancock Shaft. — Satisfactory Developments. — Keweenaw Copper Co. — Rich Ore Uncovered. — Concrete Shaft of the Bangor Mine. — Method of Sinking.

The concrete work which has been under way for the past three weeks at the Hancock Consolidated No. 2 shaft was completed last week. The concrete extends from the surface down to a depth of 30 ft. At its lowest point it is four feet thick; from there to the surface there are numerous steps decreasing the thickness to two feet at the collar of the shaft. Very little overburden was encountered at the No. 2 shaft and it was necessary to penetrate but five feet to reach the bedrock. This, together with the fact that the concrete was carried down 30 ft., insures an exceedingly strong construction at the collar of this vertical opening. The concrete, while filling and reinforcing the sides of the shaft, is also interlaced horizontally and vertically with old rails and heavy

The company had been mining about 75 tons of ore per day from the Nipper. — The new vein cut at a depth of 2,100 ft. in the Corra mine is being opened by the Coalition company and is developing into a splendid orebody that may make the Corra one of the most important mines owned by this company.

The Parrot company is doing development work in both the Parrot and Little Mina mines. The intention is to open the Parrot vein at a greater depth and also to cross-cut for the Never Sweat vein of the Anaconda, which dips into a portion of the Parrot ground. This vein is a large one and has produced an immense amount of high-grade ore. — The two veins that have been cross-cut on the 2,200-ft. level of the Anaconda mine are being opened by drifts and raises, and work on the cross-cut on the 2,400-ft. level is being slowly extended south toward the second vein, known as the south vein, because its apex is south of the shaft. The first vein has its apex north of the shaft, but at the 2,400-ft. level it is 500 ft. south of the shaft. The second vein is about 1,300 ft. further south at that depth and will not be reached for some time yet. It is not likely that any ore will be mined from this level in a year, and sinking in the Anaconda shaft has been suspended.

A 25-drill air-compressor is being installed by the Pittsburg & Montana Co. The compressor will furnish power for the lower levels of the mine, which are 1,100 feet deep, and will enable the company to mine and prosecute development work on a more extensive scale.

bands. Steel channel-beams are used as dividers between the compartments. The No. 2 shaft has now reached a depth of 210 ft. It has inside dimensions of 9 by 30 ft., containing five compartments, four for skip roads and one for ladders and piping.

The shaft will be sunk to a distance of 3,600 ft., when it is anticipated it will cut the Quincy vein. As yet the ground through which this shaft will pass has never been explored. Numerous other veins will be intercepted at various depths, among them the Hancock west conglomerate, Hancock amygdaloid, and Pewabic west conglomerate. Satisfactory progress is being made in the mining operations at the old No. 1 shaft. Good ore is being hoisted and a stock pile is rapidly accumulating. Underground development is proceeding with favorable results. Seven drills are now in operation, one in sinking and the other six in the lateral openings. The shaft is 20 ft. below the eleventh level or a total depth of 1,050 feet.

The development work at the Keweenaw Copper Co.'s property is progressing rapidly. The showing is most gratifying. About 2,000 ft. west from the Medora shaft the company is diamond-drilling for the purpose of ascertaining the outcrop. When this is determined it is proposed to sink another two-compartment shaft. The diamond-drill will probably cut the lode before the month is over and as soon as it does the new shaft will be started. It was the original intention to start a new shaft on the Empire tract, about three miles from the Medora shaft, but owing to the inability to secure men for the

work the idea was abandoned. Had a new shaft been started at the Empire it would be necessary for the Keweenaw to secure an entire new equipment, but at the point where work is now to be started this is unnecessary. The Medora shaft is now in rock which is believed to be the richest ever encountered in any mine in the Lake Superior region. Expert mining men who have visited the underground workings of the mine during the past month are surprised at the rich showing. The ground is heavily shot with copper, making it an ideal stamp-rock. At present there are 10 drills working in this shaft and a total of 1,700 ft. of drifts have been done. The lode averages 12 ft. The shaft is close to 700 ft. in depth; a station has been cut and the 675-ft. main level is started. At the 600-ft. sub-level the lode was reached by a cross-cut and found highly mineralized. The management intends to continue driving and sinking as rapidly as possible.

Toronto, Canada.

The American Institute.—Larder Lake.—The Strike at Cobalt.—Shipments of Ore.—A Discovery Near Elk Lake.

The visit of the members of the American Institute of Mining Engineers to Cobalt occupied about three days, during which the party inspected the principal working mines. Many of them expressed unreservedly their surprise at the richness of the orebodies in sight and admitted that they had previously been skeptical as to the status of the camp. The party also spent two days at Lake Temagami and neighborhood and before returning visited the Sudbury nickel mines and the newly opened iron deposit at Moose mountain. They were enthusiastically received and lavishly entertained at every point.

Larder Lake is profiting by the miners' strike at Cobalt, many of the strikers having found work there. Several new discoveries are reported, including a find on the properties of the Gold Horseshoe & Larder Lake Co., where a band of quartzite 60 ft. wide and extending over three claims has been found, apparently carrying good gold ore. Another find has been made on a claim of the Towline company. Prospectors and companies are busy doing assessment work to hold their claims, the regulations requiring that 30 days' work must be done within 90 days after registration. As this has been impossible in many cases, owing to the backwardness of the season, bad roads, and the pest of black flies, the Government has extended the time within which this must be done to September 30. Many claims are offered for sale very cheap, the reason being that the holders find development work too costly for their resources, and consequently have to sell for what they can get.

At Cobalt, many of the companies that have refused to concede the demands of the union are working with reduced forces, while others have closed down their mines, among the latter being the Drummond, University, and Silver Leaf. Some new men are arriving and the places of the strikers are being gradually filled. The Nipissing has 300 men at work.—Ore shipments for the week ending July 27 were 281 tons, the following being the shipping mines: Buffalo, 30 tons; Coniagas, 156; Hudson Bay, 22; La Rose, 40; Nipissing, 30; Tretthewey, 25. An important find is reported at the Foster, where 80 men are working. A new orebody has been struck which is said to assay \$15,000 per ton.—A fine sample of ore of about 30 lb. has been forwarded to Toronto from one of the locations of James Gifford in James township, a short distance from Elk lake. It resembles Cobalt ore in all essentials. Contracts have been let for the sinking of a 50-ft. shaft on the Elk Lake Mining Co.'s location.

Salt Lake, Utah.

Slime Plant at Mercur.—Utah Copper.—Ohio Concentrator.—Tintic Smelting Co.—Strike at Tintic.—Shipments From Park City.

The operation of the new slime plant, erected by the Consolidated Mercur Gold Mines Co. at a cost of \$25,000, has been demonstrated a success and the management has announced that the capacity will be increased from 400 to 600 tons of ore per day. John Dern, the president, states that by reason of the operation of the plant it will be possible to make an additional profit of 50c. per ton on the ore treated and that the value in the tailing will be reduced to about 45c. per ton.—The fifth section of the Utah Copper Co.'s mill at Garfield will be started next week, when the plant will be giving treatment to 2,500 tons of ore daily from the mine at Bingham. The sixth section will be in operation before September 1. At the mine, the company has five steam-shovels in operation, some of them being used to strip the surface overburden from the orebodies while the others are working on ore to supply the mills at Garfield and Copperton.

The Ohio Copper Co. is making satisfactory headway with the construction of its concentrating mill near the Dalton & Lake mine at Bingham. The steel structural material is being put in place and contractors expect to have the building completed before the end of September. The management hopes to have the plant ready for operation in November. The initial unit is being built to handle 2,000 tons of ore daily, and it is expected that the capacity will be doubled in 1908. The Ohio mine has developed into one of the big mines of Bingham. The company's engineers claim that there are 7,000,000 tons of ore averaging between 2 and 3% copper actually blocked out. The concentrate from the mill operated by the Ohio company at the present time contains from 20 to 22% copper, with additional value in silver and gold.—The Tintic Smelting Co., organized less than a year ago, is pushing the construction of its smelter near Silver City, in Juab county, for the treatment of gold-silver-lead ores. The foundations for the plant are practically completed, and the structural material and equipment is arriving. This enterprise is being promoted by a strong syndicate of Utah mining operators. It is expected that the smelter will be ready early in 1908.

What is considered to be the most important strike ever made in the Eagle & Blue Bell mine in the Tintic district has been confirmed. An orebody was encountered at a point 600 ft. north from the shaft in a portion of the mine heretofore unprospected. The shoot has been opened 50 ft. each way, with the actual dimensions to be determined. The ore is rich in silver; assays as high as 700 oz. having been obtained. The casing to the ore deposit carries copper ore 40 to 60% and is from 12 to 18 in. thick. The Eagle & Blue Bell is controlled by the Bingham Consolidated Mining & Smelting Co.—A controlling interest in the American Mining Co., at Tintic, has passed to Jesse Knight, of Provo, and the deal is to be ratified by shareholders next week.

The Treasure Hill mine at Park City has changed management. It is now controlled by Salt Lake and Provo mining men, who have also acquired the Kentuck group. The Treasure Hill Coalition Mines Co. has been organized to take over both mines, and an option has been secured on the Creole, an adjoining property. Extensive development will be undertaken at once.—The output of ore from Park City mines during July aggregated 8,637 tons.—The ore shipments last week from Park City mines amounted to 1,308 tons, the contributing mines and respective amounts being: Silver King, 748; Daly-Judge, 368; Daly, 85; Little Bell, 65; other mines, 12 tons.

Johannesburg, Transvaal.

Repatriation of Chinese.—Hot Debate at Pretoria.—Situation Accepted in Good Spirit.—Insufficient Kaffir Labor.—Poor Outlook.

"Well, what do you think of the repatriation of the Chinese?" is the question that almost every man has asked his neighbor during the past fortnight. Could all the replies to that question be put down in a book there would be a collection of extraordinary variety. Those people who know least about the working of the mines, and unfortunately the Government now in power heads this list, are jubilant over the prospect of seeing the last of the Celestial on the Rand. As a matter of fact, there is not a single member of the Boer Government who is a practical mining man, and who knows at first hand the needs of the industry. Their knowledge is purely academic.

The Progressives, who represent the mining industry, put up a splendid fight in Pretoria, during the debate on the Chinese question. Sir George Farrar, the leader of the Opposition, who was referred to by General Botha as the father of Chinese labor in the Transvaal, attacked the Government's policy in a vigorous speech. He defended the introduction of Chinese labor, and showed how much the Transvaal gold output has advanced since their advent. He made a strong plea for their retention, for the time being at least, and solemnly warned the Government that the gloomy times we are now passing through would be made ten times worse by the enforced departure of 17,000 skilled Chinese this year. The Opposition bombarded the Government position with the accusation that they had bargained with the Liberal Government in England to get rid of the Chinese, in consideration of a £5,000,000 loan for the Transvaal, which the Imperial Government has guaranteed, to be spent on the Boer farms. But in spite of the pleadings and threats of the opposition, the Government decided against the retention of Chinese. Already 500 coolies have left the Rand for China, their time having expired. In their original contract the coolies are allowed to re-engage for three years, but the Government would not allow one to sign on again.

There are people who still maintain that the fate of the Chinese is not sealed; that although 17,000 will be sent away this year, the Government will not let the balance go next year. This is mere foolishness. The Chinese will go, no matter what happens. The Boers are so firmly in power that they can afford to forget their election pledge of doing nothing to harm the mining industry. They are wise enough to see that they will gain most by sending the coolies out of the country. Their policy is to please their masters, the Liberal Party, who placed them in power, and who will keep them there so long as they stand pat on the Chinese question. And so, two parties, the Liberals in England and the Boers in this country, have played with the gold mining industry to gain their ends!

The Rand has been forced to start afresh on several occasions, and now she begins yet another chapter. It might be of interest to inquire what are the chances of success under the new conditions, and whether there will be an expansion or contraction in the future. In the first place, it is a pleasure to state that the leaders of the industry have accepted the decision of the Government in the finest spirit imaginable. While they are bitterly disappointed that their efforts at reducing working costs, so as to make the field of operations on the Rand as large as possible, have been completely upset by the removal of Chinese, the leaders are not inclined to skulk in their tents, but have come out manfully and declared their intentions of doing the best possible under the new

conditions. Almost every mining man of note predicts that the cost of production will increase when the Chinese go. The Government justifies its action by declaring that there are sufficient Kaffirs in the country to supply the mining industry. This is all bunkum. At the present time there might be sufficient labor, but the Kaffirs will not serve steadily, and it is the firm belief of those who know the labor conditions best, that there will not be a sufficient supply of colored labor to allow of expansion. Unfortunately the competition for Kaffirs will become so keen all over South Africa that the wages for black men will increase every year. We will revert to the same conditions as held just after the war. The writer has seen a Kaffir surrounded by four gentlemen greatly in need of a servant, all offering the black man work. The Kaffir asked the first man how much a month he could offer, and received the reply £3. This black man allowed the competitors to bid for his services, and although the last offer was £6 per month, an extremely high wage for a native servant, his highness the Kaffir said he would not work for £20 per month, as he had saved up sufficient to keep him for years.

Map of South Africa.

To keep the mines running it will be necessary to use an increasing supply of white labor, if it can be obtained. The Afrikaners will no doubt be attracted to the mines in large numbers, but unfortunately the mines cannot afford to pay more than 5s. per day to rough laborers, and it is feared the white men will not work very long for this wage. Then again the prices for skilled underground men have been so reduced since the strike that it is probable that the Rand will not attract skilled miners from overseas. Why, for instance, should a miner come here from America, when he can earn the same money in the States? Given the same pay, America will prove more attractive to the average Cornish miner than South Africa. It is now recognized that the Rand will be forced to find not only rough laborers like Kaffirs, but will also have to educate from the white men of the country, artisans and supervisors. At the present time there are a large number of men being taught mining. About half of the applicants are failures, and will never make good underground workers, but it is hoped that by persevering these underground schools will in time be able to turn out efficient miners.

Looking forward is trying to the stoutest-hearted optimism. Even under the unfavorable conditions the Rand will keep going, but it is the opinion of the writer that there cannot be any great expansion. The zenith of the Rand is past as soon as the supply of unskilled laborers is uncertain, that is, when the Chinese leave.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

BLISTER STEEL is steel made by carburizing wrought iron by heating it in contact with carbonaceous matter. It might also be made by so carburizing a low-carbon steel.

DURING the first six months of 1907 the dividends paid by the gold mines of Bendigo amounted to £50,504, while the calls or assessments were £119,894. The total of gold produced was 93,788 ounces.

TOPAZ usually occurs in gneiss or granite, with tourmaline, mica, and beryl, and often contains inclusions of liquid carbon dioxide. It crystallizes in the orthorhombic system, has a highly perfect basal cleavage, and is found altered to steatite and kaolin.

CONSIDERABLE QUANTITIES of turquoise have been taken out from the mines in the desert region of San Bernardino county, including many stones of large size, which range from 50 to several hundred carats. Some of the latter have sold as high as \$1,500 each. The color is mostly a pale shade, and large quantities have been sold.

PHOSPHORUS unites with iron in all proportions up to 26%. In pig iron it causes brittleness, especially when the metal is subjected to shock-like strains, but gives fluidity to the metal while casting, and tends to prevent blow-holes. Phosphorus lowers the point of saturation of iron for carbon, and in consequence phosphoric iron is always low in carbon; it can not be removed from iron in the blast-furnace.

THE world's supply of cadmium is chiefly derived from Silesia, where zinc smelters obtain it as a by-product. The metal is sold in little bars guaranteed to contain 99.5% pure cadmium. At beginning of 1906 the price was 725 marks per 100 kg., then, owing to demand, it rose to 1,500 marks in May of the same year. Since then quotations have fluctuated from 1,200 to 1,300, and recently, large quantities being required, prices further augmented to 1,250 and 1,325, according to amount and distance of journey.

THE metric system of weights and measures was legalized in the United States in 1866, and an international bureau of weights and measures was established near Paris in 1875 by concurrent action of the principal governments of the world. Under the direction of a committee, two ingots of pure platinum-iridium were cast in the proportion of nine parts to one part, and from one of these a number of kilograms were prepared, and from the other a number of metre bars, which were compared and one of each was chosen as the international prototype standard.

MOLYBDENUM is largely used for the same purposes as tungsten; but in addition thereto it enjoys many and varied applications in the chemical and ceramic industries, but the quantities used in others than the metallurgical line are but small. Although it is authoritatively stated that the action of molybdenum in steel is from two to three times as powerful as that of tungsten, technical difficulties have opposed themselves to the production of pure compounds at less costs; but as soon as a constant and reliable supply of the raw material shall be insured, these difficulties will be overcome. Molybdenum will then have a much wider range of application, inas-

much as it is already used advantageously for improving the steel for rifle barrels, for large guns, for propeller-shaft forgings, and also for wire drawing, as, if a certain proportion is added to the steel, this increases its elongation and improves its flexibility. Moreover, the manufacture of molybdenum steel is less complicated than that of tungsten steel, and as soon as a regular production of molybdenum ores can be relied upon the metal will become of great importance.

THE effects produced by electrostatic stresses are much more marked in the case of solid than in liquid or gaseous dielectrics, owing to the fact that chemically the former are more complex and structurally are less homogeneous than the latter. Conduction, as in the case of gaseous and liquid dielectrics, is due to the motion of ions, and varies with the applied voltage much in the same way as on these materials. With weak fields the resistance for given conditions is constant over a certain range in voltage. Its value, however, varies considerably, according to the temperature and hygroscopic condition of the material.

IN most masonry specifications is found a clause specifying that the sand for mortar or concrete shall be clean. But the results of tests of mortar to which large portions of loam or clay have been added have often been higher than those of mortar made with cement and pure sand. It is believed to be impossible to make a general statement in this regard, as in some cases it is a benefit and in others a detriment, depending upon the richness of the mortar and the coarseness of the sand. Lean mortars may be improved by the presence of loam or clay or the use of dirty for clean sand, because the fine material increases the density.

A CORPORATION may be formed for the purpose of acquiring and operating mines. At the outset it has no property. It is supposed to acquire it by purchase out of its capital. If it does not so acquire it, however, it commits no offense. If, however, its organizers or promoters falsely represent to the public or individual investors as an inducement to them to purchase shares of stock, that the company has acquired a given property when in fact it has not, they are guilty of obtaining money under false pretenses, and the District Attorney of the county where the false representations were made, would be the official to take charge of the prosecutions. If the United States mails are used in the effort to promote 'fake' mining schemes, another crime is committed of which the Federal officers could take cognizance.

GRAPHITE sometimes occurs in six-sided tabular crystals of the rhombohedral system, but commonly is found in imbedded foliated masses, often scaly, slaty, or earthy. It has a perfect basal cleavage, and breaks into thin laminae that are flexible, but inelastic. The purest forms usually yield a little ash upon combustion. The specific gravity varies with the amount of impurities, but is about 2.2. It occurs in beds and embedded masses, laminae, or scales, in granite, gneiss, mica-schist, and crystalline limestone, and is in some places a result of the alteration by heat of the coal of the coal formation. It is sometimes found in basaltic rocks, as with the metallic iron in Greenland. In the United States, the mines of Ticonderoga, on Lake George, have furnished much of the graphite, and some is mined in the Huronian slates of northern Michigan. A deposit was at one time worked at Sonora, Tuolumne county, California, and it occurs in Alpine, Kern, Los Angeles, and Fresno counties.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Leachable.

The Editor :

Sir—I notice in a recent article by Mr. F. L. Bosqui that he refers to that portion of the crushed ore which may be successfully treated by percolation in cyaniding as the “leachable” ore. So far as I can judge from the Century Dictionary, this is a correct use of the word, but it seems to me there should be a distinction between an ore from which the value may be removed on account of the soluble condition of the precious metal, and an ore through which solutions will pass on account of the physical condition of the particles. In other words, I should say that a mixture of sand and sugar was *leachable* because the sugar would dissolve, but that it was *percolatable* because the particles of sand were in such a physical condition that the solutions would pass between them. Is there any other way of distinguishing this?

FUSSY.

[Why not say ‘pervious’? Would not that express the physical condition indicated? ‘Percolatable’ won’t do; ‘percolable’ would be correct, but awkward. Try pervious or permeable.—EDITOR.]

Mining Schools and Their Graduates.

The Editor :

Sir—Your issue of April 27 contained a short editorial concerning the inaccuracy of college publications “in reference to appointments obtained by alumni.” This brought forth a letter from ‘One of Them,’ which appeared in your issue for May 25, in which he discusses the influence of these statements on a boy about to make a choice of a profession, the actual (?) discrepancy between the statement and the real job, and what a graduate should expect when he gets out of college. There is so much that is good, and true, in this letter that I hesitate to criticise even that portion which seems to me exaggerated, or misleading, especially as my acquaintance with college publications is quite limited. It seems to me, however, that he must refer rather to the publications of the State institutions such as he mentions than to those of the standard colleges, which we may perhaps consider of a higher class, and most of which are to be found in the Eastern States. The State School of mines, or the University, which is maintained by a State, is unfortunately in many cases a political football, the trustees and the president, sometimes even the professors, being changed when a new party or faction comes into power. The average Western legislator is not, and cannot be expected to be, up to the standard of the carefully selected board of trustees or overseers of the older institutions. Accordingly, in order to obtain the funds necessary for salaries, buildings, equipment, and libraries, it is necessary to impress the Legislature with the large number of students that is being prepared for future professional work, with the prominence which they are attaining after leaving the school, and, consequently, the credit which is being reflected upon the State. At any rate it is undoubtedly much easier to obtain funds by doing this than it is to try to educate the legislator up to a broader standard. For this reason I imagine that the statement made in the editorial, and elaborated by ‘One of Them,’ may be true of certain institutions. I do not, however, think that it is fair that all college publications should be included in this category. One of the instances which I presume ‘One of Them’ would consider as giving an exaggerated

idea of the possibilities of the mining profession to the student has recently come to my attention. I first saw it in a daily paper wherein it was stated in an editorial that “There never was a time when the entirely competent educated man was surer of handsome reward in business.” As an instance it went on to say that statistics of graduates of the Lawrence Scientific School “Show that Harvard’s recent graduates who have become mining engineers, although averaging only twenty-seven years in age, earned last year, on an average, \$2,390.” Further investigation showed the following conditions, as published in the Harvard Bulletin for June 12. The department was established in 1895, the first man being graduated in 1897. An investigation was undertaken by writing personal letters to each man who had been out of college at least one year, that is to say, graduates of all classes down to 1905 inclusive. The total number considered was 39 men, of whom 5 never engaged in mining work. Of the remaining 34, 26 had been heard from when the article was published. The occupations of these men are given as follows:

Mine superintendent	11
Mining engineer.....	6
Examining engineer.....	3
Mining geologist.....	2
Metallurgist.....	2
Teacher of metallurgy.....	1
Metallurgical supplies.....	1

The earnings of the men reported are:

Average for the first year after graduation.....	\$ 958
General average for the current year.....	2,390

The Bulletin goes on to state: “When it is considered that the average age of the men is about twenty-seven years (the oldest being not yet thirty-four), and that they have been at work on the average only a little more than four years, it must be admitted they have done well. Probably decidedly better than the average young doctor or lawyer.”

The number reported is about 76% of those who have followed mining, or 66% of the whole number graduated. Of the remaining eight it is stated that “One is reported to be very successful, and two others are believed to have done as well as the average.” Of course the men who are failures, or who are unfortunate, are those who do not reply to letters asking for information, but I believe that it might be reasonably assumed that the average salary for the first year is about \$900 for all graduates. ‘One of Them’ thinks that the effect of statements of this kind is to make the less fortunate graduate “dissatisfied and to discourage him by making him feel he has dropped behind.” On the contrary, if he has the right stuff in him it ought to make him hustle harder himself, unless he really doubts the truth of such statements, and ordinarily the graduates of an institution keep some track of each other by letter-writing during the first year or two after they are out.

If misleading reports are published, the graduate, and not the college editors, should be blamed, for this information is commonly obtained on blanks sent out annually to each graduate. It is manifestly not feasible for the editors to verify the returns made by each graduate. If, however, these replies are not strictly accurate it is a serious reflection on the college, for it has evidently failed in inculcating that regard for absolute truth which is the first professional requisite.

It seems to me that the instances of “reported and actual status,” given by ‘One of Them,’ sound very much as though he were approaching the same exaggerative tendency which he complains is shown by the college authorities; at least I have not happened to meet any such instances in many years and many miles of wandering. There are undoubtedly many misfits in the case of students who

study mining, as there are in other lines, but it has been my experience that the men who do not follow mining either send no returns, are put down as in 'business,' or give their actual occupation. That a man who has studied mining does not practice it, is no disgrace either to himself or to the college where he has studied it, and if he finds himself better suited for selling stocks and bonds, or for farming, or for running a railroad, the methodical habits which should be taught in every technical school should yet be of advantage to him. General Francis A. Walker once stated that several of our ablest railroad engineers had been graduated from the mining department of the colleges. Nor is this strange, for what broader technical training can a man receive than that which is necessary to the mining engineer, who is supposed to be a thorough chemist, metallurgist, electrician, machinist, and surveyor.

Does not 'One of Them' look a little too strongly at the dollars and cents side of the question? Certainly it is no reproach to be a successful assayer at \$75 per month if the Hungarian in the camp *does* get \$90. That a man when he gets out has an opportunity to learn the practical side of mining, by being associated in any position from mucker up, should be enough. I think 'One of Them' is correct in his view that the man who started mucking is generally better prepared to fill a position in authority than the man who started assaying, and I think the tendency now is to encourage the college graduate to begin underground. Yet there is a limit to this, and some technical papers, which have been advising the students to put in time sharpening drills, building tanks, running jigs, laying track, framing timber and putting it in, pounding a drill, and cranking a machine, apparently think the years of Mathuselah are ours. No man has a better opportunity than the assayer, if he so desires, to become thoroughly acquainted with the business side of the proposition. If, in addition to "his mechanical routine of 40 or 50 muffle-fusions," he notes the variation in values and in saving, and spends his spare time talking with the mine foreman, the mill foreman, the amalgamator, the bookkeeper, and others higher up, so far as possible, he can learn much more about the production of dividends than can the man who has spent all of his time earning the practical side of the underground part.

The point to which I especially objected in the letter referred to, is the very pessimistic view of the opportunities now open to the young graduate. From what I have seen of conditions during the past year, it unfortunately is not necessary for the present graduate 'to start at the bottom.' It would be much better for him if it were, but I am assured, by the older men at the head of those educational institutions whom I happen to know, that there has never been such a demand for the college graduate as there is today. I know, personally, that I tried to get a graduate of the 1906 class in Technology to make himself generally useful, at a salary of \$75 per month and board, about a small property with which I was connected a year ago. The only man who would consider it at all finally declined it because he thought he would get more experience with a larger company, which had also offered him a position. Last May, eleven months later, I found him in one of our larger mining districts as assistant to the manager, and practically in actual charge of mills treating 800 tons of ore per day. It probably would have been better for him could he have had the experience of a year or two at the bottom, but the indications are that he will 'make good' where he is. Good men are scarce, and men to fill responsible positions are sought from among those who have had a technical education more today than ever before. I am told that all of the men of this year's class at the Massachusetts Institute of Tech-

nology who are willing to accept positions are already at work, and that the average salary is probably in the vicinity of \$75 per month. These men are continually impressed with the fact that "the technical school cannot make an engineer; it can only give the opportunity for the young man to acquire a training which will make him first of all a man, and further to acquire a familiarity with the fundamental principles of science, which he ought to know in order to be an intelligent engineer."* They understand, as stated, that "they are going to a practical school on another man's money." But that the other man is not of the opinion that they are "for the first two or three years—of little value to any one" is evidenced by his willingness to 'put up.'

So I hope that no coming student may be deterred by the letter of 'One of Them.' It leaves unmentioned the pleasures and possibilities, the acquaintance with Nature, the actual production of real wealth, and the hosts of good fellows in the profession. Work is necessary for the achievement of success in any line, but there is plenty of room for the intelligent worker in mining, and the field is broadening.

GEO. A. PACKARD.

Boston, July 18.

A Fundamental Problem.

The Editor:

Sir—Your editorial on this subject certainly does not make a favorable case for the engineers. While dilating quite properly on the uncertainties of mining (wherein much of the charm lies) your article would tend to give a feeling of hopelessness to those unfamiliar with systematic mining whereby the element of risk is materially reduced and sometimes practically eliminated.

In gold dredging it is largely a question of the amount of money that it is advisable to spend in prospecting that determines the degree of accuracy with which a calculation can be made of the profits to be won. It is practicable to make such a calculation with more certainty than in many other forms of industrial enterprise. Manifestly if the investigation has arrived at a point where it is no longer doubtful that the property is worth the price asked, further prospecting to determine the value within narrow limits may be inadvisable as an unnecessary expense. Particular circumstances determine this question. If doubts remain there is nothing to do but proceed until they are removed.

I fully agree with you concerning the complaint that engineers often fail to be explicit. Clients need and should have specific advice. Shall they go in or stay out? If in, shall they stop or proceed, and how; in general, what shall be their next move? Beautifully written reports going into full details as to ore reserves and other engineering matters may be of little real value if leading questions such as the above are not freely and explicitly answered. On the other hand, advice without detailed information as to facts even from engineers of established reputation, is never so convincing as where the basis for deductions is made clear. Actual experience in mine management is valuable, but men who have spent years in the successful management of large properties are sometimes entirely unfitted to advise in the case of prospects or partially developed mines. Emphasis must be laid on the question of general experience. A man thoroughly conversant with conditions in one district may be at a loss in another, or unable to approach the particular problem with an open mind. It would seem that the field to choose from is somewhat limited if engineers who at some time have been retained by wellknown operators are compromised by such engagements. We have

*George F. Swain, Proc. Am. Soc. C. E., Vol. XXXII, p. 517.

in mind engineers having active relations with syndicates who can be fully depended upon for trustworthy advice. The personal equation determines their fitness or unfitness. In the search for a technical advisor it must be clearly recognized that the most reliable estimates of a professional man's ability can be obtained from members of his own profession.

HOWARD D. SMITH.

San Francisco, July 28.

EMERGENCY PIPE WRENCH.—A file, cold chisel, and monkey wrench make an efficient pipe wrench, except when the pipe is too large, such as a 5 or 6-in. pipe. In such emergencies the device here illustrated will be found

very effective, says the *American Miller*. Take three or four feet of new rope. Fray out both ends thin and put them together. Commence with tip ends and wrap tightly around the pipe until you have a loop. Then with a piece of pipe or a round bar for a lever, turn the pipe as you would with a pipe wrench.

EFFECT OF HEAT ON LARD AND MACHINE OILS.—Experiments have been made for the purpose of determining the effect of higher temperatures than ordinarily occur upon the friction set up in a given bearing by the oil film between the rubbing surfaces, pressure and speed being maintained constant. The oils experimented upon were common lard and machine oils, such as are used for cutting and lubricating purposes. The results obtained are doubly interesting, because of the rather extreme conditions of pressure, speed, and temperature under which the test was run, and because of the remarkable regularity with which the points, when plotted, fall on a smooth curve. A Kingsbury oil-testing machine was used, in which a vertical spindle ran between two opposed brasses in a bath of the oil under test, which was contained in a surrounding cylindrical case. The load on the bearing was applied by a heavy helical spring, passing through the side of the case and adjusted by a screw. The oil case and its attachments were mounted upon a hollow vertical spindle free to turn on the frame of the machine. The moment of friction of the journal tending to rotate the case was balanced by the torsion set up in a tempered-steel wire by which the hollow spindle was supported, and the displacement of the case was read off in degrees from a circular arc on the frame of the machine. Heat was applied to the case and contents by means of a gas flame. The results showed that up to 180° F. the coefficients of friction of both the lard and machine oils ran nearly together, the difference being about 3% in favor of the machine oil. As the temperatures increased, producing a corresponding decrease in the viscosity of the oils, the plotted curves showed that the friction coefficients become less, reaching a minimum at 190° for the machine oil, but continuing to decrease as much as 10% more with the lard oil, the curve becoming nearly asymptotic to the temperature axis, and showing no signs of change up as high as 280°. Evidently above 190° the machine oil disintegrates, and the film between the bearing surfaces begins to break down; hence the friction increases very rapidly with the temperature.

Benitoite.

This is a new gem mineral determined and described by George Davis Louderback, associate professor of geology in the University of California.

As the investigation has shown that it is a new mineral species, it has been called benitoite, because it occurs near the headwaters of the San Benito river, in San Benito county.

The most striking characteristic of the mineral is its blue color, and selected crystals cut in the right direction produce a beautiful gem stone that rivals the sapphire in color and excels it in brilliancy. The color, however, although fairly characteristic, is not an essential property, for very commonly parts of a crystal are colorless, while occasionally perfectly colorless small crystals are found. The color also varies in intensity in different crystals or in parts of the same crystal. When pale it is a rather pure blue. When more intense it assumes a violet tint. In addition to this variation in color in different parts of crystals, there is a difference at any one point, depending on the direction in which the light passes. In other words, the mineral is strongly dichroic, the ordinary ray being colorless, the extraordinary, blue. A section cut parallel to the basal plane is practically colorless, while sections parallel to the principal axis show the deepest color. To get the finest effect, therefore, gems should be cut with the table parallel to the principal axis, and this is in contrast to the sapphire, which shows its color best when cut perpendicularly thereto. If such a section, cut so as to give the strongest color effects, be examined with a dichroscope, the contrast between the images is most striking. The image of the extraordinary ray being freed from the colorless image of the ordinary ray, presents a remarkable intensity of color, very much deeper, of course, than can be seen by looking at the mineral in any direction with the unaided eye. In the lighter parts this color of the extraordinary ray is a slightly greenish blue inclining to indigo as it becomes darker, and is very similar to one of the axial colors shown by some cordierites; but in the more highly colored or thicker parts it is an intense purplish blue.

The mineral has proved to be interesting from the standpoint of its chemical composition. Prof. W. C. Blasdale, who kindly undertook the chemical analysis, reports the following composition: SiO_2 , 43.71; TiO_2 , 19.32; and BaO , 36.97. Benitoite is then a very acid titano-silicate of barium, and stands in a class by itself, both as regards acid silicates and titano-silicates. The blue color of much of the material may be due to a small amount of titanium in the sesquioxide condition.

ALTHOUGH India has long been associated traditionally with gems and gem production, it yields at present but a small part of the world's supply of such minerals. All the gems produced in that country do not approach in value the unset stones and pearls imported, which had an average value of over a half million pounds sterling per year. By far the most important gems of Burma are the rubies. The blue sapphires formerly obtained in the Kashmir State appear to have been exhausted of late, and no records are procurable. Ruby spinel is a common associate of the true ruby in Burma both in the gravels and in the limestone rock, and is often mistaken for it. Another Burma gem stone is the red tourmaline (rubellite), and some attempts have been made to work it, as it is of fine quality. The data of production, however, are variable and imperfect. There is considerable garnet production in Jaipur, in the mica schists of Rajmahal; also near Sarwar in the adjacent State of Kishengarh.

Pioche, Nevada.

Written for the MINING AND SCIENTIFIC PRESS
By JAMES W. ABBOTT.

Pioche, the county seat of Lincoln county, Nevada, is situated 28 miles almost due north by wagon-road from Caliente, a station on the San Pedro, Los Angeles & Salt Lake Railroad, better known as the Clark road. It is expected that a branch line now in process of construction from Caliente will be opened to Pioche in September of this year, when the town will be 352 miles by rail from Salt Lake City and 485 miles from Los Angeles.

Leaving Caliente, a picturesque town at 4,400 ft. altitude, the branch railroad runs for about two miles through a canyon. This widens out into Meadow valley, which ends 18 miles above Caliente in an oasis of trees and green fields, the site of an attractive agricultural settlement known as Panaca. Again the line penetrates a canyon, very narrow in places and about three miles long, when Duck valley is entered and followed to an opening on the northern slope of the Pioche spur of the Ely range. From the valley there is a gentle rise to the town of Pioche, which lies at an altitude of about 5,800 feet.

After the vicissitudes that marked the early history of the Comstock had passed, and a daily overland stage service over the central route had been established, Nevada secured from the mining world that intense interest which had been given to California. In spite of arid climate, hostile Indians, absence of railroads and settlements, the adventurous prospector gradually scattered over Nevada; the camps of Austin, White Pine, Pioche, and Eureka, with a score of smaller ones, sprang into life and added their record to the growing frenzy. Next to Virginia City, with its world-renowned bonanzas, Pioche was for years the most famous mining camp of that period.

William Hamblin, one of Brigham Young's missionaries to the Indians, was visited at his home near St. George, Utah, in the fall of 1863, by a delegation of his wards, who had brought with them some *panacare*, which in their language meant 'silver ore.' He soon closed a bargain to pay them for their information, and going with them found and located the Panacker lode, which was his phonetic interpretation of the *panacare*. Hamblin returned home, told of his find, and brought in other prospectors, who made locations.

For years Indian hostilities delayed the opening of the camp, but each year visits were made to it and many of the locations were kept alive. In 1868 F. L. A. Pioche deputed Charles E. Hoffman to purchase for him some of the rich claims. Pioche was a native of France, an argonaut of '48, and reputed to have become very rich. Hoffman was a metallurgist of considerable note. He secured for Pioche some of the best claims, which the latter conveyed to the Meadow Valley Mining Co., a corporation organized by him for that purpose. This company soon acquired other properties and became one of the two principal factors in the region, and Pioche's camp came to be known as Pioche.

John H. Ely and William H. Raymond, who had been operating unsuccessfully in a district considerably farther south, came in a little after Hoffman and secured an option on the Burke claim, which soon developed into a high-grade mine. They then organized the Raymond & Ely Mining Co., which at once became the great rival of the Meadow Valley.

The surface ore was principally horn silver (chloride), argentite (silver sulphide), galena (lead sulphide), and cerussite (lead carbonate), in varying proportions. Naturally the first attempt to reduce them was with

crude furnaces. The necessary material for these was packed on mule-back from Elko on the Central Pacific railroad. It had come by way of San Francisco around the Horn, for the railroad still lacked hundreds of miles of a connection with the Union Pacific. The fire-bricks came from Glasgow, Scotland, and were said to have cost over a dollar apiece.

It was a most wasteful process, but the ores were so rich that it yielded a profit. Hoffman had added another furnace, a Frenchman named Chubar had erected one, and so had Raymond and Ely, before everyone realized that the excessive cost of fuel and fluxes, of shipping the lead-silver bullion to distant refineries that levied heavy charges, and the impossibility of obtaining sufficient lead to recover all the precious metals in the rapidly increasing output of ore, necessitated the adoption of some other method.

Raymond and Ely brought in a five-stamp mill that they had used in their southern operations, and erected it near Panaca on a natural millsite, which came to be known later as Bullionville. It was a crude affair, crushing wet, with 750 lb. stamps, vats, pans, and settlers. The ore was simply crushed and amalgamated

Map of Eastern Nevada.

in the pans, without chemicals or heat. For many months they crushed ten tons per day, half the precious content went into the tailing, there was a cost of \$30 per ton (which probably included mining and hauling), but there was a daily profit of \$900, and the Raymond & Ely Co. prospered greatly.

The Meadow Valley Co. erected an elaborate 20-stamp mill at Dry valley, 10 miles east of Pioche, at a cost of \$100,000. Their metallurgist was Alexis Janin, who had acquired valuable experience at White Pine. Here the regular Washoe process was practised with salt, copper sulphate, and heat, but the ores were treated raw. The amalgam was strained in boiling water. At this temperature the lead, remaining liquid, comes through with the quicksilver and a much higher grade of bullion is produced. As the lead amalgam cools, the lead crystallizes out, so that at the next straining, cold, the lead remains in the bag and lead bullion, low in silver and gold, is obtained.

Production increased with astounding rapidity and with it a pathetic call for mills to treat the ore. The Pioneer five-stamp mill of the Raymond and Ely was followed by one of ten, soon enlarged to 20 stamps. Then came a custom 15-stamp mill with a Stetefeldt furnace in which the ore was roasted with salt to convert the gold and silver to chlorides. Then came another ten, the

- No. 12. Meadow Valley No. 3 east of the fork, on north branch of main vein.
- No. 13. Dump of the Newark, on the porphyry dike.
- No. 14. Mouth of Zero tunnel running off toward the south.
- No. 15. Ruins of hoist over Panaca shaft, west of the fork on main vein. Out of this shaft came most of the ore from which the Raymond & Big Mining Co. paid 17 dividends, aggregating \$2115,000 between March, 1871, and September, 1872.
- No. 16. Susan Duster hoist.
- No. 17. Dump at mouth of Amador tunnel. The mine is now generally known as the Williams.
- No. 18. Pioche West shaft-house. Belongs to Ohio-Kentucky.
- No. 19. Nevada-Tah machine-shop and Pioche Water Co.'s lower tank.
- No. 20. Alberta, one of the Ohio-Kentucky group.
- No. 21. Shaft over the Independent, now used as Nevada-Tah No. 1.
- No. 22. Upper water tank of the Pioche Water Co. About 400 ft. east of this tank the porphyry dike disappears under the shale.
- No. 23. Here a porphyry dike crops out through the limestone.

Raymond and Ely 30-stamp battery, crushing dry, with its chloridizing furnaces, and still another 10 stamps. All of these were erected at Bullionville. The Dry Valley mill was enlarged to 30 stamps, a 10-stamp plant was built in Condor canyon, a 20-stamp in Pioche, and the Mendha 10-stamp at Highland, eight miles west. But these did not fill the needs and ore was sent to Silver Park, 42 miles to the north, and even to White Pine, 160 miles away.

A smelter was built at Bristol, 20 miles to the northwest to treat the rich ores of that locality, and later a stamp-mill with pans and settlers was erected, and still later another smelter.

All this activity meant life at full tide. The following are a few of the high lights in an intensely interesting picture: A daily line of six-horse Concord coaches carrying U. S. mail and Wells-Fargo express to the Central Pacific railroad at Palisade, through Hamilton (White Pine), a similar line to Salt Lake City, both operated by the famous Western stage-men, Gilmer and Salisbury; three daily lines, two of them running six-horse Concord coaches, to Bullionville; three lines of railroad organized to build into Pioche with the utmost possible speed; the Salt Lake City, Sevier Valley & Pioche railroad (a Mormon line), the Elko, Hamilton & Pioche (a Gilmer & Salisbury line), and the Palisade, Eureka & Pioche railroad (controlled by D. O. Mills), the Western Union telegraph to San Francisco by way of Palisade (Pioche was long one of the Western Union's principal Western offices), and the Deseret telegraph (Brigham Young's line), through Salt Lake City, 32 steam-hoists with their chorus of whistles, a fast freight mule-line running day and night, with regular stations for change of stock, carrying freight under contract for delivery in five days (with penalty for failure) from Palisade to Pioche (260 miles), a narrow-gauge steam freight railroad from Pioche to Bullionville, past the mills at Dry Valley and through Condor Canyon, two daily papers with Associated Press service, in the cemetery the graves of 78 men who died a violent death, 72 saloons, 3 hurdy-gurdies (dance-halls, two white and one variegated), 32 *maisons de joie*, with intimate correlation in the last four items, two good theatres, two breweries, two gravity water-systems with street mains and fire plugs, and two hose companies, a livery stable with 300 horses, and a population in Pioche and immediate vicinity of about 10,000 people.

The Pioche range is an east and west anticlinal fold, about fifteen miles in length with Pioche near its centre, joining on the west the Highland range, the general direction of which is a little west of south. The formation normally consists of Cambrian quartzite below, shale in the middle, and limestone on top. The composition, texture, and metamorphic condition of each member differs in different places, but the quartzite is hard and tough, so that there is little tendency to disintegration either at surface or underground.

Facing the town, there is a typical fissure-vein; it runs nearly east and west, approximately parallel to the anticlinal fold in the quartzite, which has been raised between two fault-planes to a height considerably above the flanking members. This vein splits.

Dr. R. W. Raymond, then United States Commissioner of Mining Statistics, visited Pioche in 1872 and his observations are recorded in 'Mineral Resources West of the Rocky Mountains,' 1873, pages 176 to 180. Imagining his reader standing on the surface where this vein forks, he says: "Behind him rises the mountain, before and below him clusters the town of Pioche. To the right the two divergent branches of the vein are thickly set with shafts and hoisting works. They differ in their

course about twenty degrees. To the left (west) the single vein continues, barring a break, caused by a barren cross-course of brecciated mineral mischievously interjected by nature to help the lawyers. West of this bifurcation the Meadow Valley Co. holds 340 ft.; east of the same point the same company holds 1,520 ft. of continuous mining ground, through the whole of which the workings of the company extend, constituting a magnificent mine. Next to the Meadow Valley mine on the west comes the Panaca mine of the Raymond & Ely Co., containing the most remarkable body of high-grade ore now to be seen on the Coast."

Several hundred feet south of this vein, between it and the top of the mountain and also running approximately east and west, is a porphyry (rhyolite) dike, which has probably played a controlling influence upon the formation of all the orebodies in the hill. Running into this dike in various directions, through it, across it, and alongside of it, are seams of all sizes and kinds. Upon the veins and seams above described were located the claims of the numerous companies whose varying fortunes constituted in the main the history of Pioche, a history so complex and involved that no analysis of it could be made in a short article. Remoteness from the railroad, the inevitable change in the character of the ore as depth was gained, legal controversies, quarrels about how the drainage should be handled, and the water problem generally below 1,200 ft., frenzied gambling on the San Francisco Stock Exchange, the failure of the Bank of California in 1875 (which bankrupted the principal stockholders in both the great companies) were all contributing factors in the decadence and final paralysis that followed the boom.

A new day has dawned for Pioche. When the railroad comes the mines will again be opened. Large bodies of ore that could not be handled profitably in the early days are still left in the various properties. Much virgin ground exists above the water-level, the vein dips toward the porphyry dike, in which splendid bodies of ore were disclosed before the pumps were pulled. What is to be found where the vein and the dike join will not be known until the junction is reached, but there is reason to expect important orebodies. The old dumps at Bullionville, Dry Valley, Condor Canyon, and the mines of the district possess ore known to be worth \$5,000,000, and this material will all be profitably treated. What the district has actually produced in money received for ore and bullion will never be known. There is good reason to believe that it exceeded \$40,000,000. This came principally from high-grade ore. The new Pioche will be able to produce a large tonnage, with all facilities for handling medium-grade complex ores. Gold, silver, lead, copper, and zinc in large quantities are now found in Pioche and its tributary camps.

The Nevada Utah Mines & Smelters Corporation owns the property once held by the Raymond & Ely and Meadow Valley companies, including some of the best mines in the Bristol district, the Half Moon and Manhattan groups, and its joint holdings with the Ohio Kentucky.

The Ohio Kentucky Mining Co. (a Newhouse corporation), owns a group of which the Susan Duster, a comparatively new discovery of great promise, has been most developed. A porphyry dike having no known connection with the main porphyry dike of the region runs through this property. The company owns jointly with the Nevada Utah some of the best of the old mines on the main porphyry dike. The Phoenix Reduction Co. (another Newhouse corporation), owns an extremely valuable group of silver-lead-iron claims near Pioche and the tailing piles at Bullionville and Dry Valley.

Other companies, some of them owning deposits of large value, are actively at work, and most of them will be shippers as soon as the railroad reaches Pioche. Without disparagement to any properties of merit inevitably overlooked in preparing such a list, there may be mentioned as immediately or prospectively within the shipping class: The Bristol Consolidated Mining Co., the Butte & Bristol Mining Co., the Ida May Annex group, the California Pioche Consolidated Mining Co., the Bristol Pioche Mines Co., the Poorman, the Mendha Nevada Mining Co., the Demijohn Pioche Mining Co., the Boston & Pioche Mining Co., the Lincoln Nevada Mining & Milling Co., the Lyndon Mines Co., the Ely Valley group, the Nevada Horn Silver Mining Co., the Pioche Mines Co., and the Cuprite King, West Point, and Milwaukee groups.*

Production of Lead.

The United States Geological Survey has issued a preliminary statement covering the production of lead in 1906. This has been prepared by J. M. Boutwell.

The following statement of the production of refined lead in the United States during 1906 embraces all desilverized lead produced at works in this country and the pig lead recovered from the Mississippi Valley lead ores. It is exclusive of a product of 10,516 tons antimonial lead reported by refineries. About 25,000 tons of pig lead derived from the Mississippi Valley ores was desilverized and is therefore included under desilverized lead and not under soft lead.

	Tons.
Production of desilverized lead	313,888
Production of soft lead.....	90,783
Total production of refined lead.....	404,669

The figures for consumption include end products only. Thus: Stocks, both domestic and foreign, and production are in terms of refined lead, imports and exports are in finished state, and antimonial lead is in marketable form, while lead in ores and bullion is excluded.

CONSUMPTION OF LEAD IN THE UNITED STATES IN 1906.

Supply—	Tons.
Stock, domestic, beginning of year	3,975
Stock, foreign, beginning of year.....	56
Total production, refined lead.....	404,669
Total production, antimonial lead	10,516
Imports, foreign refined	11,783
Total available	431,009
Withdrawn—	
Stock, domestic, close of year.....	4,571
Stock, foreign, in bond, close of year	64
Refined in bond from foreign base bullion and ores and exported.....	48,558
Lead in manufactures exported under drawback	1,516
Total withdrawn	54,709
Apparent consumption of lead in the United States in 1906	376,300
Quantity, tons. Percentage.	
Increase in consumption in 1906.....	29,285 8.44

The product of refined lead cannot be apportioned according to sources of ore from which it was derived, owing to the fact that lead refineries treat products which are secondary and are derived from diverse sources. The identity of ore, and thus its original source, is preserved only as far as the smelter. Accordingly, the following table showing sources of lead produced in the United States is based upon smelter figures. It includes 'pig lead' reported by all known smelters running on Mississippi Valley lead ores, and 'lead' produced at all other known lead smelters in this country. Returns from all known Canadian lead smelters state that in 1906 they did not treat any lead ores from the United States.

* The writer desires to express to Dr. Fred. J. Pack of the University of Utah his acknowledgments for valuable information derived for this article from his monograph on the geology of Pioche, published in No. 3 and 4, Vol. XXVII, *School of Mines Quarterly*.

*Exclusive of 12,339 tons lead derived from Mexican bullion.
†Including, according to special reports, 25 tons lead from Texas.

The Prospector.

Enquiries sent to this department are answered free of charge, is submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The specimen from Sacramento marked B. W. is Obsidian.

The specimen from F. B. W., of Gardiner, Mont., has not been received.

The blue-black mineral in the andesite marked 'Comer' is Magnetite.

We have not received the rock specimens from H. L. S., of Zihuatanejo, Mexico.

The calcareous Shale from A. G. of Tombstone, has no value unless it could be used in the manufacture of cement.

C. T., Paris, Cal. Ordinary opal has no value. The value of the gem variety depends upon its beauty, especially the play of delicate colors.

The brownish flakes in the andesite sent from Tonopah by E. A. C. are decomposed Biotite. Another type of alteration gives glossy white flakes.

The specimen of mineralized Basalt sent from Valdez, Alaska, by W. H. B., might carry gold and silver, though we would hardly expect it to be of value.

W. C. R. sends from Aura, Nevada: No. 1, Quartz, Chalcocite, Malachite, and Azurite; No. 2, Quartz stained with copper; No. 8, Quartz and Limonite; No. 4, Opal and specular Hematite.

The six rock specimens sent from Silver City, New Mexico, by T. L. G., are: No. 1, Basalt; No. 2, Quartz, Calcite, etc., and probably a decomposed Andesite; No. 3, Sandstone; No. 4, altered Andesite; No. 5, Basalt; No. 6, Andesite.

Lodes in the Tertiary Eruptives of Colorado.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

These form the prevailing rock in several important mining districts, notably Cripple Creek and the San Juan region, the latter being a comprehensive name covering a group of five counties in the southwestern portion of the State. The relative age and chief characteristics of these new volcanics are best studied among the mountains of the San Juan, where their relation to the earlier sedimentaries is made evident in a number of splendid sections. These show the Mesozoic rocks to be unconformably covered by a bed of Tertiary conglomerate, which, in turn, is conformably overlaid by a vast thickness of volcanic breccias, alternating with various flows of lava, the entire succession forming a rock-series of great interest both to the geologist and to the miner.

The conglomerate under the breccia is notable as being the youngest sedimentary terrain in which profitable gold-mining is being carried on within the boundaries of Colorado. Whitman Cross named it the San Miguel formation, but upon ascertaining that this term had been used previously by the Texas geologists he changed it to the 'Telluride' formation.¹ The evidence indicates that it is of early Eocene age.² It is a conglomerate of varying texture, usually coarse where it is thin, and graduating into fine-grained grits where it attains a considerable thickness; this ranges from about 200 ft. to a maximum of 800 to 1,000 ft. In Canyon creek, above Ouray, and in Bear creek, near Telluride, excellent exposures of this conglomerate can be observed. It is traversed by gold lodes. Of these, the Contention vein is the most important.

The workings of the Contention mine follow a vein into both the andesite breccia and the underlying conglomerate, as shown in Fig. 1. The vein marks the line of a fault, the vertical throw of which is 58 ft. Under the conglomerate comes the unconformity that marks the line of contact with the older sedimentaries, represented by Jurassic sandstone and shale. The measurement of the fault was made in a ravine that approximately follows the line of dislocation, the extent of which was made clear by comparing the severed portions of a bed, eight feet thick, of agglomerate, yellowish red in color, forming a well defined parting between the top of the conglomerate and the base of the breccia.

Fig. 2 and 3 illustrate the vein when traversing conglomerate and breccia, respectively. In the former the vein-stuff under the hanging wall consists of quartz-filling in a matrix of crushed conglomerate, while the under- and larger-portion of the width enclosed within the apparent boundaries of the lode consists of conglomerate that is obviously little altered, although partially shattered. The separation from the outer country is marked by selvages of clay. When the vein is in breccia (Fig. 3), the filling is crushed and cemented by the quartz in which the gold is disseminated. Within the lode there are irregular streaks of clay and dark pieces of the andesite surrounded by quartz. The boundaries of the lode are marked by parallel seams of clay and an outer casing of shaly country.

The best ore was found in the lower adits, which are situated near the base of the conglomerate. This averaged \$8 to \$8.50 for a width of 30 inches. In ascending, the vein becomes poorer; in the breccia it is smaller and the occurrence of ore is more erratic, although probably

as rich as in the conglomerate. In descending, and when penetrating the Jurassic sandstone and shales, the Contention vein becomes unprofitable and no exploitation has been tried beyond a little exploratory work.

The Telluride formation rests upon the succession of older rocks so as to indicate an unconformity of far-reaching extent. This has been proved by the work of the U. S. Geological Survey, under Whitman Cross, who, speaking of this bed of conglomerate, says: "Its base is first found resting on the Colorado Cretaceous shales and from that horizon gradually descends, transgressing the edge of the Colorado and Dakota Cretaceous, the entire thickness of the Jura, and is seen in contact with the Trias. In the districts south of Silverton it is believed that the Telluride conglomerate passes over the entire Paleozoic section and may come to a contact with the Algonkian quartzite of the Needle Mountain area."³

There is reason to believe that the Telluride formation may be correlated with the 'Arapahoe conglomerates' of the Denver basin, this being a series 900 ft. thick, made

Fig. 1

up of clays, sandstones, and conglomerates overlaid by the so-called 'Denver beds,' which consist largely of fragmentary conglomeratic andesite, especially where they rest upon the Arapahoe. There is also a suggestive correspondence between the relations of the Denver andesite debris and the Arapahoe conglomerate on the one hand and the San Juan andesite breccia and its underlying Telluride conglomerate. This indicates that big lava-fields of andesite existed formerly in the mountains behind Denver and these, by erosion, were removed and then laid down as sediment in the waters of the Denver basin; it is likely that this process of removal continued until erosion had cut down into the rocks on which the lava lay, because in the upper portion of the Denver series there is a notable increase of Archean schist in the composition of the conglomerate, the coarseness of which is also more marked.⁴

The variations in the composition of the Telluride conglomerate are evidently traceable to the variety of the underlying rocks by the disintegration of which the material of the conglomerate itself was obtained. Pebbles of quartzite, limestone, sandstone, schist, granite, and diorite all enter into the composition of the conglomerate.

¹The age of these rocks was first recognized by R. C. Hills. See *Proceedings Colorado Scientific Society*, Vol. 111, p. 174, December, 1888. See also 'The San Miguel Formation,' by Whitman Cross, *Proceedings Colo. Sci. Soc.*, Vol. V, pp. 235 to 241, September, 1896.

⁴Geology of the Denver Basin in Colorado, by S. F. Emmons, Whitman Cross, and George Eldridge. U. S. Geol. Survey, Monograph XXV11, pp. 202 and 203.

The period during which the San Miguel formation was laid down apparently just preceded the first of a cycle of volcanic eruptions, which occurred in the San Juan region in early Tertiary time. The conglomerate was probably still under water when it became covered with the products of volcanic eruption in the form of showers of fragmental rock, now appearing as beds of tuff and breccia of enormous thickness. This is the San Juan formation.⁵ It consists essentially of fragmentary andesite and attains a thickness of 2,000 to 2,500 ft. A good section of the entire series of beds can be seen on the trail going up to the Sheridan mine from the upper San Miguel valley at Pandora.

Numerous veins, rich in the precious metals, traverse this formation; they can be observed as bands of bleached and iron-stained rock, appearing as seams on the face of the dark cliffs and making deep trenches on the ridges where weathering has eroded them. These veins have made the San Juan region a great mining country. They are probably the most persistent lodes in Colorado; while

extruded not from one, but, in all probability, from several vents, none has yet been found. It is most likely that the crystalline rock which finally plugged any volcanic throats that may have existed, now forms the core of one or more of the mountain masses of the region and that subsequent erosion has spent itself upon the softer breccia, cutting deep ravines through it and into the underlying sedimentaries, over which the far-reaching volcanic débris was ejected with such lavish profusion.

The volcanic area of the San Juan is separated from the Cripple Creek region by the deep channel of the Arkansas river and the serrated range of the Sangre de Cristo. It is about 70 miles from the northeasterly edge of the one to the southwesterly outskirts of the other. Midway between them, although not directly between, there is a small group of volcanoes forming the Rosita hills, among

Fig. 2.

they have been worked for a notable linear extent, they have also been proved to be profitable to an unusual depth. Thus, the Virginius vein, on the Ouray side, has been worked for a longitudinal distance of over 3,000 ft., and to a vertical depth of 3,300 ft., while the Smuggler-Union has produced ore for a length of nearly two miles along the vein and to a depth of 1,200 ft.

In considering the depositories of gold and silver which occur in Tertiary eruptives one cannot omit a reference to the Cripple Creek district, although a good deal has already been written on the subject.⁶ Cripple Creek is of particular interest when regarded from the standpoint of the present paper because it is a goldfield where Eocene volcanics abut against pre-Cambrian granite, and the gold-veins penetrate both. At Cripple Creek, moreover, a true volcano existed. In the San Juan region the occurrence of enormous masses of fragmentary volcanic material has not been connected with specific points of eruption. Although the breccia must have been

which the mining district of Silver Cliff is situated. Here extraordinary occurrences of rich silver ore have been found actually lying in what appear to be undoubted volcanic conduits, the result, apparently, of such fumaroles or vapor vents as usually mark the last stages of volcanic activity. In the case of the two principal occurrences, in the Bassick and Bull-Domingo mines,⁷ the rich ore has formed a coating upon pieces of agglomerate lying in chimney-like openings through which aqueous vapors, rather than dry gases, must have circulated. This district, situated in a depression between the Sangre de Cristo and the Wet Mountains, serves as a link between the San Juan and Cripple Creek. The latter, which is 40 miles to the north, is to be studied in the light furnished by the miniature volcanic complex of Rosita. Both may be considered, according to Whitman Cross, "as small outlying vents connected in origin with the much larger eruptives of the San Juan and of the South Park regions, which were in part also of Eocene age, though probably continuing into the Miocene."⁸ To the miner the two districts present a great contrast, Rosita being characterized by local enrichments which

were uncertain and short-lived, while Cripple Creek has permitted of extensive and successful mining over a long period of time. Both are characterized by several small vents and a succession of eruptions rather than one period of overmastering energy. Both illustrate the complete cycle that marks the life history of a volcano, from the gradual accumulation of energy which causes the first spasmodic eruption to the slowly dying breath of solfataric action and the outpouring of thermal waters; the last being, it is believed, the period most to be identified with the formation of ore.

The mining district of Cripple Creek is co-extensive with an eruptive complex of restricted area, covering about nine square miles and occupying the basal wreck of a Tertiary volcano. It is situated amid the granite of Pike's Peak and consists of a body of breccia, chiefly andesite, which lies upon the worn surface of the granite and fills the deep basin around the volcanic throat. The exact locality of the latter is unknown but the approximate position is inferred from the relations between the crystalline lavas which were the last to be extruded and there is reason to suppose that there were at least two vents, if not more.⁹ The granite is usually referred to as Archean but it is only known for certain that it is of pre-Cambrian age. Evidence obtainable through correlation with the fossil beds of Florissant, 15 miles to the north, warrants the conclusion that the Cripple Creek volcano is of late Eocene age or early Miocene.¹⁰ While andesite breccia is the prevailing rock, the district is especially characterized by later dikes of phonolite as well as nepheline basalt and diabase. The occurrence of rich gold ore is clearly associated with these dikes, and presents a great variety of conditions, structural and petrographic.

A large number of gold veins have been discovered as the result of vigorous explorations during the past fifteen years and a depth of 1,200 ft. has been attained by several mines. The underground workings disclose an intricate network of interlacing goldbearing fractures, which, in different portions of the mining area, are grouped by similarity of strike and they have been found to have a course sympathetic to the dikes, especially the hard phonolite, even when they do not actually run alongside the latter. The veins that were first found near the edge of the breccia have, in many instances, been followed by workings which have penetrated into the underlying granite and it has been proved that the orebodies do persist into this lower geological horizon. The distribution of the richest portions, or 'bonanzas,' of these orebodies presents the same perplexing features as on other gold-fields. A great deal of interesting evidence has, however, been obtainable as a consequence of the extensive development that has followed in the wake of profitable mining.

THE British report from the oilfields in the Baku-district of Russia, is to the effect that steam turbines have lately come into use for driving electric dynamos, and for pumping installations. They have also been tried with some success for driving the drilling rigs, and baling drums in wells. Their chief object, besides a slight economy in steam over the ordinary engine, is their compactness and the comparative ease with which they can be removed from one well to another. Oil motors are used for driving the drilling machinery in prospecting wells, and for pumping installations. These motors must be made to burn crude oil, as kerosene or benzine is too expensive.

Mining in New South Wales.

The mineral output of New South Wales for the year 1906 was valued at \$40,848,120. This is an increase over that for 1905, which previously stood as a record, of \$5,418,655. The aggregate value of all minerals won in this State to the end of 1906 was \$862,801,910. The total number of persons employed in and about the mines of the State during the year is estimated at 42,546, being 3,614 in excess of the number employed in 1905. The gold produced to the end of 1906 amounted to 12,786,638 oz. fine, valued at \$271,570,810. The yield recorded for 1906 was 253,987 oz. fine, valued at \$5,394,330; this was 20,280 oz. fine, and \$430,735 less than in 1905. These figures do not, however, accurately reflect the position of the industry, as gold to the further value of \$800,590 was purchased from the mines within this State, but was not lodged at the mint and could not be included in the official figures for 1906. This gold has, therefore, to be carried forward to the year 1907. The yield was contributed by the established mines, no new find of importance having been recorded during the year. The value of the exports from the silver-lead mines is as follows: Silver, silver-lead, concentrate, ore, etc., \$14,314,865; pig lead, \$5,420; zinc (spelter and concentrate), \$1,464,030, a total value of \$15,784,315. This exceeds the value of the output for 1905 by \$2,194,995, and since the year 1903 the value of the output has increased by \$7,651,435. The value of the output of copper was \$3,947,635, an increase of \$1,310,620 on that of the previous year. The tin and tin ore produced during the year was valued at \$1,278,720, and was in excess of that of the previous year by \$148,170. This output exceeds that of any other year since 1888. The value of the output from the tin fields of the State to the end of 1906 is \$38,722,545, and the number of men employed in this branch of the industry during 1906 was 3,795, an increase of 911 compared with the previous year. The coal raised during 1906 was 7,626,362 tons, valued at \$11,686,135, and exceeded that of the previous year by 994,224 tons and \$1,668,830 in value. These figures constitute a record. In the course of the last two years the output has shown an expansion of 1,606,553 tons. The coal exported during the year amounted to 4,901,760 tons, valued at \$10,381,115. This is much the largest quantity ever dispatched from the State, and shows an increase of 1,183,707 tons, and \$2,461,225 in value on that of the previous year. The number of person engaged in the mining for coal during the year was 14,929, an increase of 910 compared with 1905. The value of the coke manufactured during 1906 was \$553,035, being an increase of \$51,505 on that of the previous year, the industry having benefited largely by the greater activity in metalliferous mining. The value of the other minerals produced during the years was as follows: Alunite, \$23,185; antimony, \$263,225; bismuth, \$28,500; diamonds, \$10,600; iron (from scrap), \$564,240; lime, \$77,865; limestone flux, \$37,315; portland cement, \$642,435; marble, \$7,570; molybdenite, \$23,990; opal, \$282,500; platinum, \$3,115; scheelite, \$38,235; wolfram, \$45,285; sundry minerals, \$13,520.

RUBIES IN BURMA.—The mineral resources of Burma have never been fully developed, but the most valuable at present are rubies, jade, and amber, tin, coal, gold, and marble. The larger part of the world's supply of rubies comes from Burma. These are obtained by mining in the ruby district, which lies 80 miles northeast of Mandalay. The earth is mined and run through pug-mills, the dirt washed away, and the stones collected, inspected, and sorted.

⁹A miniature vent, about 35 ft. wide, can be seen in a railway cutting near Victor. See 'The Cripple Creek Volcano,' by T. A. Rickard. *Trans. Amer. Inst. Min. Eng.*, Vol. XXX, p. 379.

Sinking Through Bad Ground.

Written for the MINING AND SCIENTIFIC PRESS
By F. W. ADGATE.

Timber and concrete have been used recently with success in sinking a shaft on the Mesabi range, near Biwabik, Minnesota. This work is of interest, owing to the extreme difficulties overcome, and the novel application of the pneumatic process to this class of construction. The shaft was sunk for the Syracuse Mining Co. (a subsidiary of the Pickands, Mather & Co.'s holdings), to open up a mine containing a rich deposit of iron ore.

The history of the previous efforts to put down this shaft is a two-year record of disappointment and expenditure of money. The orebody is situated adjacent to, and running under, a lake of considerable size, which surrounds the ore on two sides. Immediately on top of the deposit there is 45 ft. of treacherous quicksand. Owing to the proximity of the lake the ground is saturated with water, and it is difficult to sink a shaft through it by any ordinary process.

The mining company, realizing this, made an arrangement with the patentee of a method of sinking open shafts through water-bearing material, adopting his method and employing him to superintend the work. They began operations in December, 1904. The method consisted of a series of cofferdams driven inside of each other, the first one being sufficiently large to provide space for the other dams inside of it. Eighteen-foot wooden staves or sheet-piles were driven down around two sets of waling timbers, and the excavation started inside the staves.

The first cofferdam being completed, the excavation and pumping was started inside of it. Very slow downward progress was made, however, as the flow of water and sand was too much for the pumps. The next set of staves was started, but landed on top of a bed of large boulders and could not be forced down. By this time four No. 10 Cameron pumps could not handle the inflow of sand and water, and it became apparent that the work could not be successfully accomplished by this method. After a four months' trial the mining company decided to stop all operations at this point, and to sink a shaft at a point some two hundred feet farther south. Here the overburden is 50 ft. greater, but the chance of avoiding the boulders was considered much better.

The mining plant previously installed was accordingly moved to the proposed site. At the new site, the company with their own force sank a large timber shaft to the quicksand (about 50 ft.) by the method commonly employed on the Mesabi range. This consists of suspending sets of timber, about three feet apart, from the surface. As the excavation proceeds 2 by 10 in. planks, 4 ft. long, are slipped in back of these timbers, forming a comparatively tight wall to keep out the soil. Each course of waling timbers, or each set as it is locally called, is suspended from the set of timbers immediately above it by 1½-in. bolts, the top set of timbers in turn being connected in a like manner to large round timbers, called bearing timbers, on the surface, spanning the excavation and carrying the weight of the shaft until it rests on the bottom.

From the surface of the quicksand it was the intention to drive steel sheet-piling to bedrock. The shaft was accordingly built large enough to permit a steel sheet-pile cofferdam at the bottom of, and inside, the timber shaft. Work was started on driving the steel sheet-piling in November, 1905, and continued until the following spring. The piling was driven from an ordinary pile-driver derrick, which rested on the timber shaft at

the surface, and was sent home by means of a special follower designed by the manufacturers of the steel piling. A 3,000-lb. hammer was used, and at one period of the work a water jet was also employed to assist the work of the hammer. The piles were driven very hard and were of the heaviest section turned out by the manufacturers.

After the pile cofferdam was completed, a No. 10 Cameron pump was installed and the excavation started inside the steel piling, waling pieces and struts being introduced about ever three feet as the work progressed, to keep the piles in place. The excavating was accomplished without much difficulty to a point about 20 ft. below the top of the piles. Below this point it proceeded very slowly. After taking out a few feet of material the quicksand would suddenly start to boil up from the bottom, accompanied by a corresponding movement of the material on the outside of the shaft. This distorted the timber shaft and cracked its timbers.

It became evident to those in charge that there must be a bad leak or break in the steel sheet-piling, and means were at once adopted to overcome this difficulty. A crib of 10 by 10 in. timbers, 3 ft. high, was built at the bottom of the excavation inside the shaft, the intention being to load this crib and force it down with the hope that it would overlap the leak or break in the piling, and that then work could be prosecuted successfully. The crib was forced down a few feet and then stuck and very little, if anything, was gained by the scheme. In the meantime each period of excavation was followed by an upward boiling of the quicksand at the bottom. The material around the outside of the shaft settled away, leaving the upper part of the shaft exposed. Hay, straw, etc., were placed outside the shaft with the hope that at each settlement of the sand, this material would be carried down outside the steel piling and ultimately stop the leak in it.

At this stage it became necessary to support the timber shaft, as it had broken away from the bearing timbers at the surface, and was settling down and telescoping the steel cofferdam. This was accomplished by stretching railroad rails and timbers across the top of the cofferdam and under one of the sets of timber of the wooden shaft, allowing the timber shaft to take a bearing on them. Pumping was then resumed and pieces of sheet iron were forced down alongside the sheet-piles and every effort was made to find and stop the holes where the quicksand was entering the shaft. As a last resort grout was pumped down to bedrock through a two-inch pipe, it being withdrawn and moved frequently. This was allowed time to harden and the excavation was resumed. After advancing a few feet, the sand and water broke in from the bottom and boiled up as usual. On the first of August the Mining Company decided that the shaft could not be sunk by ordinary methods, and they then called upon the Foundation Company, of New York, to devise plans and contract to sink the shaft far enough into the bedrock to make a watertight joint with the rock.

The Foundation Company began operations early in October, 1906. Their plan was to line the upper or timber part of the old shaft with reinforced concrete, leaving a shaft 13 ft. 6 in. by 6 ft. 1 in. and having two hoisting compartments 4 ft. 6 in. by 6 ft. 1 in. at each end and one compartment 6 ft. 1 in. by 3 ft. 6 in. at the centre for a pipe and ladder-way. A concrete roof was then to be built on the upper ends of the steel sheet-piling. The material inside the steel sheet-piling was to be excavated and the shaft below the roof lined with 10 by 12 in. timbers, all to be done under air pressure. The timber was to be thoroughly caulked, course by course, until a joint was made between the bottom timber and the lode.

Provision was made to suspend the entire weight of the timber lining from the roof until it rested on bedrock.

It was then decided to pump out the shaft as low as it had been excavated, about 18 ft. below the tops of the steel sheet-piles, and timber from that point up to the point where the concrete roof was to go in; next, to construct the roof and line the old timber shaft with concrete from the top of the roof to the surface of the ground. On account of the dangerous condition of the timber shaft and because of the fact that it had been strengthened from time to time with cross-braces, which left but little working room in the shaft, this order of operations was found to be impracticable. It was evident that the first thing that must be done was to secure and make safe the old timber shaft. Work was immediately begun on this, the first thing done being to transfer the weight of the shaft from the tops of the sheet-piles to the surface of the ground. This was accomplished by putting in some extra heavy bearing timbers 60 ft. long across the top of the shaft at the surface. The old shaft was connected by twelve 1½-in. bolts to these timbers. The cross-timbers and rails on which the shaft formerly rested were then cut out and the shaft was again suspended from the surface.

A space two feet long was now cleared of bracing, broken struts, etc., at the bottom of the timber shaft and a concrete form started to line the shaft. Great care had to be taken in cutting out and shifting the struts and braces to make room for the concrete, which was deposited in sections about two feet high. The timber in the shaft was cracking and moving a good deal while this work was being done, and it was hard to get men to stay in the shaft. A few of the cross-braces were concreted in, and after the concrete had set they were cut out and the ends dug out of the concrete, the resulting space being filled with concrete. This work necessarily proceeded very slowly, temporary braces and jacks being used and continually shifted. Then, too, the scarcity and poor quality of the only labor available tended to make the work go slowly. On November 9, the concrete lining had reached a point 10 ft. from the top of the shaft and it was then considered to be in a perfectly safe condition.

Horizontal reinforcing rods ½-in. square, spaced 12 in. centre to centre, vertically, were used in the concrete lining. A recess 6 by 18 in. was left one foot from the bottom of the side and end walls to permit the concrete roof to be keyed into them. The shaft was then pumped out to the sand, about 18 ft. below the bottom of the proposed concrete roof, and the work of lining the shaft from this point to the bottom of the roof with 10 by 12-in. timbers was commenced. This also was a ticklish piece of work, as the bracing then in the shaft at this point had to be removed and solid timbering substituted. The sides and ends of the shaft were lined, starting from the sand, one course or set of timbers resting immediately on the one below it. The joints between the different sets were well caulked and hawsed with oakum.

The shaft was braced transversely by two solid walls of 6 by 12-in. timbers, each placed 1 ft. 9 in. from the centre of the shaft. These also served as walls and subdivided the shaft into three chambers, thus: A skid-way at each end 4 ft. 6 in. by 6 ft. 1 in. and a pipe and ladder-way 6 ft. 1 in. by 3 ft. 6 in. at the centre. In the four corners of the shaft were 3½ by 3½ by ½-in. angles bolted to each set. These secured and braced the ends of the timbers in a most satisfactory manner. The form for the roof was then suspended from 12 by 12-in. timbers extending across the finished concrete walls of the shaft by twelve 1½-in. bolts, and work on the concrete roof was started. The roof consisted of a slab of concrete 5 ft. thick, the size of the shaft, and extending into the recess

left when the lining was built, as before mentioned. The roof was heavily reinforced with 1½-in. steel bars running horizontally in both directions about six inches. Eight 1½-in. steel bolts were built into the roof, and after the roof had hardened sufficiently, the weight of the timbering below the roof, which was built on the sand bottom, was transferred to these bolts so the sand could be excavated below the timber without danger of settlement.

A section of 48 in. air-shaft had also been built into the roof, and when the concrete had attained sufficient hardness this shaft was continued up to a point 30 ft. above the roof. A Moran air-lock was then connected to the top of the air-shaft and air was turned into the shaft on December 18, 1906.

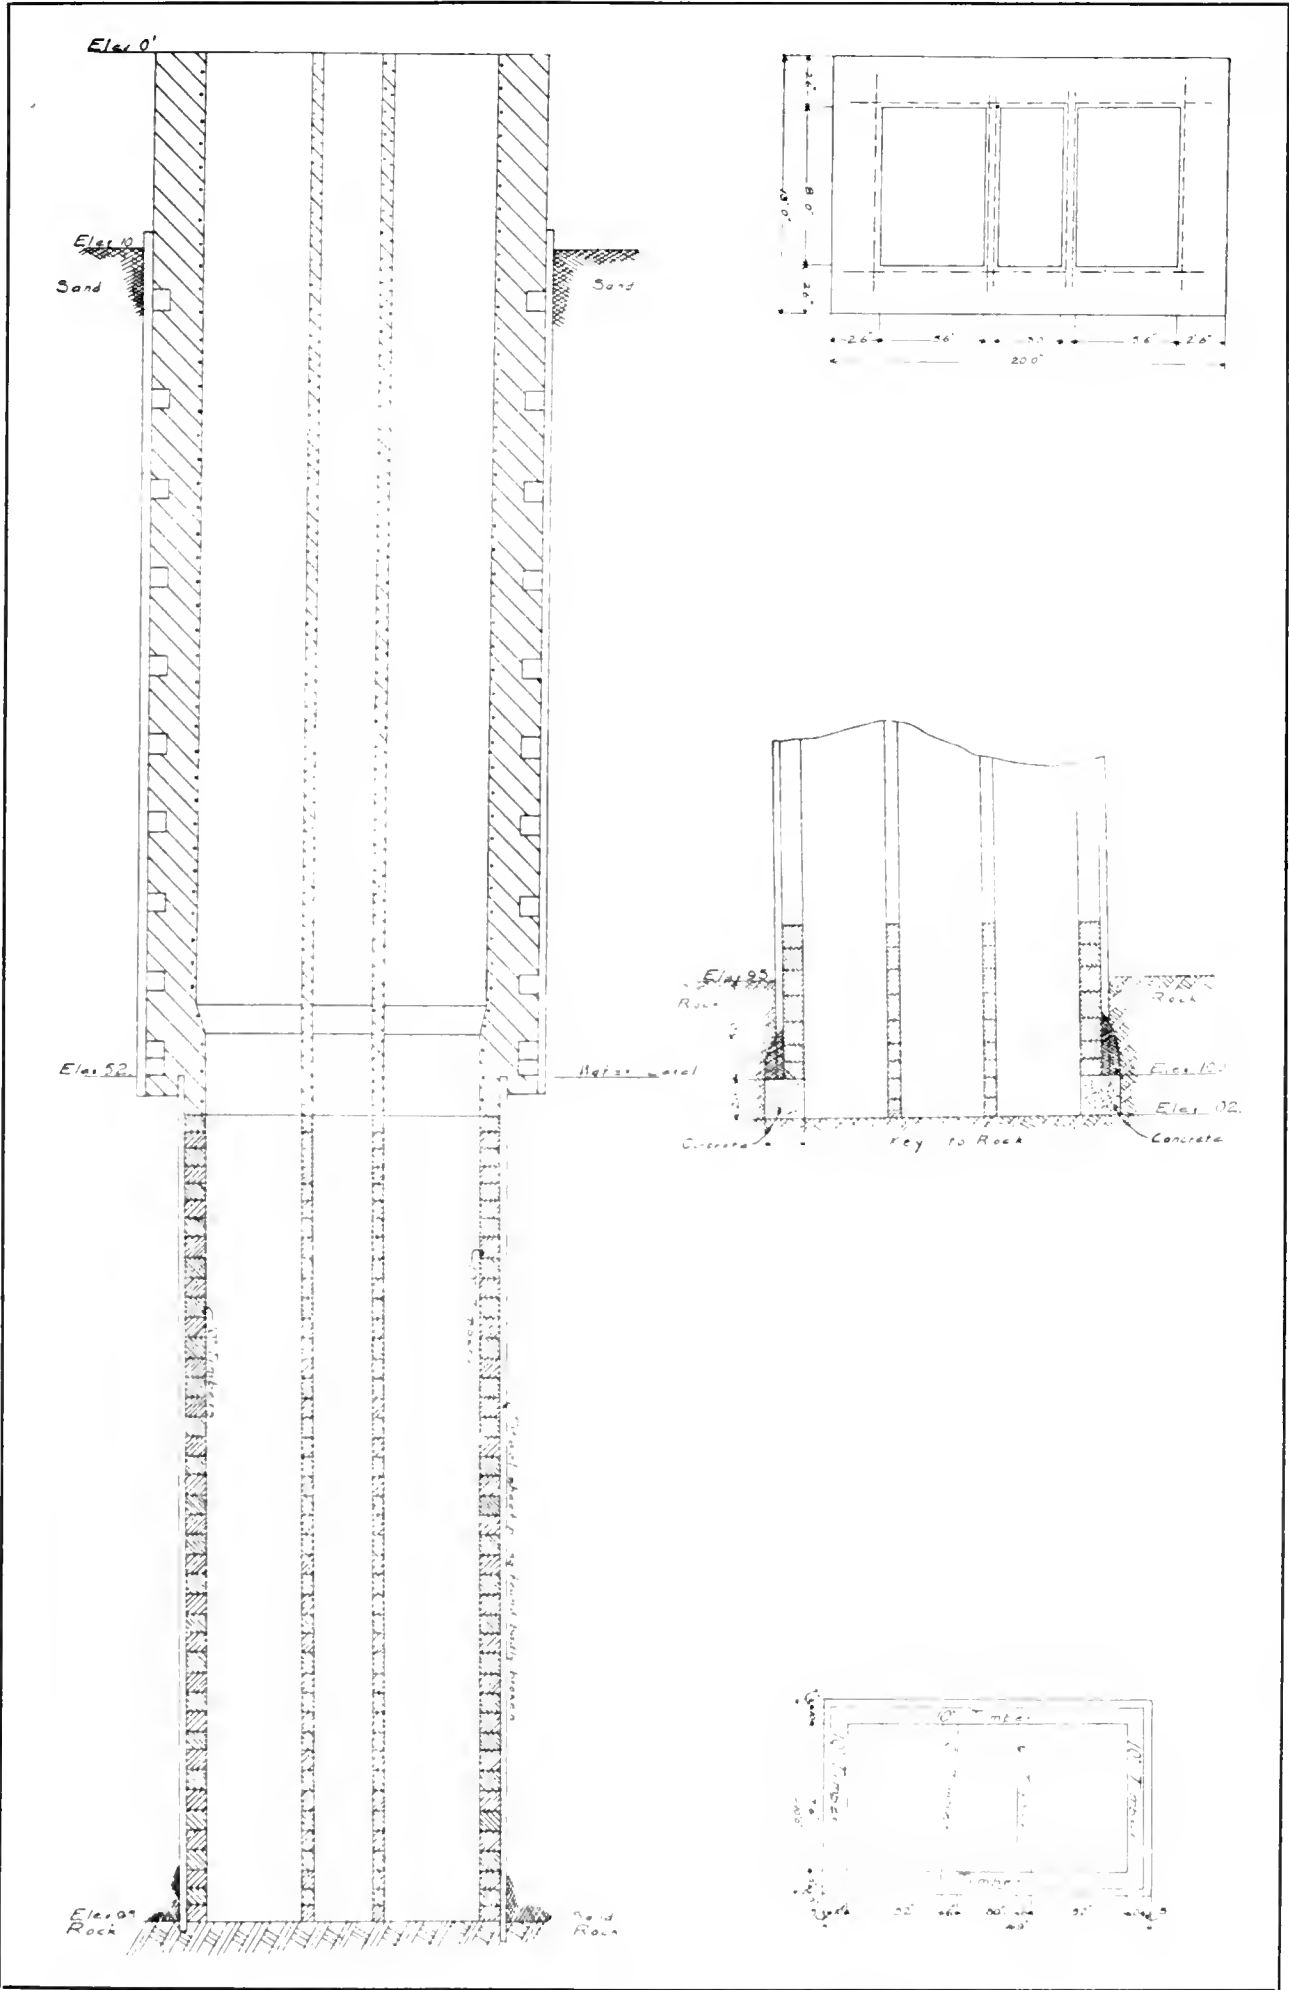

The work of excavating the shaft and lining the steel sheet-piles was carried on rapidly for 12 ft., although the old crib or timber lining, previously mentioned, had to be cut out and sent to the surface. All the timber lining was lowered through the air-lock and shafts from the surface, where it had previously been framed. As each stick was put in place it was suspended from the timber above it by 2½ by ½ in. iron straps 24 in. long fastened to each timber by two 7 by ¾ in. lag-screws. After ten courses of timber were suspended in this manner, an iron strap of the same dimensions (but long enough to engage ten sticks of timber instead of one), was fastened to the wall in the same manner and the upper end of the roof-bolt as a necessary precaution.

The size of the finished shaft inside of the steel sheet-piling was somewhat smaller than was anticipated, and for the first 25 ft. of this work there was a space of from 3 to 6 in. between the timber lining and the steel piling. This space was filled with rich concrete. As this had to be suspended from the roof as well as the timbers, and had to be put in from the bottom instead of the top, it was found difficult. However, the general line of the steel piling slanted toward the centre of the shaft and it was not long before the space enclosed by the piling was none too large to receive the timber lining.

At this point, 12 ft. down, it was discovered that four of the sheet-piles had landed on a boulder so as to be deflected from their course and, as they were further driven, they curled up inside the shaft in almost true circles of from 4 to 6 ft. diam. These were cut off with pneumatic tools and sinking was resumed. On account of the large space left open for the escape of air, caused by cutting out these four piles, and the peculiar nature of the ground, great difficulty was experienced from this point downward to bedrock. It was almost impossible to keep the water and quicksand low enough to get in a set of timbers. In a good many cases this could only be accomplished by the aid of jacks and an air-jet.

More steel sheet-piles were encountered as sinking progressed, piles that had broken away from the general line of the piling and had been forced into the shaft-area. Some of them had to be cut several times as the excavating and timbering proceeded. In all 143 cuts were made in the steel sheet-piles. This of course was slow work as a good many of them had to be cut 14 in. under the surface of the sand and water to allow for placing the timbers. The work was further retarded by a fire caused by the flame of a miner's candle, and by the breaking down of an air-compressor, both happening at different times, and it was not until March 12, 1907, that the bedrock was reached.

It was the intention of the contractor to stop the shaft at bedrock and, after making a tight joint with the same, turn it over to the mining company, but in reaching the bedrock it was found to be so badly broken up and seamy that it was finally decided to carry the excavation under air into the rock itself. After going

Sinking Through Bad Ground.

into the rock 12 ft., it was thought best to stop further sinking under air-pressure and finish the shaft in the open. Accordingly a tight joint was made with bedrock and air was taken off on May 10. The walls of the shaft were found to be tight and in good condition. Very little water came in, and that only in the centre of the rock bottom.

The contractors had a complete equipment of modern plant for the work, consisting of air-compressors, pneumatic tools, electric light plant, etc., besides other plant devices of which they control the patents. Very little, if any, headway could have been accomplished without these aids. The Syracuse Mining Co. was represented by C. H. Munger, general manager, and the work was done under the direction of F. W. Adgate, superintendent for the Foundation Company.

WELSH MANUFACTURE OF FUEL.—The manufacture of patent fuel is an important industry in South Wales, especially at the leading seaport towns Cardiff, Swansea, and Newport. Large quantities are exported every week from these ports, and the demand for this product is greatly on the increase. Therefore any improvement in its manufacture creates a wide interest. The old method of making the fuel into briquettes was the blending of fine particles of small coal with about 8 to 10% of pitch under steam heat and subjecting it to great compression. This has been the mode of manufacture since the inception of the industry in Wales, but now a revolution in the manufacture is at hand and the future of the trade seems to be encouraging. Patent rights for the new method have been secured in every country producing coal and manufacturing briquettes. The basis of the new manufacture is a combination plant, that admits of the use of tar instead of pitch, with heat supplied largely by means of furnace-gases instead of steam. The price of tar is about \$5.60 per ton against pitch at \$8.52 per ton, while only 5% of tar is used against 9% of pitch. The use of pitch involves great labor in handling, being a solid when not under manufacture, while tar, being always liquid, can be pumped or piped practically automatically all the way from the gas-works to the point of manufacture in the fuel works. As tar runs thinner than pitch, it coats practically every particle of coal, the mixing arrangements being as nearly perfect as possible; this affords a binder quite unequaled for the purpose. The less quantity of the binder and consequent greater compression, the less chance of expansion in the briquette under the climatic conditions to which this class of fuel is always subject. An important gain of the new process will be the distillation of tar from various oils. In the case of bituminous and semi-bituminous coals the heating process takes sufficient of the gases away to render the fuel practically smokeless. Arrangements are being made to erect a large plant at Cardiff, and also in the various coal producing districts. The new product has been supplied on trial for some time to several heat-consuming concerns with eminently satisfactory results. As a railroad fuel, especially for running express trains, it is considered by far the best of all fuels now in the market, taking efficiency and economy into account. It is claimed that the new fuel is superior to that made by the old method from every point of consideration—emitting less smoke, being less brittle, and showing greater tensile strength. Placing it on the same level in the matter of quality, the gain in manufacture, altogether apart from the utilization of by-products, the new fuel can be made at 59c. per ton cheaper than fuel made under the old conditions.

Coal Mining in California.

The United States Geological Survey, through E. W. Parker, fuel expert, reports that the total production of coal in California in 1906 was 25,290 short tons, having a spot value of \$60,710.

The large and rapid increase in the production of petroleum in California, which has grown from 4,324,484 bbl. in 1900, to 33,098,598 bbl. in 1906, and the use of this product as fuel in locomotives and in factories in the State has resulted in the suspension of operations at several of the lignite-producing properties, and in consequence the returns for 1906 show a decline in production from 77,050 short tons in 1905 to 25,290 tons in 1906, a decrease of 51,760 tons, or 67.5%. The decrease in value is in even greater proportion—from \$382,725 to \$60,710—a loss of \$322,015, or 84%; but this apparently large decrease in value was due to the fact that in 1905, as in 1904, the value of the product was seemingly large because the price of briquetted fuel at Stockton was based on the manufactured product and not on the raw fuel.

The plant at Stockton was burned in the fall of 1905 and has not been rebuilt. The value in 1906 is for the raw fuel only, as the briquetting plants of the Western Fuel Co. at Oakland, and of the Pittsburg Coal Mining Co. at Antioch, were operated on screening from the coal yards in San Francisco, and not from raw coal mined in the State.

A new briquetting plant that is now being erected at Stege by the United States Briquetting Co. is designed to combine peat with heavy California oil. The sample briquettes heretofore made are composed of 50% peat and 50% crude oil, and are intended for use as domestic fuel. The briquetting plant of the Ajax Coal Co. of San Francisco, which is mentioned in the report for 1905, was destroyed by the earthquake and fire of April, 1906, and has not been rebuilt.

The coal produced in California is lignitic or sub-bituminous and is mined in a number of widely separated fields. The chief mines are in the Mount Diablo field, in Contra Costa county, and the Corral Hollow field, in Alameda county, but small amounts are mined in Kern, Monterey, Riverside, and Siskiyou counties. Two other areas which have produced small amounts of coal are the Ione field, in Amador, and a small area near Elsinore, in Riverside county. Butte, Del Norte, Orange, Fresno, San Diego, and other counties have also produced small amounts, and some prospecting has been done in Fresno, Mendocino, Placer, Orange, and Trinity counties, but little encouragement is held out for any extensive development outside of the two fields now exploited.

The records of the State Mining Bureau of California show a production of coal in the State as early as 1861. It was at that time one of the 15 coal-producing States. In the late sixties and seventies the annual production of California exceeded 100,000 tons, and reached a maximum of 237,000 tons in 1880. Since 1881 the production has been rather irregular, having been largely influenced by the imports of coal from Australia and British Columbia. The receipts of Australian coal have depended principally on the production of wheat and its shipments from the Pacific coast. Vessels bringing Australian coal as return cargoes have offered very low freight rates.

OXYGEN AND ACETYLENE burning in a blowpipe produce the hottest known combustion flame. The temperature is estimated at 6,300° F., 1,200° higher than the oxy-hydrogen flame and nearly equal to that of the electric arc.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

CRUSHER.—No. 859,348; Thomas L. Sturtevant, Quincy, and Thomas J. Sturtevant, Wellesley, Mass., assignors to Sturtevant Mill Company, Portland, Me., a Corporation of Maine.

In a crusher, an operating lever having a pair of recesses, a pair of dust-proof box bearings having closed ends and mounted in said recesses, means for removably holding said bearings in position in said recesses, and a roller journaled in said bearings, the crusher frame consisting of relatively thin side plates, a head block or front cross beam, and a rear cross beam overhanging said side plates laterally and having flanges arranged within said side plates and firmly attached thereto so as to brace said side plates, combined with a driving shaft, the bearings of which are supported by said rear cross beam whereby said relatively thin side plates are relieved from the direct strain of the driving shaft, and a vibrating crushing jaw operated from said driving shaft.

COMPOUND DUMPING-HINGE AND AUTOMATIC DOOR-BAR FOR ORE-CARS.—No. 860,817; Walter C. Matteson, Stockton, California.

In a device of the character described a compound hinge disposed between the turn-table and body of an ore-car, and straight bars pivotally mounted to said hinge, and provided with hooks adapted to engage with the door catches of the car.

METHOD OF DEPOSITING AND RECOVERING METALS.—No. 860,661; Wilbur A. Hendryx, Denver, Colorado.

The method of depositing and recovering metals, which consists in passing a stream of metal-bearing solution through a granular precipitating agent, agitating said precipitating agent and thereby separating the metallic deposit, and providing clean surfaces for further deposition, transporting the separated deposit by said stream, and collecting the deposit.

COAL-MINING DRILL POST.—No. 858,217; Paul Rommes, Pittsburg, Kansas.

In a coal-drilling machine, a supporting post, means for anchoring the same at its upper and lower ends, an adjustable arm carried by said post, brackets slidably mounted on said arm, and a threaded box and auger shaft supported by said brackets.

PROCESS OF PRODUCING FERROSILICON.—No. 861,224; Edgar F. Price, Niagara Falls, New York.

The process of producing ferrosilicon by smelting an electrically conductive charge of a silicon compound, carbon, and a source of iron, which consists in establishing an electric arc within the charge, surrounding the zone of reduction, and protecting the electrodes from the oxidizing and cooling effect of the atmosphere by a considerable body of the charge, and maintaining between the electrodes the minimum potential difference requisite to effect reduction, thereby substantially preventing loss of electric current by leakage through the charge and heat radiation.

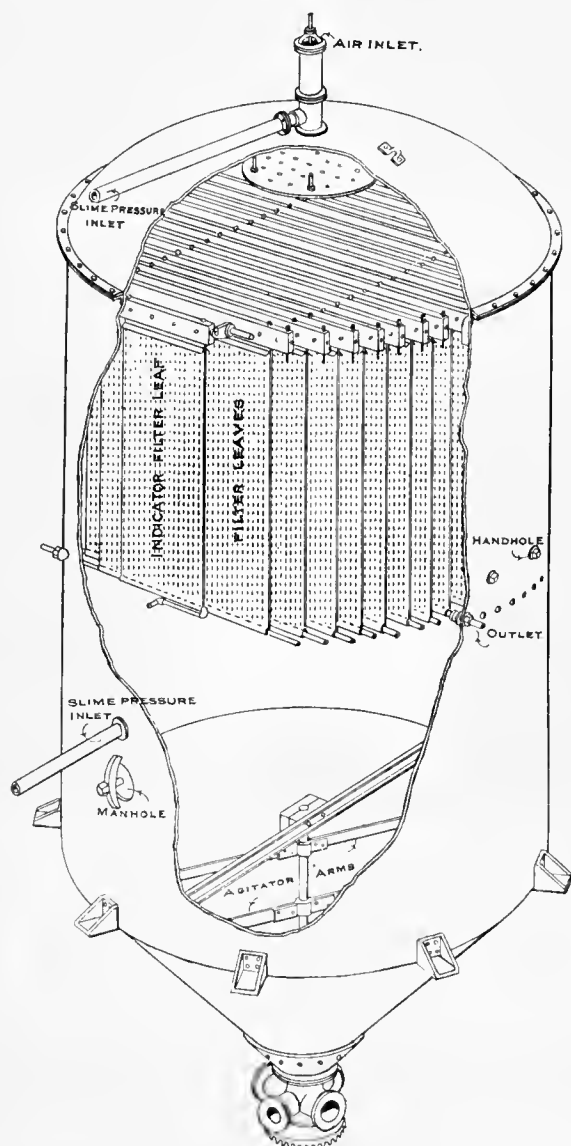

MINERS' CANDLESTICK.—No. 859,672; Henry Laukka, Virginia, Minn., assigner to Otto A. Poirier, Virginia, Minnesota.

A miners' candlestick comprising a shank having a handle at one end and a point on the other end, a candle holder having an angular stem formed with a polygonal portion engaging a correspondingly shaped seat on the said shank, and a spring connected to the shank, and bearing on the said stem to hold the stem to its seat.

The Blaisdell Pressure Filter.

The accompanying cut shows the Blaisdell Pressure Filter, for the treatment of slime or the fine portion of mill-pulp. The filter consists of three parts; a series of filter leaves; a pressure cylinder, and pumps for vacuum, slime, water, and solution. The illustration shows the pressure cylinder and the filter leaves contained within it. This cylinder is of steel, designed to withstand a pressure of 50 lb. per sq. in. In erecting, this cylinder is placed on end and is supported by iron columns or masonry. The leaves are suspended in the cylinder, each leaf consisting of a series of non-porous columns, vertically grooved with narrow drainage channels, covered on all sides with canvas. The outlet from the leaf is at the lowest point. The charging of the cylinder is accomplished from a slime-storage tank by gravity, and the pressure is maintained by a small pump, another small centrifugal pump being required to maintain the pressure of the solution and wash-water. The process

BLAISDELL PRESSURE FILTER.

of dewatering mill-pulp is continuous. Slime thickened in cone classifiers is fed into the cylinder, and, at a pressure of 25 to 50 lb. on the liquid in the cylinder, the clear water or solution is rapidly forced into the interior of the filter leaves, the slime remaining as a cake on the outside. The process is carried on without interrupting the flow of slime to the pressure cylinder. As soon as a cake of sufficient thickness is formed, clear water under a greater pressure than exists within the cylinder is admitted into the interior of the leaves in groups, causing the cake to fall through the slime to the bottom of the cylinder, whence it is discharged from time to time, and forced to the agitation vats.

In recovering gold-bearing cyanide solution from slime,

the clear solution is filtered into the leaves and goes to the precipitation vats. As soon as a cake about two inches thick has formed on the leaves, the supply of slime is cut off and the surplus returned to the sump-tank. The pressure cylinder is then filled with a wash solution, which is forced through the leaves. While transfers of liquids are being made, the cake is held in place by a partial vacuum. To remove the valueless cake from the filter, clear water at a low pressure is admitted to the interior of the leaves, causing the cake to fall to the bottom of the cylinder, where it is discharged. This company is building one of these filters with a capacity of 500 tons of slime per day.

Catalogues Received.

THE DRILL HOLE is the title of a new magazine issued monthly by the CYCLONE DRILL CO. of Orrville, Ohio. The first issue promises well.

THE BUFFALO STEAM PUMP CO., of Buffalo, N. Y., has published Catalogue No. 187, on steam and power pumps and centrifugal and turbine pumps.

THE AMERICAN ELECTRIC FURNACE CO., of New York City, has issued Bulletin No. 1, describing its induction furnace, for the production of steel by electricity.

THE COLORADO IRON WORKS CO. of Denver, has issued Catalogue No. 6—C on 'Stamp Milling Machinery.' This is an attractive catalogue, containing a brief description of the amalgamation process and an account of machinery and appliances used therein.

THE FORT WAYNE ELECTRIC WORKS, of Fort Wayne, Ind., sends us Bulletins No. 1,094, 1,095, and 1,096, concerning 'Belted Direct-Current Generators, Type LF;' 'Enclosed Alternating-Current Multiple Arc Lamps, 104-volt, Type A. C. M., Form C;' and 'Type A Transformers.'

Commercial Paragraphs.

THE COMPRESSED AIR MACHINERY CO. recently shipped two Word Brothers' drill makers and sharpeners to Goteborg, Sweden.

Adolph Hirsch, of the DIAMOND DRILL CARBON CO., of New York, has gone to Europe. From there he will go to Bahia, in Brazil.

THE KELLY FILTER PRESS CO. has been incorporated exactly a year and has made a fine start. Two 50-ton units of this filter has been sold.

THE UTAH MINING MACHINERY & SUPPLY CO., of Salt Lake City, for which J. E. Galigher is manager, is doing a good business on Callow screens for use in mills. This company has shipped these screens to every known mining country in the world. The screen is covered by patents in this as well as foreign countries.

Publications Received.

'The Forest Service.' What it is and how it deals with forest problems. Circular No. 36, U. S. Dept. of Agriculture.

'The Ballarat East Gold-Field,' No. 4, by J. W. Gregory. Memoirs of the Geological Survey of Victoria. A valuable report dealing with the celebrated 'indicators' of Ballarat.

'A Method for Calculating Steam Power Plant Economy,' by C. R. Weymouth. This deals with engine and boiler efficiency, costs, and economy, and is published by Charles C. Moore & Co. of San Francisco.

Dividend.

On August 5, the Bunker Hill & Sullivan Mining & Concentrating Company paid dividend No. 119 of \$180,000. This makes the amount of dividends paid since January 1, \$1,440,000, and the total to date \$9,306,000.

Editorial.

DREDGING FOR GOLD is flourishing in regions as far apart and as unlike as possible. In the frozen lands of Alaska there is an increasing application of this form of mining and in Burma the results obtained from three dredges are so good that a fourth is under construction. We hope to see a further development in this branch of the mining industry.

THE OUTPUT OF GOLD from Rhodesia is increasing, the past half-year making a record of 292,000 ounces as against 262,000 and 197,000 ounces in the corresponding periods of 1906 and 1905 respectively. But this increase is due not to expansion of the larger mines, but almost wholly to small parties of tributers and local syndicates. The British investor finds the returns discouraging, because the companies of large capital are credited with a shrinking production.

OUR READERS will be glad to read the article on 'Gold Mining in Egypt' by Mr. C. S. Herzig, an engineer familiar with most of the goldfields of the world. It appears that "in the days of old Rameses" they dug for gold sufficiently well not to leave any rich pickings for the prospectors of today. The story told by Mr. Herzig emphasizes once more the fact that with forced labor you can work more cheaply than with up-to-date machinery and the expensive skilled labor of these days. Not that we want to see convicts or slaves in our mines; human liberty and the pursuit of happiness by all the sons of men are worth more than any gold mine. The moral is: Every *antiqua* is not a bonanza.

WE SHAKE HANDS with the editor of *The Bee*, one of the oldest papers in California. It appears that our contemporary has said some true, and therefore unpleasant, things about the Western Federation of Miners, and thereupon the threat has been made to boycott the paper. Not long ago *The Bee* got into trouble for fearless criticism of the Mine Operators Association in Colorado, finding fault with their disregard of law and defiance of government during the bad days of 1903 and 1904. As we also have found ourselves called upon to oppose lawlessness on both sides of an industrial vendetta and have therefore become unpopular among a few extremists, we sympathize with our contemporary and wish it the best of luck in the good work of independent journalism. It is the function of newspapers to form, and not to follow, public opinion; to be leaders and not servile followers of the crowd; to express the ideas and hopes of the intelligent minority, not to echo the windy clamor of the thoughtless majority. May *The Bee* prosper, and whether it feels called upon to make honey or

to sting, may both functions be used in the best interests of good citizenship.

THE JULY BULLETIN of the American Institute of Mining Engineers possesses a mortuary interest by reason of the large number of biographical notices of members deceased in 1906. Some of the engineers whose lives are briefly recorded were widely known and respected. If the mention of their names recalls a pleasant memory, an inspiring example, or a pathetic warning, it will have served a good purpose. Among them are W. A. Akers, T. S. Austin, Edgar V. Bensusan, Horace F. Brown, R. G. Hart, George L. Keener, W. S. Keyes, Stanley H. Pearce, George H. Robinson, John Stanton, Edward G. Stoiber, John P. Wetherill. In addition, two non-American, but hardly foreign, members of celebrity were Charles Lowthian Bell (England) and Richard J. Seddon (New Zealand). No single reader is likely to go through the above list without feeling a cloud passing across his horizon and to some of the travelers of the profession, possessing a wide acquaintance, this group of vanished presences will seem a great company. Technical skill, inventive genius, fine power of application, good mining judgment, metallurgical insight, business energy, inextinguishable cheerfulness, probity of purpose, and sterling character are all here typified. Nor have they been wasted. Most of these men had accomplished something; some of them have left a good example. And among so many good men we dare to pick out one name and record once more our heartfelt respect for a man of sterling honesty, good sense, and sincerity of purpose—JOHN STANTON. He had the qualities most necessary, and too often lacking, in an era of drunken prosperity and unrestrained industrial activity. The memory of such a man bears no sting; it is a bugle call in the mêlée of life.

IN MEXICO the abandoned mine workings of the Indians and Spaniards are termed *antiguas*. Modern days have seen several attempts to rehabilitate such old mines in different parts of the world. There was the Esperitu Santo in Darien where E. R. Woakes made a reputation, the great silver mines of Potosi that Arthur F. Wendt reopened, the ancient diggings of Rhodesia which lured British promoters, and the pits that led to the development of the Kolar goldfield in India. But of all romantic possibilities in mining the slag-heaps of Burma are the most attractive. According to the reports of Bewick, Moreing & Co. and Sulman & Picard, the Baudwen mines were formerly in Chinese territory, and were known as "the great silver mine situated between Pekin and Mandalay." They were worked in the fifth century, attaining a maximum production a thousand years later. The Chinese extracted the silver and allowed most of the lead to run into the slag, heaps of which are scattered over a distance of three miles in the valley of the Sterne river, a tributary of the Nam Tu. The slag has been sampled carefully and is said to assay 47 per cent in lead, 16 per cent in zinc, and 2½ ounces of silver per ton. It is estimated that 110,000 tons of such stuff is available. Smelter superintendents will smack

their lips at the idea of tackling such a sweet mass of ancient slag. It is believed that the slag can be treated for \$30 per ton, extracting 90 per cent of the lead, and that there is a profit in these dumps of about \$1,250,000. We shall be curious to see how the enterprise succeeds. It is supposed that the old mine workings do not extend below the water-level and from the pillars remaining in places there is reason to expect ore containing silver, lead, zinc, and copper—possibly an excessive metallurgical multiplicity. One pit is 800 feet in diameter and 500 feet "from the top of the hill"—a vague statement, but enough to indicate that the ancient diggers dug a goodly hole. The tropical bush has overgrown everything and accurate information will not be obtainable until the ground is cleared. This work awaits the completion of a railway 45 miles long, for the iron horse is the only sure conqueror of the waste places of the earth. This Burmese undertaking has many points of interest and we hope to obtain details at a later date.

Crystals and Water in Veins.

WALDEMAR LINDGREN has earned the goodwill of mining engineers by more than one illuminating paper upon the great subject of ore deposition and their sense of personal gratitude will be heightened by his last important contribution to geological literature. We refer to an essay on 'The Relation of Ore-Deposition to Physical Conditions', the larger part of which we publish elsewhere in this issue. It was read before the International Geological Congress in Mexico last year and subsequently published in *Economic Geology*, an excellent magazine. Many points of interest are touched upon; for instance, the occurrence of large cavities lined with a crystalline growth has puzzled miners, who know that open spaces underground tend to close, and physicists, who are aware that the tremendous pressure at great depth causes rocks to undergo deformation. The incompressibility of water has been an argument for the possibility of crevices existing deep down and the hydrostatic pressure due to gravity has been credited as a cause in keeping fissures open. Finally, a more scientific explanation has been sought in the power of crystalline growth to force the walls of veins apart. None of these suffice, but recently Mr. L. C. Gratton has hit on a happier idea, namely, that the tension of an upwelling magma could open crevices and allow of crystallization of minerals dissolved in magmatic waters. These would be allied in character to the solutions forming pegmatite dikes. Thus they recall the idea we associate with Mr. J. E. Spurr's 'alaskite', a rock consisting of quartz and alkali feldspar, deposited from the residual silicious solutions, serving thereby as a link to connect quartz veins and pegmatite dikes. In this way the gold-bearing quartz lode becomes the last phase of differentiation from a magma; it is built from the attenuated solution that is left over after the basic elements have separated and solidified. Another suggestion worthy of mention is one made by Arthur L. Collins, only a few months before his assassination, when he and the writer were

admiring the beautiful crystals of calcite on quartz as seen in specimens from the Smuggler-Union mine at Telluride, Colorado. He suggested that the exquisite transparency of these crystals argued an extremely slow process of crystallization, that is, the maintenance of uniform conditions over a long period.

Undoubtedly the recognition of zones of change, or successive depths at which certain conditions obtain, has done much to promote an intelligent understanding of ore deposits. Mr. Lindgren now advances the study of the subject by actual tabulation of the minerals characterizing these successive zones, which are roughly described as superficial, shallow, and deep. The uppermost horizon is one of great economic importance by reason of the changes induced in the metallurgical complexion of orebodies; the intermediate zone is that in which most of man's digging for the metals is now in progress; it is the zone concerning which geological evidence is most nearly satisfactory; while the deep region is one that extends indefinitely downward to the barysphere or *erige tiefe*, it is brought within the sphere of human observation by erosion, and includes many lodes of gold and silver ore formed in pre-Cambrian time. How temperature and pressure have influenced the metasomatic development of minerals, their decomposition, substitution, and re-arrangement, is told clearly by Mr. Lindgren. We shall not try to add to his observations, which are summarized in a few crisp sentences. But one factor in the distribution of ore in lodes may be mentioned, and emphasized. We refer to the water zone.

It is pretty clearly ascertained, especially among mining engineers and others in daily touch with underground operations, that there is a definite layer of water, the top of which has long been known as the 'water-level.' The bottom of this zone of water has not been recognized, simply because the sinking of shafts tends artificially to depress it; for the lateral workings of a mine, by draining an adjacent area, cause the shaft to serve as a sump or well. Miners know that at a certain level they get below the maximum seepage and in large mines the pumps are placed so as to 'take up' that water. This horizon will vary just as the top of the water varies, with topography, climate, altitude, rock structure, and other conditions modifying the amount of water at the surface and penetration of it into the mine workings, that is, the lode or vein being exploited. Below the water zone the lode becomes dry, even dusty, so as to imperil the health of miners. There is no uniformity in the depth to which this water (which is derived from the surface) penetrates, for a vein may be dry when a crossing fault-fissure is full of water; nevertheless, we have ample reason to believe that the body of water penetrated by mines has a bottom, in most cases reached within 2,000 feet from the present surface, and that below it the rock is dry enough at least not to afford a vehicle for the circulation of mineral substances. Below this again we encounter the up-welling magmatic waters and thermal solutions representing a phase of igneous activity and volcanic unrest. The whole trend of recent theory is to subordinate the importance of meteoric

waters (waters due to rain and snow at the surface) in the original deposition of ore and to restrict them to the secondary but immensely important work of concentration, re-distribution, and oxidation, above and just below the water-level. Gradually the agency of magmatic waters has been forced upon the attention of students, by Vogt, Kemp, Lindgren, and Spurr, for example, until we accept the notion that the vein-forming waters ascending from below come not, even in a round-about way, from the surface but that they are a phase of magmatic differentiation. It is the old query, in another phase, whether the sea makes the volcano or volcanoes made the ocean. However that may be, we arrive at this conception, namely, that the ascending mineralizing solutions arrive within a zone, say, a mile thick, where they encounter conditions forcing precipitation and the formation of mineral aggregates constituting orebodies. Here we venture to suggest that the one great factor modifying and shaping the reactions that end in the formation of ore is the existence of a big layer, a zone (irregular in detail, but a thin sheet as compared to the size of the earth) of comparatively stagnant water, containing the oxygen, carbonic acid, and other chemicals derived at the surface, from whence it came. When the up-welling magmatic waters penetrate into the water zone we have a change—of temperature, pressure, and dilution—sufficient to explain many of the results observed within the range of human observation, which happens to reach about as far as the bottom of the water zone. We hope to see this phase of the subject discussed, especially by mining engineers and by the geologists in touch with mining operations, for to them we look for the data likely to advance the study of ore deposits.

NON-TECHNICAL PAPERS publish a good deal of drivel on technical subjects. Here is the *Success Magazine* with a tissue of absurdities concerning gold mining on the Rand. According to this blind leader of the blind, the "gold-bearing reef is forty miles in length, twenty miles in width," and "borings to a depth of 3,500 feet show gold in undiminished quantities." Again, "the rock can be worked for centuries without making a serious impression on its vast extent." We hope the *Success Magazine* will make no serious impression. As to the statements concerning the length and width of the "gold-bearing reef," we are reminded of Euclid's definition of a straight line, that it has length without breadth, and *lies* evenly between its extreme points. Then follows some balderdash about dredging for gold in California, in the course of which we are told that "the dredgers are grinding farms, orchards, and meadows into gold." These "gold-making" dredges are compared with the coolies who are working "the hundreds of cubic miles of gold ore in South Africa." Finally, we are informed that "Science, Invention, and the Machine have conspired to destroy the gold standard." Go to, young man. Take a cold bath, and abstain from alcoholic stimulants; take regular exercise, and avoid newspapers.

Personal.

O. B. PERRY is at Dawson.
 L. S. AUSTIN is at Salt Lake City.
 H. FOSTER BAIN is at Garland, Wyoming.
 CHARLES B. LEWIS, of Nacozari, is at Los Angeles.
 CHARLES BUTTERS is at Victoria, British Columbia.
 J. F. HALLORAN has returned from a tour in Europe.
 PERCY KENYON is on his way from London to Mexico.
 CLAUDE T. RICE has returned to Butte from New York.
 A. C. LUCK has gone from San Francisco to the City of Mexico.

HAROLD WILSON is at Eureka, in San Juan county, Colorado.

GEORGE W. MAYNARD has been examining placer mines in Oregon.

JOHN B. FARISH was in San Francisco this week, on his way to Mexico.

C. F. HUMPHREY is visiting the Empire mine at Downieville, California.

GEORGE W. MYERS has returned from his annual trip to Alaska and Idaho.

ERNST HARMS is superintendent of the Torreon smelter, in Coahuila, Mexico.

J. M. PANNELL is superintendent of the San Salvador mine, at Parral, in Chihuahua.

A. MCKENZIE, of the La Reina de Plata mines, Chihuahua, is on a visit to England.

E. H. GREGORY is manager of the San Carlos mines at Mezquital del Oro, in Zacatecas, Mexico.

F. LYNWOOD GARRISON has returned to Philadelphia from another journey to Santo Domingo.

C. F. PARKER and C. J. CARROL have opened an office as mining engineers at Parral, Chihuahua.

H. P. GORDON, mill superintendent at the Ceresus mine, nearly Hailey, Idaho, is at his home in Oakland.

F. M. PERKINS is now metallurgist for the Williams & Hammer smelter at Magdalena, in Oaxaca, Mexico.

S. H. BROCKUNIER has been appointed manager for the Green Mountain Mining Co., at Silverton, Colorado.

WILLIAM DEMPSTER, of J. S. MacArthur & Co., Glasgow, has reached the Fresno Copper Co.'s mine in California.

A. E. SMITH, lately on the East Rand, is mechanical engineer for the El Oro Mining & Railway Co. at El Oro, Mexico.

W. J. FARAGUT, assistant manager of the Dolores mine, is recovering from rheumatism at the Santa Rosalia Hot Springs, Chihuahua.

W. J. CHALMERS has taken permanent quarters in the Commercial National Bank Bldg., corner of Clark and Adams St., Chicago.

ERNST FAHRIG, of Philadelphia, and his pack train passed Beaver Dam, 40 miles out of Valdez, for the interior on July 25. Dr. Fahrig is assisted by Frank H. Fahrig (his son), E. J. Sachs, and C. E. Hill; they are examining copper and gold property for English capitalists.

Obituary.

WILLIAM HENRY RICKARD died at Redruth, Cornwall, on July 17, 1907, at the age of 71 years. He was the second son of Captain James Rickard and younger brother of Thomas Rickard, now living at London. For more than thirty years he was manager of the mines and smelter at Pontgibaud, in the Puy de Dome, France. When operations ceased at Pontgibaud about ten years ago, he retired, living first in London and then in Cornwall, the home of his forefathers. A capable mine manager, a skilled metallurgist, a truly Christian man, and a good citizen in both of the countries in which he spent his life, he leaves an honorable memory and a fine example.

General Mining News.

ALASKA.

Some good-looking quartz has been brought to Fairbanks from the Innoko by J. T. Smeaton. The ore came from the Mike Rockley claim on Tom Gaines creek. The placer claims on the same creek are producing well. Supplies and men continue to pour into the district, and about 2,000 men are already on the ground.—A rush is on from Haines to the Chilkat district, where an Indian struck some rich quartz.—The first payment on the option on the Sheep Creek properties has been made by W. J. Sutherland, representing the Northwest Mining Syndicate. A crew of men, under G. P. Blair, will soon start work on the properties.

At Juneau, the Alaska-Perseverance M. Co. is dropping 50 stamps and will shortly install an additional 50, for which new equipment is on the ground. Considerable activity in and around Silver Bow basin is being manifested, and numerous new projects are being planned.—At Treadwell the recent installation of oil tanks along the Gastineau channel on the works of the Alaska-Treadwell G. M. Co. are the most striking objects that arrest the visitor's attention on approaching Douglas island. It is expected that all the stamp-mills will be operated by fuel oil in a short time, and each mill will have its own separate plant.—At Nevada Creek, the Alaska Treasure M. Co., operating near Juneau, expects to start up its new 20-stamp mill some time this fall on good ore. This mine is on Douglas island south of the Treadwell properties. F. M. Stone is the manager and M. S. Hudson the superintendent.—The smelter at Hadley has been closed down, due to lack of fuel, but has resumed operations again.

ALABAMA.

TALLAPOOSA COUNTY.

The Silver Hill mine has been cleaned out and examined by Birmingham capitalists. This is an old property that is reported to have produced rich ore.

ARIZONA.

COCHISE COUNTY.

The feature of the last week in mining circles at Bisbee has been the strike of ore on the 1,100-ft. level of the Denn-Arizona property. This ore was struck a few months ago on the 1,000-ft. level and a drift on this level was in ore for 55 ft.—The Copper Queen Co. is considering the advisability of using small electrically driven pumps to handle the normal flow of water, retaining the heavy ones at present in use for the increased flow during the rainy season. Also, there is a new plan under advisement for a centralized haulage and hoisting scheme, with all the working drifts converging toward the Sacramento shaft, which will be the central point of the new system.—At the Czar shaft of the Copper Queen the work of widening the pump-column compartments is finished, with the exception of a little work on the stations, and the new wood-lined pump is working satisfactorily at the Holbrook. At the Cuprite shaft drifts are being run in various directions, but no strike of importance has been made. Work at the Calumet & Arizona smelter at Douglas is progressing, the new power-house steel frame is complete, the new blower and engine and 500-kw. electric unit new condenser and circulating pumps have been placed on their foundations. The ore shipments from the mine exceed the capacity of the four furnaces in operation, and the stock-pile at the smelter is growing.—The relay-pump station on the 1,200-ft. level of the Junction shaft of the Superior & Pittsburg has been timbered, and will soon be ready for the pumps. Stoping continues on the 900 level, and the orebody found on the 1,100 level will be developed as soon as the pumps are working. Drifts have been started north, east, and south from the Hootson shaft, and stoping has been started on the 1,100-ft. level. Shipments from the Cole shaft are increasing.—The new compressor of the Shattuck-Arizona will be in operation this month. Toward the end of July this company was producing 400 tons per day, 200 tons of sulphide ore going to Globe, and

200 tons of oxide ore to the Copper Queen smelter. The east extension of the drift on the 900-ft. level is still in ore running about 4%, and the south extension has been driven about 175 ft.—During the last month the Bisbee Extension Co., operating six miles west of the city, sunk its shaft 63 ft. in 25 working days, with two shifts. The shaft is down 375 ft. and is entering a broken limestone zone that looks favorable for ore. Prospecting on the surface along the fault 100 ft. north of the shaft shows some copper stain. An air-compressor will be installed this month.—The attempts to unionize the smeltermen at Douglas continue, but little progress is being made by the agitators.

Some good results are reported from development work on the ground of the North Bisbee Development Co., four miles north of Bisbee. Porphyry, granite, limestone, and schist all occur in that region. This company has sunk a shaft 70 ft., and has cross-cut for 15 ft. A vein has been discovered that carries copper carbonates. H. S. Jones is president and E. H. Clark superintendent.—The Copper Queen company is working on its plan for a new hoisting plant at the Sacramento shaft, out of which will be hoisted all the ore from every shaft belonging to them. To this end the large Nordberg hoist which will be used has been ordered and is being built. The system to be employed in this work is elaborate. After the drifts from the various shafts have been completed the transportation problem will be solved by a complete trolley system, for which the power-plant will furnish the current. This will be installed in a few months. The hoist will have a capacity of from 3,500 to 4,000 tons per day, although no such output as this is contemplated by the company at present.—For the purpose of making the final payment on the Minneapolis Mining Co.'s property, bonded about a year ago to Minneapolis people headed by J. W. Christy, C. I. McReynolds arrived in Douglas recently. The original owners of the property were Nihart & Wall, of Douglas. The Minneapolis group is situated near Campas and has been developed extensively since the property came into the hands of the present owners. Ore has been opened up and regular shipments are being made to the smelters. At the new C. Q. power-plant the first equipment will not be large, but both building and equipment will be enlarged to meet the demands of the mines. The initial machinery equipment will consist of three turbo-generators and three air-compressors. An oil storage tank with a capacity of 200,000 gal. near the same place is now nearing completion and will be ready for use shortly.—A good strike is reported to have been made at the Hershall mine at Tombstone. A vein 10 to 18 in. wide was struck 35 ft. below the 350-ft. level, which shows horn silver and gold.—During the past few weeks new strikes have been made in the Dragoon Mtn., about 20 miles east of Benson; in the Rincon Mtn., north of Benson, on two different properties; on the Catalina Mtn., just north of the Rincon Mtn. and in the Whetstone Mtn. about 20 miles southwest of Benson. During this time several new camps have been established.

SANTA CRUZ COUNTY.

(Special Correspondence).—C. A. Overlook, manager for the Arizona M. & T. Co., reports good results in the Los Angeles mine at Douglas. The smelter returns on the last car of ore shipped gave 12.5% copper and 46 oz. silver. Four cars of this high-grade ore was taken from the shaft, which is now only 60 ft. deep. At the bottom a drift was driven from the shaft for 12 ft. and is all in ore. Forty pack animals are carrying ore to Nacoari, eight miles away, and from 30 to 35 men are at work in and about the mine. A good wagon-road can be built to the mine from the Southern Pacific, now being graded, a distance of nine miles, but until this is done the ore will be packed to Nacoari for reduction.—It is the intention of the Two Queens company, owning gold and copper mines at Winkelman, to push development operations. Machinery has been ordered from Los Angeles, including a 25-hp. gasoline hoist, cable, ore buckets, etc. The roadway to the mines from the railroad will be in readiness for hauling the machinery upon its arrival. As to recent progress, shaft No. 1 is down 217 ft., or 60 ft. below the tunnel level, and shaft No. 4 has reached a depth of 155 ft., with a cross-cut

of 26 ft. toward the vein. This cross-cut may cut the vein at any time now.

Prescott, August 5.

YAVAPAI COUNTY.

Thomas W. Lawson of Boston now owns the Humboldt smelter near Prescott, having secured on July 9 all but 25,000 shares of the capital stock of the Consolidated Arizona Smelting Co.—David S. Rose of Milwaukee has taken over, under bond, the McDermott group of mines, in the Big Bug district. The deal is the result of a visit to the property about a month ago.

CALIFORNIA.

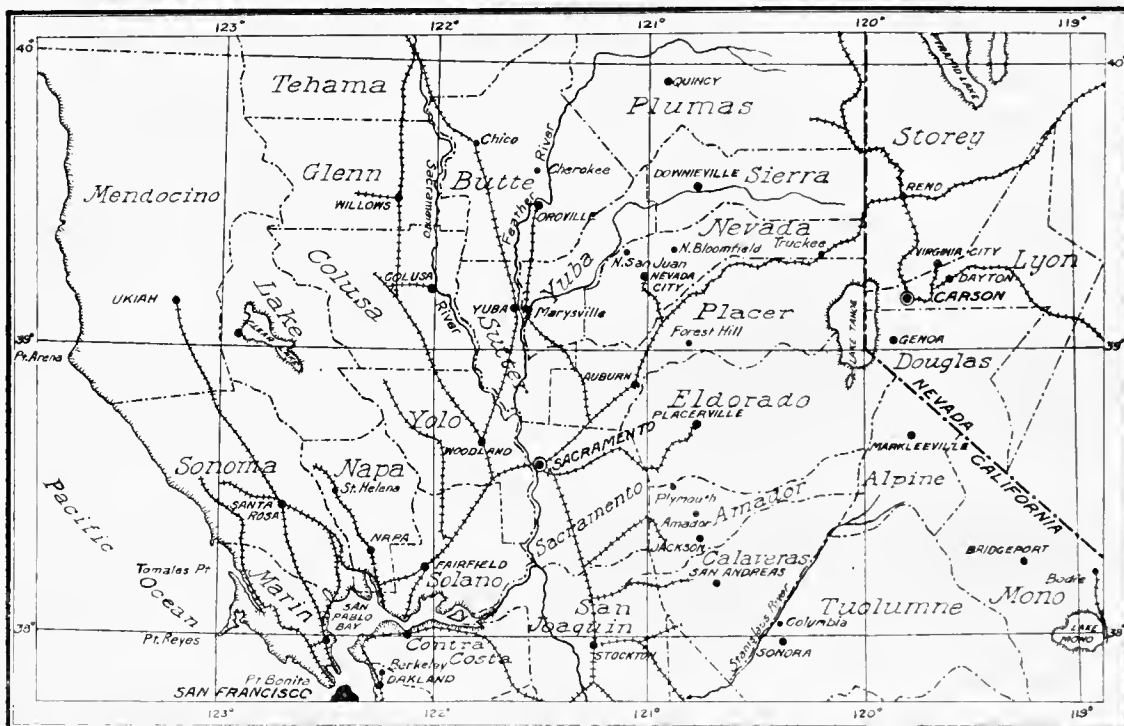

CALAVERAS COUNTY.

Conflicting reports emanate from Angels Camp, where the strike has been on for several months. It is stated that the mine-owners have offered to allow the men to return to work on a nine-hour basis, and that if they do not accept, the camp will be run on the open-shop principle. Another rumor has it that the Stanislaus Electric Power Co. has

The new mill, including ten stamps, and Wilfley concentrators, is in place, and will be running within two months. The battery foundations were built for 20 stamps, and 10 more will soon be erected. Excavating for the flume and power-house has begun and about 600 hp. can be generated. A gravity tramway 400 ft. long will be built from the tunnel to the mill. The main tunnel is in 500 ft. and 2,000 ft. of driving has been done.

NEVADA COUNTY.

A big electrical pump is being made at Taylor's foundry for the Sultana mine; it will be placed on the 800 level, and will have a capacity of 500 gal. per min. on a 2,100-ft. incline. The pump is driven by chains from the motors.—A 250-hp. Norwalk compressor is being installed at the Empire. It was formerly at the Allison ranch, and can be driven by steam or electricity, and may be used to operate the mine pumps in cases of emergency.—The work of unwatering the Kenosha is proceeding satisfactorily, and the foundations for the new Cornish pumps are completed. One pump will be placed at the 300 and one at the 500-ft.

Map of Central California.

entered into negotiations with the Utica Mining Co. for the purchase of the mining company's water-rights, flumes, ditches, pipe-lines, and power-plants. If this deal goes through, it will mean the permanent abandonment of the Utica property. The stockholders of the Lightner Mining Co. voted recently to close down that mine, and it looks as though Angels would be permanently put out of business.

EL DORADO COUNTY.

Some good indications have been encountered in the Crane Gulch mine, and this old-time producer may be again productive.—A survey of the Woodside-Eureka mine has just been completed.—A compressor will be installed at the Alpine mine, and hand work done away with.—The first level of the Taylor mine will soon be free of water and the pumps are running to their full capacity. The Thompson brothers are operating the property.—Seventy men are employed at the Eureka slate quarry and a large amount of finished roofing slate is being turned out every day.—The overburden will be hydraulicked from the veins outcropping on the Arterburn & Shultz group. A survey has been made and a pipe-line will be laid.—The main tunnel at the Cooley mine is being driven ahead to get under the centre of the channel.—Sinking continues on the Blue Rock mine, but pumps will have to be installed, as some water has been encountered.

INYO COUNTY.

Fifty men are employed at the Casa Diablo property.

levels.—Work has been resumed at the Union Hill mine, on the line of the Nevada county narrow gauge railroad, two miles from Grass Valley. The property has been idle for 15 months, but now the pumps are working and the mill has been running for a week. L. P. Doe of San Mateo is financing the work.—At the Banner mine the 700-ft. station has been reached in unwatering the shaft, and the Knowles station pump at that point has been started to help the sinkers.—The Murchie, Charonnat Union, and Murchie Extension properties in the same belt with the Empire, are attracting attention.—J. S. Goodwin and associates will erect a hoist on the blue lead gravel mine near You Bet, preparatory to building a well to work on the cement gravel.

SHASTA COUNTY.

A diamond-drill outfit is being hauled to the Sugar Loaf mine from Coply. This property is being developed by Fillins, Grotefiend & King, who employ about 40 men.—The Shasta-Kennett Copper Co., of which Martin Lindley is president, is operating in a small way one-half mile northeast of Kennett. A tunnel has been run 600 ft. during the past year.—The diamond-drill for the Vulean Copper M. Co. has arrived at Kennett and will be shipped to the mine at once. The drill was made by the Sullivan people and has a capacity of 1,000 ft., with a core about one inch in diameter. Dan Longton will operate the machine.—The Heroult iron smelter is now in regular operation, after a delay

caused by charging the voltage of the apparatus.—Development work at the Summit mine is being rapidly pushed. Tunnel No. 3 is in 400 ft., following a contact of rhyolite flows and the gouge carries a little gold and copper. Tunnel No. 2 is in 300 ft. and a raise has been run 50 ft. A small air-compressor is driven by a 50-hp. Westinghouse motor.—A strike is reported in the Ten Lakes mine, west of Edgewood, which is being developed by the Osborne brothers.

SISKIYOU COUNTY.

The Humboldt-Siskiyou company has been organized to work a quartz vein three miles from Callahans. H. Hersey is the superintendent. J. K. Firth, of the Allis-Chalmers company, has got the contract for a 10-stamp mill.—A new dredge is to be built on the south fork of Scott river at Callahans, having been contracted for by the Risdon Iron Works.—A new electric pump has been installed at the Sheba mine on Patterson creek, in Scott valley.—J. H. Morrison, of Quartz valley, has sunk an incline shaft on the Luke Shaw vein for 100 ft. Some good milling ore is being developed in F. H. Osgood's mine on Taylor creek.—The Holman-Foskett company is employing 20 men at their mine in White's gulch, near Snowden.

IDAHO.

SHOSHONE COUNTY.

The Bunker Hill & Sullivan Co. is shipping between 8,000 and 9,000 tons of ore daily, and is working a force of 500 men in the mine. The entire body in which they are working is of high grade, assaying 55% lead and about 19 oz. silver, and about 10 cars of ore per day have been shipped. The company has been forced to dump ore for a time in the yards because of not having cars enough to load, as it is usually supplied with about 50% of the cars required. At one time last season there was \$200,000 worth of concentrate heaped in the yards waiting to be loaded for shipment to the smelter.—The last dividend of \$180,000 was paid August 4; dividends have been paid at the rate of \$1,340,000 a year, and are soon to be increased because of the enlarged and improved milling facilities.—The C. E. Mitchell Co. of Spokane, operating the East Snowstorm extension at Mullan, has ordered machinery for sinking a double-compartment shaft. The decision to sink the shaft was reached after a conference between officials of the company and John M. Serafford, manager of the property. Power will be supplied by the Washington Water Power Co. of Spokane, which recently completed its line to within a short distance of the property. The company expects to be shipping ore before they have reached the bottom of this 200-ft. shaft, as they have been working along the hanging wall and have cross-cut 112 ft. without striking the foot-wall, and a 20-ft. prospecting shaft showed shipping ore. Twelve inches of bornite ore, carrying native silver, is the latest strike reported from the Snowstorm mine at Mullan. The strike was made in the lowest level in the property. The drift for more than 100 ft. had been in copper ore, the vein being wide. The Snowstorm ore has always carried silver, but not in commercial value. The extent of the vein has not yet been ascertained.—The Little Pittsburg on Pine creek in the Coeur d'Alene is coming to the front since it was taken under bond by S. P. Williamson. A cross-cut has been started from a point near the face of the main tunnel, designed to cut the main vein, which is stripped on the surface. It is believed this cross-cut will have to be run a distance of 1,100 ft. to cut the lode. The depth of the ore-shoot will be 250 ft. The vein on the surface is 11 ft. wide, and has been stripped nearly the entire length of the claim. Indications of a large orebody are evident at 1,100 ft. The main tunnel is now in 350 ft. A cross-cut was run 240 ft. from the mouth of the tunnel. This shoot was two and one-half feet wide. Assays from it returned as high as 70% lead, 22 oz. silver, and 12% zinc.—The entire Coeur d'Alene country is looking better than it has for years. The 200-ton mill that is being installed at the Stewart will be completed soon and ready to begin milling. The mine is shipping 15 carloads per week of commercial ore, which is marketable without being milled, working a shift of 15 men. Everything is in first-class condition.—At the Oom Paul a shaft

has been sunk 500 ft., and they are driving from each side of the shaft and expect to strike the ore-shoot in a short time.—Articles of incorporation of the Clearwater Gold & Copper Mining Co., have been filed in Wallace, which is designated as the principal place of business and the company is capitalized at \$2,500,000, divided into 500,000 \$5 shares. The incorporators and directors for the first year are Michael Steffans and John H. Wourns of Wallace, and Samuel Seidenfield of Spokane. The entire capital stock of the company has been subscribed by the incorporators. The company was formed to develop the Morning Star, Morning Star Fraction, Evening Star, North Star, and Golden Dollar lode claims, and the Old Crow, New Idea, and Q. S. placer claims, all situated on the north fork of the Clearwater river 18 miles from the Amador mine, in Shoshone county.—Mayo Sachs & Co. of Butte, have made the final payment of \$25,215 on the purchase of the controlling interest in the Alameda mine. The drift is now 42 ft. inside of Alameda ground, and they expect to complete the 100-ft. contract by August 15 and will then start cross-cutting north and south for the contact veins which are known to exist from the work in the Alameda tunnel 300 ft. above the present workings. There is no ore in the face of the tunnel, the orebody being to the south, but they expect to reach it by cross-cutting.

NEVADA.

CHURCHILL COUNTY.

(Special Correspondence).—The shaft on the Belle-Hellen is down 75 ft. and cross-cutting from the bottom of the shaft is under way. Some good ore is in sight.—The Daisy Wonder shaft is down 160 ft. in good ore. The shaft is equipped with a 25-hp. gasoline hoist.—A 6-ft. vein has been encountered in Tunnel No. 5 on the Nevada Hills. A hoist has been installed. 1,000 sacks of ore are at the mine and the chutes are full.—A vein has been struck in the bottom of the Fairview Eagle shaft at a depth of 218 ft. A flow of water was also struck, which compelled the bulk-heading of the drift and suspension of operations until a pump can be installed.—The Spider-Wasp Extension shaft is down 50 ft. and will be sunk to the vein.—The tunnel in the Vulture is in 650 ft. and some fair ore has been found.—The shaft at the Imperial Wonder is down 70 ft. A 15-hp. hoist is being installed.—A shoot of ore was recently found in the lower levels of the Jackpot, and development work is under way.—At the National Wonder, the shaft is down 65 ft. in ore. This mine adjoins the Jackpot and is controlled by the same company.

Fairview, Aug. 6.

ESMERALDA COUNTY.

During the week ending August 10, the ore from the mines at Goldfield was disposed of as follows: Shipped to smelters, 575 tons; shipped to mill, 2,584; and treated at Combination mill, 450. Total output, 3,709 tons, of an estimated gross value of \$400,000. This output and value are below those of the previous week, when the Mohawk and Combination mines made extra shipments of high-grade ore. Small shipments were made for the first time from Mohawk Ledge and Rogers Goldfield Syndicate properties.—During this week the Nevada Goldfield Reduction Works received consignments of ore as follows: Mohawk Florence, 390 tons; Mohawk Jumbo, 326; Mohawk Combination, 693; Red Top, 270; Mohawk, 453; Little Florence, 34; Frances Mohawk, 91; Higginson lease, 95; May Queen, 9; McNaughton lease, 68; Rogers Goldfield Syndicate, 25; Hayes-Monnette dump, 130.—A new lease on the Miss Jessie claim of the Red Top company has been given to J. H. McMillan and George B. Hofferan. A three-compartment shaft is down 185 ft., a head-frame is being built, and the 75-hp. gasoline hoist from the Frances Mohawk No. 1 lease will be used.—A diamond-drill will be placed in the bottom of shaft No. 7 on the White Rock claim of the Begoles Mines Syndicate, to prospect the ground in every direction.—An extension of the lease on the Deserted claim of the Silver Pick has been granted to the Goldfield Silver Pick L. Co. A shaft has been sunk 300 ft. and 700 ft. of driving has been done.—Reports state that the Etawanda company, operating five miles east of

Goldfield, has struck ore on the 115-ft. level.—The Congo tunnel on the Nevada Queen property is in 345 ft. and a raise has been started for the surface for ventilation. Donald Ferguson is the manager of the property. On the Pittsburgh Nevada the shaft is down 120 ft.—The shaft of the Diamondfield Red Mtn. Co. has passed the 100-ft. point.—There is good ore exposed in the winze on the 420-ft. level of the Kewanas, and some copper is coming in with depth.—It is possible that the Goldfield Consolidated, regarding the overcapitalization of which much has been written by mining men, will pay a small dividend in September.—The Mohawk Combination L. Co. will soon pay its first dividend of 10%. The company is shipping about three carloads per day, and the lease expires in about four months. Fred Siebert is in charge of the work.—An English syndicate has taken a lease on the Grandma ground and has started diamond-drilling. A steel head-frame and 100-hp. hoist will be erected and sinking started.

HUMBOLDT COUNTY.

(Special Correspondence).—Since the reopening of the Glasgow and Western Exploration Co.'s reduction works, this town is enjoying some of its oldtime prosperity. The Gold Run district is coming to the front. The principal properties are the Adelaide, Georgianic, Florence, Gold Reef, and Great Republic.—The shaft on the Adelaide is down 300 ft. and 70 tons of ore are treated daily at the reduction works.—A 50-ft. shaft and numerous prospect holes have disclosed some ore in the Georgianic.—On the Florence several small shafts have been sunk, and open-cuts have exposed the vein.—On the Gold Reef, four shallow shafts have exposed small veins carrying gold and silver.—The Great Republic has a good record as a producer, and the main vein is stripped for 2,000 ft. The ore is lead-silver.

Goleonda, Aug. 7.

LYON COUNTY.

The Nevada Mammoth G. M. Co. owns 26 claims in the old Cambridge district, 28 miles south of Yerington. Eastern investors have recently bought a large block of the stock and a valuable water-right on the east Walker river will be purchased.—A carload of copper ore has been shipped from the mine of the Union Blue company.—The shaft of the Wabaska Copper Co. is down 100 ft. and a cross-cut will be driven to the vein.—From Ramsey comes the report of a strike in the Walkover mine.

The Ramsey-Comstock mine has commenced shipping ore to the Utah smelters. The hanging wall ore-shoot has been driven on at the second and third levels for a distance of 150 ft., and the ore extracted has been sacked for shipment. They have started a stope from the second to the third level, and continue driving. Near the east end-line of the Ramsey-Comstock ground, the Ramsey-Ophir Mining Co. is developing the same vein. A raise of 60 ft. from the tunnel level is well started and sinking will commence as soon as it is finished. They have found some ore in the vein and will sink as deep as the adjoining mine, on the hanging wall, where the rich shoot occurs.—The Walkover Mining Co. has commenced sinking on its ground west of the Comstock. They have a hoist and will develop the vein that was exposed with a tunnel 25 ft. from the surface. Some ore is piled on the dump. The Ramsey-Bonanza company will soon install a gasoline hoist, gallows frame, etc. They are to continue sinking the two-compartment shaft to develop the vein.—The Ramsey Consolidated Co. will sink on their four-foot vein on Dago No. 1 claim. The cross-cut from the 300-ft. level on Dago No. 2 claim is in 18 ft.—The Ramsey-Goldfield M. & R. Co. will sink on the hanging wall of their vein, the west extension of the Ramsey-Comstock. A vein has been exposed and a hoist will be erected.—Several thousand feet of workings are opened up at the old Garavanta mine, and the owners are steadily increasing the extent. They are getting ready for a mill and improved machinery.—George Wingfield, H. T. Bragdon, and several other Goldfield men are making ready to develop the Red Mountain dike, southwest of the Ramsey-Comstock.

NYE COUNTY.

(Special Correspondence).—A vein has been found in the 1,250 level in the North Star. Ore has also been struck in the 950 and 1,050-ft. levels.—Ore is being developed in the 800 level in the Midway, and a raise is under way from the fourth to the third level.—Some good ore has been found in the Jim Butler, in the lower levels.—The shaft of the Mizpah Extension has been repaired and re-timbered to the 600-ft. level, and a 50-hp. hoist installed. Ore is being developed on the 500 level.—The Tonopah Extension is developing an orebody on the 1,050 level. It is reported that the ore will be treated at the Montgomery-Shoshone plant at Bullfrog.—The hoists and fittings of the Ohio shaft on the West End are being transferred to the new shaft, which is being sunk to connect with the lower workings. Good ore is being exposed.—It is announced that the Tonopah Standard will be re-opened and the shaft put down to the 1,000 level.—Small shoots of promising ore have been struck in the Tonopah Buckeye. The shaft is down 125 ft.—A large force of men are engaged in developing the lower levels of the Tonopah, and much virgin territory has been opened up. The mine was recently inspected by J. W. Brock.—At the Mizpah good ore is being extracted, and driving is under way.—The Union district is attracting attention by reason of strikes made in the Berlin, North Butte, and others. Ore running well is said to have been found on the Richmond claim of the Berlin. The lease is operated by Kendall & Douglass, who are employing a large force of men.—Several placers are being operated in the Walker Reservation, and some nuggets have been found.

Tonopah, Aug. 9.

The 40-stamp mill of the Montana Tonopah is complete, and will commence dropping its stamps this month. It will run at half capacity at first, due to the lack of power. To remedy this it will be necessary to divert all the power from the mine to the mill, running the hoist and compressor with steam. The Hendryx system of agitation will be used in the cyaniding department. A. P. Carter will be in charge of the mill. It is claimed that \$8 ore can be treated at a profit.

NEW MEXICO.

The mining business in the Mogollon district is in better shape than it has been for many years. The Last Chance mine alone gives employment to about 90 men. The 80-ton cyaniding and concentrating mill is running full time and bullion and concentrate are shipped to Silver City. This mine, which is operated by the Ernestine Mining Co., is reported to have produced more silver last year than all the other mines of New Mexico combined. E. Craig is at the head of affairs. The mill, running on sulphide and chloride ores, saves 95% of the precious metals. J. T. Griswold is mine superintendent, and A. M. Redfern, mill superintendent. The workings extend 500 ft. below the tunnel level.—At the Deadwood mine two shafts are down 100 ft. and 240 ft., and driving and cross-cutting are going on in the lower levels; 20 men are employed.—To the west of the Last Chance is the Tip Top mine, owned by D. R. Brownell and John Coffey, on which development work is proceeding.—The Little Fannie property is closed down at present, but work is expected to start soon. The shaft is down 550 ft. and a good hoist is in place, with a capacity of 1,000 ft. This mine is worked by the Mogollon Mtn. Investment Co., promoted by W. J. Weatherby and T. J. Cooney.

OREGON.

BAKER COUNTY.

The United Elkhorn mine is a promising property, and much progress has been made the past year in the way of development, but they have been unable to do any milling for a few months past on account of the volume of water in the lower levels. This is now being overcome, and the usual production is confidently looked for.—At Sumpter, the North Pole mine of the Eastern Oregon M. Co. and the Columbia mines are working steadily with satisfactory results. All the other properties in the district are idle.—At Geiser, one of the most promising properties is the

Phoenix mine, under the management of Chas. F. Parker. The 10-stamp mill is steadily pounding on good ore, and much new development is under way. The mill at the Bonanza mine has not been running for several weeks, and it is rumored that Eastern parties have been interested, with ample capital to take over the property.

TENNESSEE.

CLAIBORNE COUNTY.

(Special Correspondence).—At the mines of the Tennessee Zinc Co. a 50-ton concentrating mill is running, with an equipment of jigs and tables. A disintegrating screen has been installed to handle high-grade carbonate ore, and a flotation plant is being erected. The mine is opened by a 700-ft. tunnel, and work is carried on both above and below this level. An underground stream was found in the lower workings.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The cross-cut from the No. 2 adit of the Copper Key mine has intersected 53 ft. of ore, but the hanging wall is not yet in sight.—A contract has been let to drive 300 ft. of an adit by the Bortle Copper-

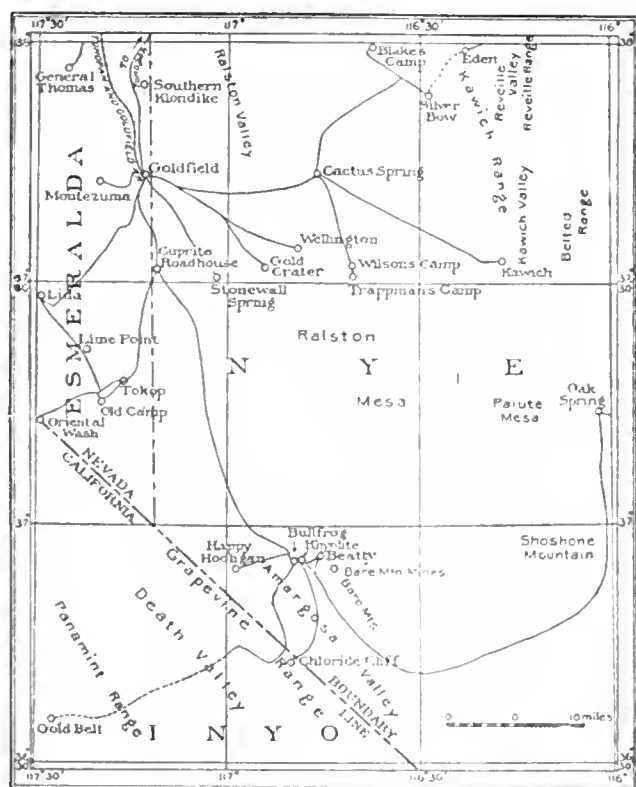

on the Regina vein; the last 15 ft. is on copper-bearing quartz, three to four feet wide.—A contract has been let to drive 50 ft. of an adit and to sink a shaft 200 ft. on the Summit mine.—Rich gray copper ore has been struck at a depth of 20 ft. on the Copper Queen mine, near Chewelah. Republic, Aug. 12.

BRITISH COLUMBIA.

The coke shortage, curtailing the capacity of the smelters, has resulted in a decreased output from the Rossland district for the week ending August 3. The coke companies at Crow's Nest Pass claim that since the strike they have been unable to get men enough. The Northport smelter was forced to close one of its furnaces, and there is hardly enough fuel to keep the other two running. At the Granby smelter at Grand Forks three furnaces have been shut down and the fuel supply is rapidly running short. The Trail smelter is running with a small fuel reserve.—During the week the Centre Star shipped 2,440 tons; Le Roi, 2,205; Le Roi No. 2, 245; White Bear, 70 tons. Total, 4,960 tons of ore, making a total production for the year to date of 163,232 tons. The last of the War Eagle electric motor has been shipped to the Snowshoe mine at Phoenix, and the machine will be installed at once. At the Le Roi the drift on the 1,350-ft. level toward the winze workings is in 120 ft. The mine could increase its production materially if the Trail smelter could handle the ore.—The vein on the 700-ft. level of Le Roi No. 2 is showing up well with development.

At the Consolidated smelter at Trail, there were received during the week 4,449 tons of ore. Besides the Rossland shipments, other consignments were furnished as follows: Snowshoe, Phoenix, 916 tons; Victoria, Nelson, 73; St. Eugene, Moyie, 757; La Plata, Kokanee creek, 30; Lone Bachelor, 15; Lorna Boone, Silverton, 1; Vancouver, 20; Jo-Jo, Three Forks, 8; No. 1, Ainsworth, 21 tons of ore.—The Northport smelter received 2,205 tons of ore.—The shipments from southeastern British Columbia for the week were as follows: Boundary, 30,567 tons; Rossland, 4,140; East of the Columbia river, 3,025 tons. Total, 37,732 tons; for the year to date, 943,978 tons of ore. The shipments were divided among the various smelters as follows: Grand Forks, 13,709 tons; Greenwood, 10,130; Boundary Falls, 5,832; Trail, 4,449; Nelson, 253; Northport, Washington, 1,793; Marysville, 600 tons. Total, 36,766, and for the year to date 883,636 tons.—Boundary ore shipments fell off about 7,000 tons this week on account of ear shortage and freight congestion. The Granby smelter received from Granby mines 13,649 tons; from Emma, 60. The British Columbia Copper Co.'s smelter from Mother Lode, 7,040; from Snowshoe, 2,970; from Emma, 60; Mountain Rose, 60 tons. The Dominion Copper Co.'s smelter from Brooklyn, 1,664 tons; from Rawhide, 2,272; Idaho, 320; Sunset, 1,516; Mountain Rose, 60 tons. Trail smelter, from Snowshoe, 990 tons. Total shipments for week, 30,671 tons.—Boundary smelters during the week treated are as follows: Granby, 13,115 tons; B. C. Copper Co.'s smelter, 11,160; Dominion Copper Co.'s smelter, 5,842. Total for week, 30,117 tons of ore.

Diamond drilling has been resumed on the Monarch claim of the Granby company by Boyles Bros.—At the Gold Drop, an intermediate tunnel between the Curlew tunnel and the main workings is being driven by contract. This will connect with a raise from the lower tunnel.—A new syndicate has taken over the Riverside mine, near Rock creek. W. E. George is in charge of operations.—The Canadian Pacific railway reports that 100 steel dump-cars have left Montreal to be used in the ore traffic of the Boundary district.—It is planned to build two converter stands at the smelter of the Dominion Copper Co. At present the matte from Boundary Falls is being blown to blister copper at the converting plant of the B. C. Copper Co. About 100 men are employed at the Dominion Copper Co.'s Rawhide mine, and a large amount of ore has been developed.—There are more men on the payroll of the St. Eugene at Moyie, in East Kootenay, than ever before. The Lake Shore shaft is to be sunk another 100 ft., making 600 ft. in all.

Part of Nevada.

Gold Co.—The Copperopolis Mining Co. is constructing two miles of wagon-road from the Last Chance, a copper-gold mine, to a point near Kellar.

Republic, Aug. 12.

OKANOGAN COUNTY.

(Special Correspondence).—John Boyd, manager for the Palmer Mountain T. & P. Co., has arrived at the mine from New York, where he has secured capital for the work in hand.—The Allen Gold M. Co. has received and is installing hydraulic machinery at the Mary Ann creek placers, near Chesaw.—The Oroville Consolidated Mines, a company operating near Oroville, has struck a body of copper ore in a shaft recently started.—Horace F. Evans, of England, is making a geological examination of the mineral districts in the northern part of Okanogan county, presumably in the interest of an English syndicate.—Ore is being shipped from the O. K. mine, on Kruger Mtn.—The Kruger Mountain M. Co. has struck a large body of good ore near Nighthawk.

Republic, Aug. 13.

STEVENS COUNTY.

(Special Correspondence).—A shaft has been sunk 65 ft.

Special Correspondence.

Mexico City.

*The Lucky Tiger or El Tigre Litigation.—A Long Battle.—Conflict-
ing Railroads.—National Metal Co.—New Works.*

The long legal battle over the possession of the Lucky Tiger mine (called in Mexico El Tigre Suerte), now made famous by reason of this litigation, is thought to have been finally concluded last week by the unanimous decision of the Supreme Court of Mexico affirming the decision of the Federal district judge of Sonora in granting the *amparo* and suspension against the Enseñada Mining Co. in favor of the El Tigre Mining Co. The Lucky Tiger mine is situated in the Moctezuma district of Sonora, and a little over two years ago was obtained under option by B. F. Graham and associates, who in turn passed the option over to the El Tigre Mining Co. of Kansas City for a certain consideration to be paid Graham and his associates, Graham at the same time becoming president and general manager of the company. Work on the property showed it to be much better than was at first supposed and Graham seems to have conceived the idea of getting it for himself. He therefore resigned from the El Tigre Mining Co. and organized the Enseñada Mining Co., obtaining options from the creditors on the amounts due from the El Tigre company. Then when on July 6, 1905, the El Tigre people deposited \$48,864 in the bank of Bisbee, to be distributed in a certain proportion among the various creditors, Graham claimed the apportionment was not correct, refused to accept the money, and declared the property forfeited for non-payment. The following day, July 7, 1905, Graham proceeded to the property with an armed body of men and took forcible possession. The El Tigre company immediately proceeded against Graham both civilly and criminally, and finally obtained possession on December 13, 1905. Then followed numerous decisions and appeals, with probably some manipulations (as one judge was removed from office by reason of his decision), until now it is hoped the final decision rests in the judgment rendered by the Supreme Court in Mexico City. It seems the main dispute was whether or not the El Tigre Mining Co. had made the payments due, and the Supreme Court has decided that in depositing the amounts due in the banks to the credit of the various persons the company had complied with its part of the contract. The El Tigre company has been in possession of, and working, the mine since December 13, 1905, and has deposited close to \$300,000 in the bank at Bisbee for the stockholders of the Enseñada company, which the latter have refused to accept. It is to be hoped now that the battle is ended and the property may be developed as it deserves to be. It is possible that there is more in the fight than the mere possession of the El Tigre mine, for on February 17, 1906, the fight passed from Graham to Epes Randolph, who succeeded the former in the presidency of the Enseñada company, and many of the El Tigre company are closely associated with A. E. Stilwell in his Kansas City, Mexico & Orient Railroad, which is building across Chihuahua and Sonora to the Pacific coast. Epes Randolph is Harriman's head man in Sonora, and, it would seem, was too wise a man to take up a fight which had no better prospects than that started by the Enseñada Mining Co. And this past week there has arisen the rumor that the Harriman (Southern Pacific) interests are making every effort to beat Stilwell (the Kansas City, Mexico & Orient) to the Pacific coast.

The National Metal Co., which in April, 1905, took hold of the old sampling and testing works of Heckel-

mann & McCann and placed therein a gold and silver electrolytic refinery, has been successfully operating the plant since November, 1905, obtaining bullion as well as cyanide and sulphide precipitates from all parts of the Republic. The concessions from the Mexican Government, to which it sells all its refined gold, enables the company to give especially advantageous prices in the purchase and refining of doré bars. The end of 1906 saw the company producing 500 oz. of fine silver and 25,000 oz. of fine gold, which was about two-thirds of the capacity of the present plant. But the business has continued to grow until the company has been forced to build a new and larger plant. Twenty-five acres of land have been purchased in a most favorable part of Mexico City, near Guadalupe; the plans have been completed, the machinery ordered, and construction will be pushed as rapidly as possible. The new plant will have about three times the capacity of the present and will be a model in every particular. In addition to the electrolytic work, a small blast-furnace is to be built for treating the rich lead slags from the doré furnaces.

William Warr, associated with H. W. Blaisdell, of Los Angeles, in the Blaisdell Coscotitlan Syndicate, has just returned to Los Angeles from their works at Pachuca, Mexico. The company was organized to purchase and treat tailing deposits found near old mills at Pachuca. It is estimated that they have over 2,000,000 tons, averaging \$4 per ton. A complete cyanide treatment plant has been recently built to handle 500 tons per day, and with reasonable luck it is believed it will take 15 years to exhaust the tailing on hand.

Corrigan, McKinney & Co. of Cleveland, Ohio, have purchased the San Rafael copper mine at Terrazas, in Chihuahua, from Dale Bros., of Chihuahua, Felix McDonald, of Terrazas, and W. F. Biernham, of Boston, Mass., the consideration being \$50,000. This company was formerly the owner of the Concheno gold-silver mines, which was sold to W. C. Greene and associates for \$1,250,000. It is stated that the company will install new machinery and develop the property. The work of sinking two shafts will be started at once.—The capacity of the 200-ton copper smelter at the Rio Tinto mines in the Terrazas district is to be increased to 800 tons. These mines and smelter are owned by American interests closely identified with the American Snuff Company.—The Tejana Mining Co., which is composed of Laredo, Texas, men, has leased the Guajardo and La Constancia copper mines, situated in the Concepcion del Oro district, State of Zacatecas. The same company has acquired the Pinitos mine, in the same district.

The Los Angeles & Jalisco Mines Co., which purchased the Magistral copper mines in the Etzatlan district, Jalisco, from W. M. Mathews, is now receiving net returns of \$3,000 monthly from ore shipped to the smelter at San Luis Potosi. M. N. Graves, of Guadalajara, is manager of the company.

There is a big rush of prospectors to the rich copper discovery in Santa Cruz mountains, district of Magdalena, Sonora. The discovery was made by Edwin Arnold, mayor of Cananea, while on a hunting trip. The ore is copper sulphide. The assays run from 40 to 50% copper, with 7 to 11 oz. gold. Many claims have been taken, among them being about 8,500 acres of mineral land that were filed upon by W. C. Greene.

The Jimulco mine, in Coahuila, is producing about 80 tons of rich copper ore daily. The ore is shipped to the smelter at Aguas Calientes. The principal stockholders of the company are O. S. Newell, Otto Koehler, and Otto Wahrmond, all of San Antonio.—The Greene Gold-Silver Co. is preparing to start up its El Salto mill at Ocampo. It will also install a cyanide plant.

Toronto, Canada.

A Big Lawsuit.—Use of Lignite.—Strike at Cobalt.—Work Interrupted.—Machinery Arriving.—Ore Shipments.

An action for damages amounting to several million dollars, brought by the Dominion Iron & Steel Co. against the Dominion Coal Co., both of Sydney, Nova Scotia, for breach of contract, is now on trial before Judge Lougley at Sydney. The case excites great interest in financial and industrial circles, as many leading financiers and prominent men are involved. The difficulty between the companies arose last fall over the terms of an agreement under which the Coal Co. was bound to supply the Steel Co. with coal for their plant at Sydney. A quantity of the coal supplied was rejected as unfit for steel-making purposes, whereupon the Coal Co. declared the contract at an end and refused to make further deliveries. The Steel Co. claims damages for the loss sustained in the closing down for a time of their plant and for the difference between the contract price and the rate at which they have had to purchase coal from other companies. Repeated attempts have been made to effect a compromise, but without result. The trial began July 30 and the case for the plaintiff was closed on the 8th inst. It was proved by the evidence of officials of the Steel Co. and numerous experts that the coal supplied from No. 6 colliery of the Dominion Coal Co. was unfit for steel-making requirements, being high in sulphur and ash, and full of stone and shale. Analyses made by Arthur P. Scott, the Steel Co.'s chemist, of 123 samples, showed an average of 4.44% sulphur and 12.18% ash, while the breaker coal showed as high as 9.21% sulphur and 38% ash. Important testimony was given by L. McCreith, of A. S. McCreith & Sons, analytical chemists, Harrisburg, Pa., as to the high percentage of sulphur and ash. F. W. Harbord, an English authority on iron and steel manufacture, stated that in the coke used in England there was only about 1% sulphur and 11% ash, and that a larger proportion of these constituents would be attended with risk; where coke high in sulphur was employed in the manufacture of steel rails, it would produce incipient flaws in the steel; the sulphur would cut away the fire bars and destroy the boilers. Frederick A. Foote, of the Illinois Steel Co., concurred with Mr. Harbord as to the danger of using high sulphur coke in the manufacture of rails, and also as to its detrimental effect on the plant. Some of the officials gave strong evidence as to the difficulties of working with the coal supplied and its effects in burning out the grate bars.

The Canadian Railway Commission recently issued an order prohibiting the use of lignite coal on railroads, owing to the danger from sparks, excepting during the winter months. Lignite mine-owners near Edmonton, Alberta, are endeavoring to have the order rescinded and have asked for a hearing. Experts have been sent to Edmonton on behalf of the Commission to make full enquiries.

Mining operations at Cobalt are quiet on account of the strike. Most of the men remaining at work are surface workers and little underground development work is being done. The strike organizers are working among the car-repairers at the Temiskaming & Northern Ontario Railway shops at North Bay, in the hope of inducing a sympathetic strike. There is considerable activity in the bringing in of machinery, large consignments having come forward from the Jencks-Rand Co., of Sherbrooke, Quebec. The Nipissing Co. has received two 125-hp. boilers and the Nova Scotia two of equal capacity. The Rochester mine has got in half of a 12-drill air-compressor and the McKinley-Darragh three 42-sized drills. A number of large orders that cannot be filled for some

time have been forwarded for plant. Five acres of land have been secured at Haileybury for a large foundry and machine shop, the first enterprise of the kind to be started in the district, which it is hoped will be in operation this fall. It will be a great convenience to mine-owners.

Shipments of ore from Cobalt camp for the week ending August 3 amounted to 339 tons from the following mines: Buffalo, 50 tons; La Rose, 52; Nipissing, 173; Nova Scotia, 33; O'Brien, 30 tons of ore.

Calumet, Michigan.

Activity in Building.—Many New Dwellings for Employees.—Centennial-Allouez Mill.—The Baltic Lode in Ontonagon County.—Diamond-Drilling on the Osceola Lode.

Extraordinary activity in the building line is manifested in the Lake Superior copper region this year. Gen-

Map Showing Position of Cobalt and New Districts of Ontario.

eral construction work is heavy and the mining companies are doing a large amount of building. At the Winona work is progressing on 20 new dwelling houses for the use of the company's employees. At the Allouez work was recently started on 25 new dwellings. It is expected that the Centennial will build 25 new houses for its men, the work to begin in a month or two. At the Superior mine, on Section 15, work is under way on five dwellings. The Copper Range Consolidated Co., controlling the Baltic, Champion, and Trimountain mines, also needs additional dwellings for the use of its employees, and will erect several new buildings at the Globe property, where it is developing the Baltic lode. At the Mo-

hawk, work on 11 new dwellings is nearing completion. At the Keweenaw Copper Co.'s townsite, known as Mandan, near the Medora mine, five new single houses, a boarding house, dry and change-house, a school-house, and a residence for the superintendent (A. H. Sawyer) are under construction. These will be completed in a short time. All the foundations and basements are being built of concrete. The Ojibway Mining Co., recently organized, is preparing to erect 35 houses for the use of its employees. Work on the dwellings will not be started until fall. Two buildings of considerable size are now in course of construction. One will be used as a sleeping-house and the other will contain kitchen, dining-room, etc., for the workmen. These boarding-houses will accommodate 40 men. Other structures, necessary to house the temporary equipment that will be required during the mine's development period, will be erected. The Calumet & Hecla is erecting a large brick building for a pattern-shop adjoining its new foundry at Calumet. The roof is being built of structural iron.

A crew of iron workers of the Wisconsin Bridge & Iron Co., is engaged in erecting the superstructure of the three-head addition to the Centennial-Allouez stamp-mill at Grosse-Pointe. The framework is already well advanced and as all the material is on the ground the work will go forward without delay. Two Nordberg stamps have been ordered for the addition and all the machinery for the wash department is contracted for. The other stamp will be installed later, when required. There are now three heads in commission at the Centennial-Allouez mill and with the two additional heads in service the production of the Centennial and Allouez mines can be increased more than 50%. Capt. James Chynoweth, formerly superintendent of the Centennial and Allouez mines and largely responsible for their success, inspected the workings on the new lode at the Lake Copper Co.'s property in Ontonagon county a few days ago. "Whether it is the Baltic lode or not," said Capt. Chynoweth, "is too early to say, but it certainly possesses great value. Its width is tremendous, being 60 ft. from foot-wall to hanging, carrying copper for practically the entire distance. It is a discovery that will add new life and vigor to the people and mines in Ontonagon county." Capt. Chynoweth added that the new lode is situated one mile from the Knowlton lode; intervening are several other lodes that have been opened by the Adventure, but they are of little value.

A diamond-drill has been placed in commission upon the Osceola amygdaloid at the Tecumseh mine, now a portion of the La Salle property. The drill is rigged up at a point 300 ft. north of the old shaft on the same lode and near the boundary line of the Osceola mine. The old Tecumseh company sunk a shaft upon the Osceola lode to a depth of about 2,500 ft., but the formation did not show copper in commercial quantity.

Except for a similar shaft sunk on the adjacent Syracuse property, the concrete shaft of the Pickards Mather & Co.'s Bangor mine (in Ontonagon county) is unique. Cylindrical in shape, with walls four feet thick constructed of cement, reinforced with steel rails and bands, it was put down through an overburden of quicksand and boulders that defied all ordinary methods of sinking. It is impervious to the water of the treacherous ground through which it passes and is so substantially built that apparently it will last indefinitely. Of an inside diameter of 14½ ft., the shaft is equipped with two skiproads and a ladder-way in addition to the necessary space for the piping.

Sunk by sections, the shaft has been dropped eight feet at a time as the sand has been dredged up through a cylinder of steel, and at each stage concrete has been

poured around and into the two forms attached to the steel shoe, creating thus the permanent walls. Little pumping has been required under the process adopted, the water being permitted to remain behind in the shaft, and the use of compressed air was unnecessary until the final stage of the work, when the air-lock in use at the Syracuse shaft was transferred to the Bangor, and while the shaft was entering the rock capping the orebody the water was expelled and held back by pneumatic pressure.

Butte, Montana.

**Progress of Barnes-King Mines.—The High Ore Shaft 2,800 ft. Deep.
—The East Butte Co.—B. B. Thayer on Copper Production.**

The Barnes-King Development Co. properties are being developed into big gold mines. Samuel Barker Jr. was engaged by some of the stockholders to make an examination of the mines and the progress of the work being done by the new company. His report is extremely satisfactory. Mr. Barker says that assays show an immense orebody having a value of \$20 per ton. Pay-ore has been developed for a width of 40 ft. in the Horse Shoe, and the orebody in the Mule Shoe mine will be cut at a depth of about 100 ft. by a two-compartment vertical shaft now being sunk. On the 100-ft. level south of the Barnes-King shaft, another large orebody has been developed, which will be available when the new shaft is completed to a depth of 400 ft. It will take several months to complete the shaft. A great deal of the ore mined now comes from open-cuts worked by the old company. It is the intention to get as much ore as possible from the cuts during the summer while development work is carried on underground. The capacity of the mill is about 300 tons per day, which amount is now being milled, and with the addition of a couple of new vats and a set of rolls the capacity can be brought up to 500 tons per day. The company is doing good work (concludes Mr. Barker) and should begin to pay dividends in the near future.

Sinking has been stopped on the shaft of the High Ore mine, an Anaconda property, the shaft having reached a depth of 2,875 ft. A station is being cut at the 2,800-ft. level; when completed pumps will be installed and cross-cuts run north and south from the shaft to open the veins upon which mining is being done on the 2,200-ft. level and above. The veins have also been cross-cut at the 2,400-ft. level. The High Ore is 300 ft. deeper than the next deepest shaft in the Butte district, and if the High Ore veins are found as large and rich at the 2,800 as they are on the 2,400, an immense tonnage of ore will be added to the reserves of the Anaconda Co. Sinking has now been stopped at all the Anaconda mines and work of a developing character will be confined for some time to lateral workings and connections.

The East Butte Mining Co. is cutting a station at the 900-ft. mark of shaft No. 1, and it is expected that the rich vein of ore cut at the 800 will soon be opened in the station. If the vein is satisfactory at the 900 it may be developed at that point, but whether that is done or not the shaft-sinking will continue, and will be resumed as soon as the station is finished. There has been no limit placed to the depth to which the shaft will be sunk, but it will be taken to the 1,200 or 1,500. In other parts of the mine the development work is making good progress. From the 400-ft. level of the No. 11 shaft, the south cross-cut has penetrated the Yankee Boy vein, which has a width of 60 ft. The entire vein is good concentrating ore, but eight feet of it gives an average assay of 4.5% copper, which is considered a good grade of ore for that depth. The cross-cut between the No. 1 and No. 11 shafts will soon be connected. All the mining that is done in the East Butte ground is done by lessees above the 400-ft.

level, and what ore is taken out on the 400 is extracted by the company in the course of development work. According to Manager Wall the gross earnings of the lessees during July were \$50,000, which, however, included one shipment of concentrate and the output of the precipitating plants. The company gets a royalty of 25% on the gross.

Ben B. Thayer, assistant to the president of the Amalgamated Copper Co., has completed his semi-annual examination of Amalgamated properties in Montana and says that they are in splendid condition. "The improvements in the mines during the last 12 months have been greater than in any like period in the history of Butte, and developments generally have been most satisfactory," he said. "The possibilities of the mines of Butte cannot be estimated, for with the advance of development work the greater are the bodies of ore. The Washoe smelter is treating the largest quantity of ore in its history, but this fact does not mean that the output of the plant in pounds of copper has been increased, for it

the Rio Grande officials have failed to appreciate the rapid growth of the camp. The company has operated one line of road into the camp for a number of years and, last year, a second line was completed; still it is unable to handle the business.

The mills of the Utah Copper Co. are not yet running up to capacity and the Boston Consolidated's plant in the immediate vicinity will not be ready for another month. Up to now the Rio Grande has had a monopoly of the Bingham business, due to a contract entered into several years ago with the Harriman system. But the situation is likely to be relieved by the operators themselves. F. Augustus Heinze, who now figures conspicuously in the Bingham Consolidated and Ohio Copper mines, has such a project in hand.

The miners of Bingham have been discussing higher wages. A committee, representing the Bingham miner's

Montana.

has been the aim of all companies to treat a lower grade of ore. In my judgment the output of copper of the Butte mines will show no increase in 1907 over the output of 1906. I think it is absolutely safe to say that the output of the United States this year will show practically no increase over that of previous years."

Salt Lake, Utah.

Work Curtailed by Lack of Cars.—Railroad Inadequate.—The Yampa Mine.—Shipments From Park City and Tintic.—August Dividends.—News From Park City.—Several Consolidations.

The Boston Consolidated Mining Co. discharged 300 miners who had been employed in its Bingham mines last week. According to a statement made by the management, the reason for taking such a radical step is that the company has experienced difficulty in getting cars in which to move the output of the mine to the smelters. The operating department of the Rio Grande Western railroad was notified some time ago that 25 cars per day could be used. But the railroad company has never filled the order; some days possibly 15 would be sent up to the mine to be loaded with ore; other days, 10; oftener, three or four, or none at all. The mine management has gone to the limit in trying to get service, so it was decided to cut off 300 out of the 800 men employed. The transportation problem is a most serious one at Bingham, and it begins to look as if other means of getting ore to market will have to be devised, for so far,

Utah.

union, waited on the various mine managers last week and asked that the matter be given consideration. The managers informed the committee that owing to the uncertainty of the metal market, the probability of another fuel famine, and the fact that transportation facilities are inadequate to meet the demands of the operators, they could not modify wages. The fact was pointed out that Bingham ores are low-grade and unless handled upon an extensive scale mining in Bingham would be unprofitable. The refusal to consider any increase and the dropping of a large force from the Boston Consolidated mine, has had the effect of putting an end to the agitation and the probability of the occurrence of labor difficulties is now considered remote. The employees at the mines were given a voluntary advance of 10% during the early part of the year, which is to remain effective while copper sells at 15c. per lb. or better.

The Yampa mine at Bingham is one of the best in that camp and, according to advices received from an authoritative source, the net earnings for July amounted to about \$100,000. The ore treated averages 3% copper, \$1.60 gold, and 2 oz. silver. A new reverberatory is being added to the smelter equipment and the project to build a tramway to connect the mine with the smelter will be carried out during the present year, thus improving transport.

During the past week the mines of the Park City dis-

triet shipped 1,169 tons of ore, the contributors and respective amounts being: Silver King Coalition, 621; Daly-Judge, 423; Daly, 62; Little Bell, 63 tons.—Seven Tintic mining companies have declared dividends for August. They are: Colorado, \$120,000; Gemini, \$50,000; Beck Tunnel Con., \$40,000; Uncle Sam Con., \$10,000; Grand Central, \$12,500; Lower Mammoth, \$14,250; May Day, \$8,000.

The Indian Queen and Leland mines in Beaver county have been consolidated in the name of a new company known as the Indian Queen Consolidated. The president is Jesse Knight, of Provo.—At the Salt Lake office of the Nevada Douglas Copper Co. it is stated that the new power equipment recently installed at the mine at Yerington, Nev., will be placed in commission during the present week. Shipments are to be continued as usual from the Ludwig mine recently purchased by the company.—A deal is pending looking toward the consolidation of the West Quincy and Thompson mines at

mine operated in Utah, but has been idle for many years on account of litigation. The mine has been acquired recently by the States Mining Company.

The great task of unwatering the Ontario mine at Park City by the reopening of the Ontario adit, which has been closed for more than two years on account of caves, is being pushed ahead fearlessly. In order to expedite the work and to lessen the danger to men working in the face, the management recently installed pumps at No. 3 shaft, and since starting them a few weeks ago there has been a perceptible lowering of the water in the shaft. The adit has been cleared to a point between shafts No. 2 and 3, but owing to the hazardous character of the work progress is necessarily slow. The management cannot tell how long it will take to make connection between the two shafts and completely drain the mines, although the distance between shafts is a matter of only a few hundred feet.

Denver, Colorado.

Golden Cycle Mill is Burnt.—Activity at Ouray.—Lack of Labor.—Waste of Capital.

On August 7 the Golden Cycle mill, at Colorado City, was destroyed by fire. The disaster was due to an explosion in a roasting furnace. The leaching plant and refinery were saved, but all the buildings are ruined. Ten box cars loaded with ore were also wrecked. This is a disaster to the Cripple Creek district as the plant was treating 750 tons per day and was an important factor in decreasing the current charges for treatment. Originally the plant was known as the Telluride mill and it was bought by its present owners in order to be enlarged and remodeled, under the direction of Philip Argall, of Denver. The cost was \$750,000. It is expected that reconstruction will begin at once.

Later, it is learned that the fire was due to the explosion of coal dust in the fire-box of a roasting furnace. The damage is estimated at \$400,000, which is nearly covered by insurance policies. The general manager, Harvey McGarry, states that milling will be resumed in six months. Meanwhile the ore under contract will be diverted to the Union mill at Florence and the Standard mill at Colorado City.

The El Paso Consolidated G. M. Co. has been awarded the contract for the construction of the Cripple Creek drainage tunnel. This company submitted the lowest bid among a half dozen competitors, its price being \$25 per foot for the entire distance of 15,500 ft. Some of the other bids ran as high as \$42 per foot. It will be remembered that the lowest bid on the first specifications was between \$20 and \$21 per foot, submitted by Lund & Stream, of Cripple Creek, but they threw up the contract after working eight days, as they could not make the specified 300 ft. per month.

Mining developments throughout Colorado continue most encouraging. At Ouray, on the south slope of Hayden Mtn., a large body of ore of good grade has been opened up in the Mineral Farm workings, and what appears to be a continuation of the deposit has similarly been opened up in workings on another property some 1,500 ft. away. The prospects seem bright for large developments. At Rico numerous properties report favorable showings.

A problem of present importance is the lack of efficient labor. From every camp comes the demand for more men. In some places, machine-men at \$5 per day are put on as long as they can do the work at all, no matter how poorly, and the demand is equally great for other classes of labor. This labor shortage is greatly increas-

Sketch Map of Telluride District, Colorado.

Park City.—A syndicate of Utah capitalists intends to construct a railroad into some coalfields in Uintah county. The line is projected to run from Provo to a point near Vernal.

The shareholders of the Northern Light Mining Co. have been called to meet at a special gathering to consider the advisability of consolidating with the Chloride Point and Columbia mines at Mercur. The new company is to be known as the Lion Hill Consolidated.—The Utah Consolidated Mining & Milling Co., the control of which recently passed to a Salt Lake syndicate, has been re-organized and will undertake vigorous development at Tintic.—Ore shipments from Tintic last week amounted to 115 carloads, the contributing mines and amounts being: Centennial-Eureka, 29; Beck Tunnel Co., 9; Colorado, 7; Yankee Con, 4; Uncle Sam Con, 3; May Day, 6; Gemini, 5; Bullion Beck, 9; Ajax, 3; Carisa, 5; Godiva, 2; miscellaneous mines, 3 carloads.

The management of the Newhouse Mines & Smelters Corporation in Beaver county has let a contract to sink the shaft at the Cactus mine below the 600-ft. level. It will be sunk to 1,000 ft.—Material and equipment has been ordered for a mill to be erected at the old Lincoln mine in Beaver county. The Lincoln was the first lead

ing the amount of leasing throughout the State, it being quite impossible in many instances to secure enough men to continue operations on company account. The lure of the Nevada fields is responsible in large degree for the scarcity of men in Colorado.

One of the stock demands of those interested in a mining district is for the investment of more capital. This should be modified to "wisely invested capital." The amount of unwisdom displayed in mining and metallurgical operations is at times appalling. For example, in a district where two smelters have already failed, a third is being built. It is to be a 'pyrite' smelter, regardless of the fact that the ores of the district are zinc-lead ores with subsidiary pyrite and chalcopyrite. In another case an enormous plant was built under the direction of an eminent metallurgist. Before it was entirely completed, his services were dispensed with, and the difficult task of starting operations was entrusted to men who, however capable in their proper sphere, were not of sufficient calibre for the task. To list the cases in which a promising lode opened up by a shallow shaft has been left to start a tunnel a half mile or so long, regardless of the probability that the lode may be barren, pinch out, or fault in depth, or become unworkable in a dozen different ways, would require a volume of the Press. A large part of this blundering arises from the fact that any successful business man believes himself perfectly capable of managing a mine and smelter.

Joplin, Missouri.

Zinc Prices Steady.—Lead Strong.—Output in July.—Several New Strikes.—Successful Leases.—The Value of a Name.

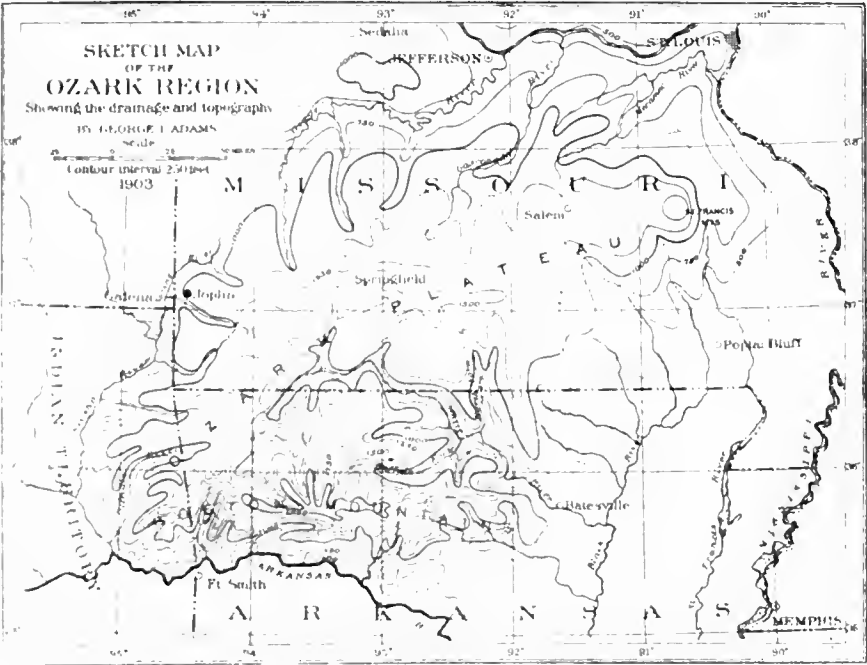

The highest price paid for zinc ore last week was \$5 per ton on an assay price of \$15 to \$18 per ton of 60% zinc. This price ruled the past two weeks, but the two previous weeks of July the basic price was \$46. The metal has been falling all the month, and the wonder is that the price of the ore has fallen so little, but it seems that it is sure to fall off a few more dollars. Lead ore is gradually climbing up, last week selling at \$64 per ton for the top price, while the previous week only showed \$62 as the top; the ruling price, however, last week was \$61 to \$62 per ton. There is a scarcity of labor in the district and at the present time there is an Idaho man here trying to induce men to go West, and no doubt many will go, only to return in a short time.

Shipments.	Zinc, lb.	Lead, lb.	Combined value.
Month of July	17,068,870	5,208,080	\$ 1,220,501
7 months this year	375,073,260	54,852,330	10,063,316
7 " last "	312,347,740	44,543,230	8,117,688
Increase	62,725,520	10,309,100	2,145,628

The Pittsfield Mining Co. is the owner of a rich property in the Prosperity district, consisting of 10 acres of the Chinn land. In sinking the shaft ore was encountered at a depth of 110 ft. and continued for a distance of 10 ft. At present six men are working with two hand-jigs, and a good dividend is being cleared weekly. The company is at present sinking another shaft in order to facilitate the handling of ore, which will be run over a mill to be erected in the near future. —The activity about Carl Junction is attracting the attention of mining

men. A recent strike near the old Lehigh mine, a good one in the early days, is being developed by utilizing steam-shovels, the ore having been discovered almost at the surface of the ground. So far a considerable territory has been stripped and rich milling ore has been mined.

One of the busiest spots in the district is to be found about three miles west of Joplin, in the neighborhood of the Paragon, Iroquois Hero, and Osceola mines. Two years ago this part showed but little development. Since then all these mines have been developed and an upper run of ore worked, but now the lower or sheet-run is being sought for, and with a marked degree of success. George P. Andrews obtained a lease on 30 acres of land having two shafts on it; he sunk one of them to a depth of 170 ft., where he encountered the sheet-run of ore; a mill was erected and much ore has been produced. The Hero has also a distinct run of sheet ore, as three shafts have proved.—The Columbia Zinc Co., owning a 10-acre lease on the Luke land west of Joplin, has a shaft

Map Showing Position of Joplin.

down to 130 ft. The land has been thoroughly drilled, six holes showing a sheet formation.—J. V. Boucher has made one of the richest strikes of recent years in the old Chitwood district. He has a lease on 52 acres on the Glover land, and a drill-hole just completed shows a good vein of ore from the 160 to the 185-ft. level. The company will let a contract for two 300-ton concentrating plants at once.

Thirty years ago James Luke, who owns the Luke land west of Joplin, on which some good mines are now coming into prominence, met a man by the name of Luke and tried to trace a relationship, but failed. A couple of years ago he met Howard Luke, and they, too, tried to trace relationship, and James Luke found his his new acquaintance to be the son of the Luke he met years ago. He became interested in the young man and gave him a first lease on 10 acres of land. The young man leased his land to a company of Pennsylvania capitalists, and they began prospecting it with the result that there is now just about completed a big 300-ton mill, of which Mr. Luke is superintendent, and which it is thought will be in operation by the middle of this month. The royalties from this 10-acre tract will make him a fortune. —All the mines in the Badger-Peacock district that were completely inundated on May 13 will be in full operation again by next week. This will add 300 to 350 tons of ore to the weekly output.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A ROUGH estimate of the amount of water required to sluice sand out of leaching vats, is 100 gal. water per ton of tailing.

BESSEMER STEEL is steel made by the bessemer process, irrespective of whether its carbon content is high, low, or intermediate.

PUMPS ordinarily should not have a piston travel of over 100 ft. per min., and for continuous boiler feeding service a little less than half that speed is recommended.

GRAY PIG IRON and gray cast iron is pig iron and cast iron in the fracture of which the iron itself is nearly or quite concealed by graphite, so that the fracture has the gray color of graphite.

IF the height of a tank is known, to find the diameter required for any given capacity, divide the cubic capacity desired by 0.0034, divide the remainder by the height in inches and extract the square root. The quotient thus obtained is the diameter in inches.

IF A PUMP is giving trouble, it is usually advisable to leave the steam end alone, and look to the water end or the suction pipe for the cause. The steam valves probably do not need changing, but the water valves may need resetting, and the water piston repacking.

IT is generally best to place a pump as near the water supply as possible, as the atmospheric pressure alone forces the water into the pump, and consequently the lower or shorter the lift, the faster, and with greater efficiency will the water be delivered to the pump.

CONDENSING ENGINES require from 20 to 30 gal. water, at an average low temperature, to condense the steam represented by every gallon of water evaporated in the boilers supplying steam to the engines, that is, about 1 to 1½ gal. condensing water per minute per indicated horsepower.

IF A PLACER CLAIM was located in April, 1906, and no assessment work has been done upon it, the locator has still the whole of the calendar year 1907 in which to perform the assessment work. If on January 1, 1908, the work has not been performed—and the locator is not, at the usual working hours of that day, in possession—the claim is subject to re-location.

FOR the treatment of silver ores by hypo-sulphite solution, it has been the general practice where gold is contained in the ore in some quantity, and especially in an arsenopyrite ore, and where salt is cheap, to use as high as 12% of salt. In this way the extraction will be high in gold as well as in silver and the resulting sulphides will be cleaner and of higher grade. As a general rule it is desirable to crush dry, and not finer than 30 mesh.

THE Standard group of mines at Bodie, California, has produced in 25 years, \$14,500,000, paying \$5,000,000 in dividends. On the other hand, this output has been mined (almost wholly above the 1,000-ft. level) from a system of more than 100 veins, ranging in thickness from 0.5 in. of specimen rock to 30 ft. of clay and quartz; distributed through a zone about 2,000 ft. in width, and representing from three to five distinct periods of formation.

MERCURY, arsenic, antimony, and tin form each two stable classes of salts. Therefore, the lower oxides, chlorides, etc., of these metals act as reducing agents, and their higher oxides, chlorides, etc., as oxidizing agents, each to the extent of its chemical force. Arsenic, antimony, tin, molybdenum, and several of the rare metals of these groups enter into acidulous radicles, which form stable salts. Arsenic, selenium, and tellurium are metalloids rather than metals, while arsenic, antimony, and bismuth belong to the nitrogen series of elements.

NICKEL does not cast well in the pure state, as it absorbs carbon monoxide and then gives it out on cooling, thus causing blow-holes. This difficulty is overcome by the addition of a small quantity of magnesium—about one-eighth per cent. Aluminum and phosphorous have been suggested for the same purpose. Copper and nickel alloy readily in all proportions. When added to copper it affects the color but slightly. Until the alloy contains about 30% of nickel, the coppery color is still distinguished, but when the proportion of nickel approaches 40%, the alloy becomes silver white, and continues unchanged in color until the nickel reaches about 80%, after which the color darkens considerably. Copper-nickel alloys are rarely used, except for coinage. German silver includes a large number of alloys containing copper, nickel, and zinc in different proportions, sometimes with the addition of other metals.

THE provisions of the Nevada statutes on the subject of work necessary to be done to perfect a lode mining location are as follows: "The locator of the lode mining claim must sink a discovery shaft upon the claim located, four feet by six feet, to the depth of at least ten feet from the lowest part of the rim of such shaft at the surface or deeper, if necessary to show by such work a lode deposit of mineral in place; a cut, or cross-cut, or tunnel, which cuts the lode at a depth of ten feet, or an open cut along the said ledge or lode, equivalent in size to a shaft four feet by six feet by ten feet deep, is equivalent to a discovery shaft."

This work is to be done within ninety days of the date of posting the location notice. There is no statutory rule requiring the discovery to be in the centre of the claim, but the U. S. Surveyor General for Nevada, requires it as a condition precedent to the approval of survey for patent.

THE Lake Superior region, which includes five mineral ranges in States bordering upon the great inland sea, continues, by augmented annual outputs, to outrank all other known deposits in supplying iron ores. In the year 1905 its production was 33,325,018 long tons. The mines which compose the five ranges of the Lake Superior region contribute more than three-fourths of the total iron ore mined in the United States, and up to a year ago this region has supplied an aggregate of over 300,000,000 long tons of iron ore. Of this quantity the Marquette range in Michigan, which has been producing since 1851, had shipped 77,000,000 long tons; the Menominee range, in Michigan and Wisconsin, had, since its opening in 1877, furnished 53,500,000 long tons; the Gogebie range, in Michigan and Wisconsin, opened in 1884, had shipped 47,000,000 long tons; the Vermilion range, in Minnesota, opened also in 1884, had supplied 23,500,000 long tons; but the phenomenal shipments have been from the Mesabi range in Minnesota, which since 1892 have reached a total of 99,000,000 long tons, or nearly one-third of the ore obtained from the Lake Superior region.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Slag Dam.

The Editor:

Sir—I am in receipt of your letter of July 16, making inquiry as to a certain dam near Helena, made of smelter slag. This undoubtedly refers to a slag dam which was built at the East Helena plant of the American Smelting & Refining Co. about eight or nine years ago.

Nothing was used in the construction of this dam but slag from the lead blast-furnaces. The object was to back up the waters of Prickly Pear creek so as to form an artificial lake for storage purposes. A trench cut about 4 ft. wide and 4 or 5 ft. deep was first dug across the site of the proposed dam, the object being to form a heart-wall down to water level so as to minimize the danger of the water leaking through at the bottom of the dam. Molten slag from the furnaces was simply poured into this trench and then over the entire surface of the ground at the proposed site of the dam, making a solid wall 200 or 300 ft. wide and 20 to 30 ft. deep. This dam has, of course, gradually been widened as the necessity for providing additional space to dump our slag increased. At the further end of the dam arrangements were made for taking care of the surplus water by building a spillway of concrete with the usual gates for controlling the water.

We have found that this slag makes a good dam and we have had very little trouble with it since it was constructed. Owing to the brittle nature of blast furnace slag and its tendency to crack, there is, no doubt, more or less seepage through this dam, but it is not enough to cause any serious trouble.

East Helena, Montana, July 30.

Tube-Mills at Guanajuato.

The Editor:

Sir—As to our experience with our tubes: Apparently it has been markedly different from that of a good many people, and we really do not understand the reason why, as we have had no difficulty whatsoever, aside from routine replacements in the eight or nine months we have been running them. These mills, as you know, are the Abbé mills, 4 ft. 6 in. by 20 ft., and are handling about 80 tons of pulp per day.

A screen test made on pulp going to the tube-mill shows:

	Mesh.	Per Cent.
Remaining on	40	11.2
"	50	11.2
"	60	8.9
"	80	18.6
"	100	16.3
"	120	26.1
Passing	120	9.7

Moisture 60%.

The screen test on discharge-pulp shows:

	Mesh.	Per Cent.
Remaining on	10	0.5
"	50	1.7
"	60	2.9
"	80	6.0
"	100	16.2
"	120	21.8
Passing	120	51.2

Mechanically the mills have given us no trouble since their installation, with the exception that the first pinion shipped with the mills was shrouded and the distance between the shrouds was not sufficient to allow for any end motion whatsoever of the mill as a whole, and the gear ultimately rode the shroud of the pinion, smashing

both the gear and the pinion, but doing no further damage; since replacing with a pinion wider between the shrouds, no difficulty whatever has been had.

To limit the end motion upon this type of mill, two guide-rollers with vertical axis bear upon the sides of the supporting tire next the gear end, and a good deal of trouble has been had by earlier users of the mill, we understand, on account of the tendency of the mill to run endwise, being so severe that these guide-rollers were quickly worn out; the Abbé Company suggested to us, before our first mill was installed, that it was possible to cant the friction-rollers upon which the tire moves (and which constitute the support of the mill) in such a way as to cause the main tube to go in either direction longitudinally, and that by delicate adjustment of this canting, it should be possible to confine the mill entirely to one position without its bearing unduly hard on either of the guide rollers. We experimented with this and within the first day or two after the mill was started we found it possible by this adjustment to cause the main tube to 'float' entirely free on its supporting rollers without touching either of the guide-rollers at all, and the mill ran for three months at one time without touching either guide-roller, and normally it hardly touches them once a day.

The silix lining of the mills has given good satisfaction, the first lining running eight months before it had to be replaced, though at the end of about six months, three or four defective blocks were replaced, with a two days' shut-down.

A great deal depends apparently upon the truth of the supporting tires and the homogeneity of the material composing it, because if in these tires the slightest irregularity occurs, either as an original defect or as the result of operation, bumping would rapidly ensue, which would cause the destruction of the mill and perhaps its foundations. So true is this that we found on starting the first mill, that a film of $\frac{1}{16}$ of an inch of sand, which had accumulated on certain oily spots on the tire, caused violent bumping, until the mill was stopped and the ring tire carefully cleaned off. We keep these tires at all times carefully cleaned and a little oil is put on the surface of the tire once or twice a day. Since the tires were first cleaned, there has not been the faintest bump or vibration evident about either mill, the mills running as quietly and smoothly as possible. The mills are kept filled slightly above centre with pebbles, the pebble wear being approximately $\frac{1}{4}$ lb. per ton of ore treated; silix linings wear eight months; power to start the mill, about 60 hp., which immediately drops to 43 hp. as soon as at running speed.

Trusting that the above data may be of interest to some of your readers.

C. W. VAN LAW.

Guanajuato, Mexico, July 14.

Absurdities of Promotion.

The Editor:

Sir—The absurd statements of mine promoters' literature receive occasional notice in your columns, but these writers of lurid fiction must draw more freely upon their imagination or else yield the palm to one E. G. Lewis, editor of the St. Louis *Woman's National Daily*. In the July 20th issue of that publication this veracious writer, in a signed editorial under the caption 'Gold as Money,' makes the following statement:

"A single reef in the strand in Africa is known to contain enough gold to give every person in the world \$30,000, the only question being how fast it shall be produced, a question of machinery and labor."

As the population of the world is usually estimated at

1,400,000,000, this reef in the African "strand" (whatever that may be) is "known to contain" \$42,000,000,000,000! Shades of Letson Balliet, Dr. J. Grant Lyman, and all others of that fraternity, arise and salute your chief! With one sweep of his facile pen this guileless and untutored Missouri editor establishes a high-water mark for 'ore in sight' that must make the most imaginative promoter gasp with admiration and turn green with envy.

What a waste of good raw material it seems when we contemplate an individual who can thus dip his pen in the colors of the rainbow writing platitudinous homilies for a woman's paper! Really, it's too bad. Cesar a nursemaid or Napoleon a goosherd could hardly present an illustration of a greater misfit. Mr. Lewis should abandon petticoat journalism and give his talents fair scope by opening an Eastern office for the promotion and sale of Western mining stock.

AUBREY L. WISKER.

Winnemucca, Nevada, July 22.

A Fundamental Problem.

The Editor:

Sir—A question involved in your editorial of June 29 has probably presented itself in various forms to many people, and a general discussion should be interesting. Undoubtedly, there is rather a wide-spread idea among men who have dipped into the mining business without knowing much about it, that it is "not possible to employ experts that will give concrete advice as to what to do and when to do it," and that "mining is only a gamble after all." As to this particular case, the key to the correct solution is probably given in your first paragraph, when you say: "Finally, two mining engineers of experience were engaged," who reported unfavorably on the properties. Had they been engaged 'firstly' instead of 'finally,' these brokers and their clients would probably have been saved some money and a good deal of mental wear and tear.

One mistaken idea that many men seem to have, is, that good properties are to be had for the asking. That it is only necessary to get a little money together, send a man out into the field, and have him come back shortly, loaded with choice embryonic mines. They expect him to do this with as much ease and celerity as they expect the bell-boy in their hotel to bring up a high-ball, in response to the touch of a button. As a matter of fact, men who follow the mining business are always on the lookout for good properties. Every engineer has visions of some day getting hold of 'something for himself.' Thus the mining districts, and every conceivable spot, to the ends of the world, are constantly being scoured by an army of keen-eyed, clear-brained, carefully-trained men, each looking for something good, and looking for himself, which guarantees that his heart is in his work. In addition to these men there are the representatives of hundreds of big syndicates and exploration companies, whose business it is to go over the surface of the earth with a fine-toothed comb, from the poles to the equator and back again, always hunting for desirable properties, promising prospects, or good indications. The zeal of these men is only second to that of the individuals operating independently, and they have practically unlimited capital behind them. And yet every day we see men who have made a competence in their calling and feel that they have a little loose money with which to do as they please, deciding to form a pool or a syndicate and get hold of some good mining properties. Then if they go into a boom camp and finker around in three or four different spots out on the wash, or run a 100-ft. tunnel into a volcanic plug somewhere, spend a

few thousand dollars, and fail to develop a Robinson or a Homestake, we hear a great howl against the profession of mining engineering; they forget that it costs money to make a mine, even after you get a good prospect, that many a good prospect has been spoiled by sinking on it, and that even fair prospects are rare.

It may be that these brokers made the serious mistake of suddenly deciding that they wanted to own a mining property, and wanted it quick. This is probably where a great many promoters, with the best of intentions, fall down at the start, because a cheap man, sent out with instructions to get a property, and to get it quickly and cheaply, has not much latitude in which to work, and must choose the least undesirable of the claims that he sees. If he exercised his judgment to the extent of returning with a report that there was no good ground available, and that he would not recommend the purchase of any claim, the impression would be either that he had not done his work thoroughly, or that he was mistaken, and another man would be sent out with positive orders to find something. Of course, it is out of the question for a small concern to secure the services of an expensive man to do the preliminary searching for a property. Therefore, they get either an inexperienced man, possibly in the shape of a young college graduate, who is still brimming over with youthful enthusiasm and untarnished optimism, or some 'practical' man who can polish a spot the size of a ten-cent piece on the end of a drill, but who is entirely incompetent to pass judgment on a proposition of this kind.

If a man with experience and training is consulted, it is generally after most of the available funds have been spent, and the brokers want to know whether to 'throw up the sponge' or 'reorganize,' both of which procedures are about equally lucrative to the investors.

In deciding upon a man to examine a property lying in a new camp or one undergoing a boom, it is almost always advisable to send an outsider, even though it costs a little more. The reason for this is that the men on the ground are too often imbued with the boom spirit, and are unduly sanguine. Also the fever of stock speculation often warps otherwise sound judgment, and it will be found that many of these men have private interests to further. Anyway, as our standards are all relative, at best, the tendency will be for them to judge your property by comparison with others in the camp, all of which may be of questionable worth, and to pass upon the valuation on the basis of what other properties near it are bringing, irrespective of its real value. Another curious trait that engineers often discover in clients of this kind, is an aversion to receiving an unfavorable report. After they have spent a few thousand dollars on a property, they are inclined to consider it as a personal affront when the engineer tells them it is worthless. They do not like to be waked from their pleasant dreams of easy money and big profits. Many men seem to reason that if they stop work and abandon the property, the money they have put in will be a dead loss, while if they keep on gophering around they may strike something or something may turn up—perhaps a purchaser or a new boom. In other words, after the men own the property and some money has been spent, it will take three men to convince them that it is better to stop, where one man can persuade them to continue. The best advice as to what engineer to employ for the final decision can be had from some one in the profession. If these brokers knew no mining man upon whom they could rely for an examination or for such advice, they must have been strangers to the mining business and could hardly expect to win.

San Francisco, July 22.

The Relation of Ore-Deposition to Physical Conditions.

BY WALDEMAR LINDGREN.

*It is well known that chemical reactions under ordinary surface conditions differ widely from those which prevail at great depths. Heat increases gradually below the surface until temperatures of potential rock fusion are attained, and pressure undergoes a corresponding increase. The normal increment of temperature and pressure with depth can rarely, however, be separately considered, for intrusions of molten masses of rock may locally carry temperatures of abyssal depths closer to the surface, and at the same time increase the pressure far above what is normal for any given depth. Whenever, therefore, reference is made to deposits formed at great depth this reservation must be borne in mind.

In speaking of ore deposits of varying depths the discussion always refers to the vertical distance from the points or levels under consideration to the surface of earth at the time of genesis, which involves, of course, the possibility of at least an approximate estimate of the amount of erosion that the deposit has suffered since its initial formation, and of the geological epoch during which this formation took place.

It is significant that ores deposited in ancient eras often differ markedly from those of more recent times—and especially is this true of the ores of pre-Cambrian times; but these differences are largely accounted for by a deep erosion which has laid bare deposits formed at great depth. Moreover, since their genesis, the latter have been subject to many changes by rock-pressure and by the action of solutions.

Evidence of the genesis of metallic ores by hot waters has accumulated rapidly in the last few years. It is believed by many geologists that these hot waters were of magmatic origin. Possibly the zeal of the advocates of this view may carry them too far, and it is by no means denied that important ore deposits may be formed by sedimentary processes or by cold or hot circulating waters of atmospheric origin. No special attempt will be made in this place to advocate the deposition of ores by magmatic waters, although the probability of such an origin will be indicated as a corollary from the classification herein outlined. Little emphasis will be laid upon the form of the deposits, as that is chiefly due to the various physical and chemical conditions of the rocks through which the hot solutions found their way.

To the mode of deposition in open cavities a few words may be devoted. It is universally conceded that open spaces of desiccation and solution may easily exist down to a depth of many thousands of feet below the surface. The hydrostatic pressure due to gravity will to some extent counteract the rock pressure and help to keep fissures open.

But it is undeniable that in many abyssal ore deposits formed at very great depths below the surface veins are found which are undoubtedly due to the filling of rather large open cavities, which it is very difficult to conceive as having remained open under the tremendous pressure prevailing. An explanation has been sought in the force of crystallization; it has been supposed that this force would be great enough to force the walls apart. Still, it seems scarcely possible to attribute such power to it as would be necessary to force deep-seated crevices apart to form room for the crystals, and another strong objection is that it would seem impossible that under

these conditions comb structure and coarsely even-grained quartz could be produced.

L. C. Graton, in his recent studies of the gold and tin deposits of the southern Appalachians, has another explanation which is more likely to be the correct one. According to him, the solutions which are of magmatic origin are under exceedingly heavy pressure in the deeper part of the crust, gradually diminishing as they ascend toward the surface, and this pressure, intimately related as it is to the tension of the intrusive magma from which the water is given off, would be abundantly sufficient to open the crevices to cavities and to allow undisturbed crystallization of the mineral substances dissolved in it. The magmatic solution would be essentially similar to magma intruding into dikes or to pegmatites crystallizing into hot granitic rocks; the pegmatites sometimes show most excellent comb structure, and their closed structural relationship to certain classes of ore-bearing veins is one of the points substantiating the hypothesis explained above.

Few conceptions have caused greater advance in the study of the crystalline schists than that of gradually changing zones, each characterized by certain minerals stable under the conditions obtaining. The same principle is applicable to the ore deposits. The watery solutions ascending through the earth's crust are subject to constantly changing pressure, temperature, and mass conditions; certain minerals stable, for instance, under very high pressure and temperature, can no longer exist under conditions prevailing near the surface. By careful consideration of geological conditions it becomes possible, in most cases, to decide whether a given deposit has been formed at the surface, at moderate depths, or at a very great distance below the surface. Certain minerals have then their 'critical level' which they cannot leave without falling prey to decomposition, while certain other minerals have such a large interval of existence that they may be classed as 'persistent' minerals.

Upon comparing the mineral records of ore deposits found at various levels of the earth's crusts, with the results obtained by students of general metamorphism, it very soon becomes apparent that the same laws do not apply to both cases, although there are many points of similarity. The reason for this is not difficult to find. In metamorphism one deals with small quantities of solutions, as a rule, free from large amounts of carbon dioxide and sulphide of hydrogen. The ore deposits, on the other hand, were formed by large quantities of waters rich in these gases, heavily charged with alkaline carbonates, and ordinarily of a high temperature. A large number of silicates, and other minerals, fairly stable under the influence of ordinary deep ground-water, are incapable of existence in most vein-forming solutions. Biotite, amphibole, soda-lime feldspars, often also chlorite and serpentine, as well as magnetite, are included among these. Under high pressure and temperature many of these minerals prove stable, however, and are even formed by metasomatic processes in the veins. In the contact metamorphic ore deposits, formed under very high pressure and temperature, a new set of minerals will develop, some of which are especially characteristic for these occurrences.

Phenomena of stress are in most cases excluded during the formation of ore deposits; static conditions and hydrostatic pressure prevail.

The mineral deposits described below occur almost without exception in or close to masses of igneous rocks. For the pegmatites and contact metamorphic deposits this is self-evident, both classes being associated with bodies of rocks intrusive into the crust at varying but generally great depths below the surface. For several

*Abstract from paper read before the Mexican meeting of the International Geological Congress, September 10, 1905. Published in *Economic Geology*, Vol. II, No. 2.

classes of veins a similar relationship to intrusive rock masses has been proved. In typical examples the intrusive body—which may be a granular rock or a porphyry—is surrounded by an aureole of contact metamorphic deposits of lead and copper, but usually poor in the precious metals. Fissure veins bearing gold and silver are either contained in the igneous rock itself or in its immediate surroundings.

The veins in the pre-Cambrian rocks have in many places in the United States been demonstrated to have a pre-Cambrian age. Many geological conditions indicate that these deposits have been formed at great depths below the surface, and here, too, as a rule, a relationship to intrusive rocks can be shown.

There is still another and large class of veins carrying gold and silver which cut through volcanic flows of Tertiary or later age. In these we are enabled to fix the level of deposition with greater accuracy, and often it can be demonstrated by geological or physiographical considerations that a given deposit was formed only a few hundred feet below the original surface of the lava flow. Lastly, the orifices and sinters of the hot springs so abundant in these volcanic regions may be examined and the minerals here formed may be compared to those of veins and other deposits known to be formed at much greater depths.

The ore deposits discussed in this paper may be divided into three main classes:

1. Ore Deposits Consolidated From a Molten Magma.

Characteristic Minerals.—Magnetite, ilmenite, chromite, pyrrhotite, chalcopyrite, pyrite (?), pentlandite; they contain copper, nickel, and cobalt, but are very poor in gold and silver. Platinum is sometimes present. Accompanying gangue minerals are those of basic or acidic igneous rocks.

2. Ore Deposits Made by Aqueo-Igneous Solutions.—Pegmatite-Dikes.

Characteristic Minerals.—Magnetite, bornite, arsenopyrite, molybdenite, cassiterite, wolframite.

Accompanying Gangue Minerals.—Quartz, muscovite, alkali feldspars, tourmaline, apatite, fluorite, spodumene, more rarely hornblende, soda-lime feldspars, et cetera.

These deposits contain very little gold and silver and are very rarely economically important except for tin ore, and minerals of the rare metals. Metasomatic action of the solution on walls of crystalline rocks is usually slight, though tourmaline and cassiterite may develop in the surrounding, usually granitic, rock. Pegmatite formation evidently requires a high temperature and the conditions are decidedly deep-seated. The solution has a tendency to take up substance from the wall-rock which may become part of the pegmatite and crystallize as garnet, zoisite, andalusite, staurolite, and feldspars. Pegmatite veins may gradually change into quartz veins, but no transitions have been satisfactorily shown to exist between these and the gold-bearing fissure-veins. At many contacts of intrusive rocks not characterized by pegmatites, quartz veinlets abound and often carry crystallized specularite.

3. Ore Deposits Made by Aqueous Solutions.

A. OF DEEP-SEATED ORIGIN.

(a) ORE DEPOSITS DUE TO CONTACT METAMORPHISM OF SEDIMENTS BY INTRUSIVE IGNEOUS ROCKS.

Characteristic Ore Minerals.—Magnetite, specularite, pyrite, pyrrhotite, bornite, chalcopyrite, zinc blende, galena, molybdenite. (Complicated sulpho-salts, antimonides, tellurides, etc., are absent.)

Gangue Minerals.—Andradite and grossularite-garnet,

epidote, pyroxene, wollastonite, ilvaite, actinolite, spinel, diopside, calcite, quartz, scapolite, apatite, and tourmaline. Biotite and muscovite, though occurring in contact metamorphic argillaceous rocks, are not common in the ore deposits. These deposits, which are almost exclusively of metasomatic origin, are apparently caused by replacement of calcareous rocks by very hot solutions given off by the cooling magma. These solutions were probably above the critical temperature and thus really in gaseous condition.

The deposition is, as a rule, confined to rocks on which the solutions exerted a strong chemical action.

The majority of contact metamorphic deposits are poor in gold and silver.

(b) CASSITERITE VEINS.

Characteristic Minerals.—Cassiterite, pyrite, arsenopyrite, specularite, quartz, tourmaline, topaz, lepidolite, muscovite, apatite, fluorite, and wolframite; calcite and siderite are not abundant.

The metasomatic processes along the veins are intense and result in the conversion of granites, crystalline schists and slates into often coarsely crystallized quartz, tourmaline or quartz-topaz-muscovite rocks.

The metasomatic action on limestone and clay slates is not known.

Feldspars and dark silicates are not stable but are replaced by the minerals mentioned; quartz is re-crystallized. The changes in chemical composition are not extensive, as far as known, and no great concentration of potassium, so frequent in other classes of veins, is observed. Fluorine, boron, and many of the rarer elements are introduced.

The occurrence is as veins in and around intrusive masses of normal granite rich in soda.

(c) APATITE VEINS.

Characteristic Minerals.—Apatite and other phosphates, scapolite, diopside, hornblende, biotite, specularite, and pyrrhotite. Strong metasomatic action of the country rock is the rule and results in the development of scapolite, replacing soda-lime feldspar, and of malacolite replacing limestone. The introduction of chlorine or fluorine is characteristic, but the metasomatic processes are not known in their chemical details.

The occurrence is as veins following fissures or contraction joints in or about basic intrusives. High pressure and temperature are probably necessary for the genesis of these veins, which are poor in gold and silver.

(d) GOLD AND SILVER-BEARING VEINS.

The deep-seated veins containing gold and silver, with which are usually associated other metals in varying amounts, form a most important class, to which the larger proportion of the world's production of gold, and much of its silver, is due. They constitute a series with gradually changing characteristics, impossible to separate in sharply defined subdivisions.

The first group to be discussed is found in pre-Cambrian formations in various parts of the world. All geological indications point to their formation at great depths under heavy pressure and at high temperature. They are not entirely confined to these oldest formations, but also appear at places in more recent rocks wherever igneous intrusions have created the necessary special conditions of temperature and pressure.

Characteristic minerals are gold, pyrite, pyrrhotite, galena, zinc blende, magnetite, specularite, ilmenite, quartz, biotite, tourmaline, garnet (pyrope), hornblende, chlorite, apatite, spinel, and epidote. Calcite is also present in small amounts. The replacement of the country rock is usually strongly marked; amphibolites and

micaceous schist are replaced by tourmaline, garnet, a green biotite, and epidote. The presence of apatite, magnetite, and ilmenite is noteworthy. Soda-lime feldspars are unstable under the influence of the vein-forming solutions, and alkali-feldspars do not form as a rule. There are no data as to the changes effected in limestone or argillaceous rocks, as the veins have not been observed in such surroundings.

The veins occur in, or close to, granite intrusive in schist.

In certain veins of this group sericite forms together with biotite and transitions obtain to the most common type of gold and silver veins, namely, the sericitic and calcitic type, which is so abundantly represented throughout the Cordilleran region in the vicinity of deep-seated intrusions in rocks ranging in age from pre-Cambrian to Cretaceous. Though usually appearing as fissure veins, the deposits very often assume an irregular or bedded form wherever the containing rocks are easily soluble. Pressure and temperature must have been moderately high and the depth below the surface several thousand feet, as a minimum. All of these veins have been exposed by deep erosion and their epoch of formation can, in most cases, be shown to have closely followed the particular intrusion with which they are associated.

The principal minerals are: Gold, pyrite, chalcopyrite, arsenopyrite, galena, zinc-blende, molybdenite, tellurides, tetrahedrite, often the mercurial variety; more rarely pyrrhotite and cinnabar. As gangue minerals appear quartz, calcite, dolomite and siderite, sericite, sometimes chlorite, barite, and fluorite. The carbonates increase in quantity compared to the previously described class of veins. Absent or very rare are magnetite, specularite, hornblende, garnet, epidote, tourmaline.

A fairly thorough examination of the metasomatic conditions of this class of veins has been made. In ordinary igneous rocks almost all of the rock-forming minerals are unstable under the influence of vein-forming solutions of this kind. The list of unstable minerals comprises, among others, orthoclase, microcline, soda-lime feldspars, nepheline, amphiboles, pyroxenes, epidote, magnetite, ilmenite, and titanite. Chlorite is, as a rule, ultimately decomposed, although somewhat away from the veins the first step of alteration by the solutions, here robbed of most of their active constituents, consists in a chloritization. In a few veins chlorite is capable of recrystallization with quartz. Quartz is on the whole stable but under the influence of solutions heavily charged with carbon dioxide a replacement and re-deposition of quartz by calcite, dolomite, or siderite occurs. The two processes of carbonatization and sericitization prevail, and almost all of the original minerals are subject to them. Either one may quantitatively prevail according to the local composition of the solution. Carbonatization turns all or a large part of the iron, manganese, magnesia, and lime of the rock into carbonates. Complete sericitization transforms the rock into a mixture of feldspar, sericite and quartz and is usually accompanied by a removal of the iron and earthy bases, due to lack of carbon dioxide to fix them.

Titanite is altered to rutile and calcite; magnetite often to siderite; ilmenite to rutile and siderite. The only feldspar which approaches stability is albite. In rocks very rich in albitic, like the amphibolites of California and Western Australia, only a smaller amount of sericite forms; the albite is dissolved and re-deposited with quartz and carbonates either as filling or as product of replacement. Apatite appears stable but is not formed as an original vein mineral as is the case in the more deep-seated deposits. Pyrite replaces, in varying quantities, almost all of the rock-forming minerals, but espe-

cially those rich in iron. Gold and most of the heavy metals penetrate the country rock only with difficulty and are deposited in the open spaces, if such are available. Silicification of the wall-rock is a rather local and exceptional mode of alteration, as ordinarily the wall-rock acts as a semi-permeable membrane which does not admit the colloid solution of silica, while gases and salt solutions may easily permeate it. When silicification takes place it is usually due to mass action of surrounding shattered or porous silicious rocks.

Clay slates consisting of quartz and sericite are very little affected by the vein-forming solutions, but in shattered rocks of this kind a silicification often takes place. The same is often true of sandstones. In both, pyrite is apt to form in abundance. Clay shales consisting of quartz, feldspar debris, glauconite, and kaolin are a little more affected and often suffer carbonatization, sericitization, and pyritization.

The effect on calcareous rocks is of particular interest, and very different from the processes just described. In some veins which are closely related to intrusive bodies, such as the pyritic veins of Clifton, Arizona, it has been found that the impure limestone adjacent to the veins alters to tremolite or diopside, with which are associated pyrite, magnetite, and some epidote. The same vein solutions sericitize the monzonite porphyry of the district.

But in by far the majority of cases the pressure and temperature do not appear to reach the requisite point for the metasomatic development of these minerals. Ordinarily the limestones are simply silicified to fine grained jaspery rocks, or transformed into dolomite. Calcareous rocks are easily penetrated by solutions of heavy metals, and hence the metasomatic development of pyrite, zinc-blende, galena and chalcopyrite in them is extensive and important.

B. ORE DEPOSITS FORMED AT SHALLOW DEPTHS.

In the Cordilleran regions, as well as elsewhere in the world, veins containing gold with much silver, and, more subordinately, lead, zinc, and copper, are found in flows of volcanic origin. In very many cases the geological conditions enable us to say with considerable certainty that these deposits have been formed at a relatively slight depth below the surface, say from a few hundred to four or five thousand feet below the actual surface of the ground, at the time of mineral deposition. Among these are, for instance, most of the veins of western Nevada, the San Juan region of Colorado, Cripple Creek, and a great many ore deposits of Mexico.

These deposits are closely related to the sericitic and calcitic veins formed at greater depths which were described in the preceding paragraph. An unbroken line of transition between them may in fact be found, but at the same time veins formed at slight depth possess certain characteristics of their own which will be briefly described.

Gold and silver prevail, though compared to the deep-seated veins with quartz gangue there is more silver, and the native gold is, as a rule, present in much more finely divided form. Pyrite, galena, zinc-blende, chalcopyrite, arsenopyrite, argentite, and stibnite are the prevailing ore minerals, but more complex sulphides, sulph-antimonites, and sulph-arsenites, such as ruby silver, stephanite, polybasite, etc., are more abundant than in deep-seated veins. In part their presence may be due to a secondary enrichment by descending solutions, but opinions do not as yet agree regarding all of these occurrences. Of gangue mineral quartz prevails, but it is here often accompanied by chalcocony, opal, or other

forms of silica. Calcite and dolomite are moderately abundant in the vein-filling, while siderite occurs more rarely. Barite and fluorite predominate locally. Magnetite and specularite, as well as the whole line of the silicates belonging to the greater depth of formation, are absent. Apatite is of rare occurrence. On the whole, as may be expected near the surface, the filling of open cavities is a process of much importance.

The metasomatic processes differ, in character of course, in different country rocks. In igneous rocks of medium acidity a strong sericitization is apt to take place immediately adjoining the vein with attendant concentration of potassium and leaching of lime, iron, and magnesia. Pyritization is also of common occurrence. The solutions appear to have been poorer in carbon dioxide than those of the deep-seated deposits, and extensive carbonatization is therefore less common. On the other hand, the solutions have a tendency to spread from the veins through large areas of adjoining rocks, probably owing to more extensive fissuring near the surface, and here, robbed of their most active ingredients, they produce the so-called 'propylitization,' which consists in the development of chlorite and epidote, as well as pyrite, from the dark silicates, and in the eventual degeneration of the feldspars into quartz, chlorite, and epidote.

In very basic rocks this propylitization may proceed closely up to the veins, but as stated above, sericitization is likely to take its place. Complete silicification of the wall-rock is more common in these deposits than elsewhere. In large altered areas irregular masses of completely silicified rocks are often met with. These products of replacement are usually dark gray or brown, and fine grained, flinty or cherty rocks. Silicious rocks like rhyolite are especially subject to this irregular silicification.

In calcareous rocks the products of replacement along these veins are usually fine grained quartz or chalcedonic jaspers and cherts.

The majority of cinnabar deposits — whether in veins or irregular masses — are also formed at no great depth below the surface. This does not imply that mercury is only precipitated near the surface, as advocated by some, for many of the ore deposits of the deeper zones contain this metal, occasionally as cinnabar, but more frequently as mercurial tetrahedrite or as telluride of mercury (kalgoorlite). The principal ore minerals of cinnabar deposits are, besides that substance, marcasite, pyrite, stibnite, all minerals susceptible of formation at slight depths. The metasomatic action on serpentine and other basic rocks consists in carbonatization (dolomitization), and silicification, opal and chalcedony being especially abundantly formed.

(C) MINERAL DEPOSITS FORMED AT THE SURFACE BY HOT WATERS.

Mineral deposits may be formed at the very surface by hot springs, but they are then rarely of economic importance. A great number of minerals may result by direct deposition or by metasomatic action. All of the earthy carbonates contained in the water are here deposited at once, as sinter; the silica also as opal or chalcedony. The ordinary spring deposits thus consist of a mixture of carbonate and chalcedonic or hydrous silica. Calcite, fluorite, barite, celestite, and many other gangue minerals may also develop in crystallized form.

Of ore minerals stibnite, pyrite, marcasite, and cinnabar are known in crystallized form, and many other sulphides have been detected chemically in the deposits. Zeolites are sometimes observed as products of

rock alteration by mineral waters at the surface. Some sericitization of feldspathic rocks also takes place.

In most cases surface water containing atmospheric oxygen has acted on the sinters deposited at the surface or on the upper part of the veins. A complete change in the character of the deposits is effected by it. While under the influence of hot ascending waters practically no minerals rich in water form, and even zeolites are almost unknown, here, on the contrary, highly hydrated minerals are the rule. Limonite, and the whole series of hydrous oxides, carbonates, and sulphates of the heavy metals prevail among the ore minerals and kaolin, allophane and chloropal among the gangue minerals.

Kaolin has not been mentioned among the gangue minerals of any class of deposits except those formed or occurring under oxidizing influence, although the writer is well aware of the very general opinion to the contrary.

CONCLUSIONS.

The review given above indicates an almost unbroken series of deposits in which, in successively higher or cooler zones, the mineral combinations gradually change from those of pegmatitic and contact metamorphic conditions to those known to obtain at points where hot springs issue at the surface.

The contact metamorphic deposits have recently been connected with those of the lower vein-zones by the discovery that some of the latter contain silicates and other minerals supposed to be characteristic of the former. Under heavy pressure minerals of small molecular volume tend to form from solutions, and naturally this tendency would be most strongly indicated in those ore deposits which are contained in calcareous rocks. At the highest temperatures and pressures obtaining the solutions do not readily attack the feldspar and dark silicates of surrounding crystalline silicate rocks, although some of the *agents mineralisateurs* may penetrate them and deposit minerals like tourmaline and topaz. This seems to be the chief and not yet thoroughly understood difference between contact metamorphic deposits and even the lowest vein-zones in which the feldspars are unstable and are at once attacked under formation of various minerals. The ilmenite, spinel, amphibole, pyroxene, scapolite and biotite of the lowest vein-zones are missed in the upper zones in which sericitization and carbonatization prevail. The behavior of epidote is peculiar in that it is characteristic of the contact metamorphic deposits and the lowest vein-zones, while it is absent in middle depths, only to appear again in some veins near the surface.

The general character of the solutions as we know them from the deposits at middle and upper vein-zones is unquestionably alkaline, that is, they contained the alkaline carbonates as one of their principal constituents. There seems to be no evidence at all of the presence of such reagents as free sulphuric, hydrochloric, or hydrofluoric acid. At high temperature and pressure the behavior of the solutions changes in a marvelous degree, but in view of the scarcity of experimental data it is hardly profitable as yet to discuss their constitution and mode of action.

It is not to be assumed that the solutions which formed the mineral deposits always had the same general composition. Within certain limits they doubtless varied greatly. While there are numerous analogies which tie together the pegmatites and the cassiterite veins as both characteristic of acidic intrusion of normal granite, there seems to be no such evident connection between pegmatite dikes and gold-bearing veins. On the contrary, it appears that the intrusive granular and porphyritic rocks with which most of the auriferous veins are connected are remarkably deficient in pegmatitic dikes.

Production of Spelter.

The United States Geological Survey has issued a preliminary statement covering the production of lead in 1906. This has been prepared by J. M. Boutwell.

	1905.	1906.	Increase in 1906.	
			Quantity.	%
Production of spelter in the United States, tons	203,849	224,770	20,921	10.3

L. VOGELSTEIN & Co., New York, give the following figures of German consumption of foreign copper for the period January to June, 1907:

Imports of copper	Tons.
Exports of copper	59,637
Total consumption	1,130
As against a consumption during the same period in 1906	55,507
	61,115

Of this tonnage 45,776 tons were imported from the United States.

EXPERIENCED drill sharpeners often gauge the bits by the eye only, but it is advisable to make use of a gauge in sharpening the steel, as there is nothing more aggravating than trying to find a drill to follow one with a small bit. Many foremen are extremely careless in regard to the steel which they furnish to their miners, and the result is poor progress and dissatisfied employees.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

A mining lease provided for a certain royalty on the coal mined, and that the mining should commence within one year, but in the event that it did not, there should be paid as advance royalty for the first and second years a specified sum; and it was guaranteed that after the second year the royalty should amount to as much as a stated sum during the contract, or until all minable coal was removed. Where no coal was mined during the first two years, but the advance royalty was paid, it was held that such advance royalty should be applied on the royalties first actually earned thereafter, and the lessor was not entitled to have such royalties applied, if at all, only on the excess actually earned over the royalty guaranteed.

Kissick v. Bolton, (Iowa) 112 N. W. 95. (June, '07.)

Under a statute providing for the appropriation of lands for public use without the consent of the owner, and providing that the title should remain in the owner subject to the use for which it was taken, the owner of land taken for a right of way of a railroad, had the right to remove coal from under the right of way and to connect such coal by tunnels, but in so doing he must not impair the surface for the use of such right of way by removing the support.

Eldorado &c. R. Co. v. Sims (Ill.), 81 N. E. 782. (June, '07.)

The owner of a coal mine was held liable for injuries to a servant caused by an explosion of dynamite in the roof of the mine, placed and ignited by timbermen, whose duty it was to keep the mine roof in safe condition. And it was competent to prove the customary hours for firing shots by the timbermen in the entries of the mine, and that they were not usually shot at the time when the miner was injured, thereby showing that the injured miner exercised due care and that he had no reason to expect danger from such a source.

Donk Bros. Coal &c. Co. v. Thil (Ill.), 81 N. W. 857. (June, '07.)

A pumpman engaged at the bottom of a shaft in a mine, who knew that the shift-boss performed the duties of inspector, thereby assumed the risk of the inspection system under which the mine was worked.

Williams v. Verona Min. Co. (Mich.), 112 N. W. 496. (July, '07.)

A pumpman engaged at the bottom of a shaft in a mine was held to be a fellow-servant of the brakeman in charge of the hoisting cage, and that the mine-owner was not liable for the death of such pumpman by reason of the negligence or wrongful act of such brakeman.

Williams v. Verona Min. Co. (Mich.), 112 N. W. 496. (July, '07.)

The lessee of a mine obligated himself to pay the lessor a fixed royalty per month; but the payments were to be made to a certain bank and to be applied on the indebtedness of the lessor, which indebtedness was secured by a mortgage on the mining property. In an action by the lessor to recover the unpaid royalties, it was held that the defendant could not claim that the bank was a party in interest, and that the action should have been in its name.

Niekel v. Hodgens, (Mont.) 90 Pac. 757. (June, '07.)

A statute authorized liens on mines in favor of laborers and material men, but provided that it should not apply to the owner when the mine was worked by a lessee, if a copy of the lease was recorded in the mining records of the county before the work under the lease was begun. In the absence of a statutory definition of 'mining record' or of any designated record in which such instrument should be recorded, it was held sufficient to record such lease in a book kept by the County Clerk for the recording of leases and instruments effecting the title to mining claims, and which was designated 'mining conveyances.'

Slover v. Bailey, (Ore.) 90 Pac. 665. (June, '07.)

Gold Mining in Egypt.

Written for the MINING AND SCIENTIFIC PRESS
By C. S. HERZIG.

The romance of Egypt attracts the gold miner. Every old path winding over the hills he passes causes him to wonder how old it is; where did it lead to; who made it; and why? And to each of these old hill-paths he assigns a romance of gold worked in the distant ages before Christ. In the Bible, and in history, we read of the fabulous wealth of the ancient kings, and it is a common thing to hear people say that with our greater scientific attainments, and our modern methods, we should be able

General View of the Country.

to work mines that the old-timers were unable to touch. But that is a great fallacy, born of lack of knowledge, and the vanity of modern man! If we look back into the history of Egypt, we can trace at least three different epochs of mining in the country:

- 1st.—There was the epoch of the ancient Egyptian and Phenician living in Biblical times;
- 2nd.—That of the Roman, during his occupancy of the country;
- 3rd.—That of the Arabs and other Musselmen. (1

On the Road to the Nile Valley Mine.

have seen an inscription on the rocks at a mine I visited, dating back to the Mohammedan year 505, or 819 years ago.)

What the length of each period was, how many years or hundreds of years, it is impossible to state. One thing is certain, namely, that mining was carried on from the earliest times. There is an authentic history to that effect for fully 4,000 years. Gold was more sought after in ancient times than now, and before its discovery in California, less than sixty years ago, the world's production was only a small percentage of the present output.*

* For the 10 years preceding the California rush, the gold output of the world was only about 2 1/2 % of the present annual production, and prior to 1840 it was still less.

The farther back we go, the greater is the comparative value of the precious metal, and in the period of the Romans its purchasing power was probably a thousand times as great as it is today. This is the first important consideration affecting the probable value of ores worked by the ancients.

Before the invention of gunpowder the usual method employed for breaking ground was building a fire against the face; and therefore we usually jump to the conclusion that only very rich ore could stand the expense of such slow treatment. However, this is only one factor of the problem, for the mines were worked by slaves, the principal cost of whose maintenance was their food. Their clothing consisted of a little more than a breech-cloth, and that item could not have figured heavily in the total cost of maintenance. Moreover, the ancients' knowledge of mining and metallurgy, all things considered, does not suffer badly by comparison with our own.† They did not have recourse to the cyanide and other chemical processes, so widely applied at present; but, ages ago they practiced what is considered one of the greatest of recent advances in the treatment of gold ores, namely, fine-

Egyptian Grinding Mill.

Top stone on left; nether stone to the right.

grinding. They knew neither tube-mill nor Wheeler pan, but labor was cheap, and they accomplished the same result by grinding their ore between stones, usually of granite, and worked by manual labor, and then catching the gold on crude tables built of rock, 8 to 10 ft. long, about 3 ft. wide, and sloping sufficiently to let the water flow off freely.

At a mine I recently visited I took a sample of old tailing, and a screening test showed the following results:

Retained on 100 mesh	1.85 per cent.
Pass 100 mesh retained on 160 mesh	4.40 "
Pass 160 mesh retained on 200 mesh	5.75 "
Passed 200 mesh	88.00 "

From this it is evident that the sliming of gold ore has been accomplished in the earliest of times, and with oxidized ores the ancients must have recovered practically all the gold, except, perhaps, the very lightest particles, as nearly 94 % of the above corresponds to the present-day definition of 'slime.'

Whatever happened before or after, it is certain that the Romans brought great skill to bear in their prospecting and mining operations, for they were the teachers of the Spaniards, who in turn conquered and taught the

† The ancient Egyptians, as is well known, possessed the secret of tempering copper, now lost to us. Nothing but the old tailing remains as evidence of their knowledge of gold metallurgy.

Spanish-American and Mexican. And the Mexican is, in my opinion, the best prospector and ore-sorter on earth. And his teacher was, indirectly, the Roman, who, among other things, worked nearly all the copper mines at present known to exist in Spain. It is therefore likely that they roasted pyritic ores in order to free the contained gold, where this method was efficacious. The advances that have been made in modern times in the treatment of free-milling ores have been largely mechanical, although

ns, and we must inevitably draw the conclusion that the economic conditions existing now are so different to those prevailing in former times that the risk assumed in reopening an old mine is too great to warrant the capital required.

In Egypt, no virgin lodes of gold ore have been discovered within years, and if the mining industry is to have a future in the country, it will be due to the opening up of a mine whose existence has hitherto escaped the hordes of prospectors that scoured the country from the southern Sudan to northern Egypt long before the present European invasion.

The country is divided into concessions of large area, there being thousands of square miles in each. However, these large concessions are being canceled as rapidly as possible. The Government is framing new mining regulations, with the intention of throwing the country open to prospectors. But the difficulties to be encountered by men prospecting in Egypt are even greater than those existing in the desert country of Western Australia.

In Egypt, the country is not only a desert without water or fuel, without established means of communication, and without villages or towns where one can get fresh supplies; but the inhabitants of the country are

due credit must be given to the use of quicksilver and other chemicals used about a stamp-battery.

In ancient times the quantity of ore treated was small, as manual labor took the place of the modern power-plant. However, the miner could afford to do a large amount of dead work underground in order to find a pay-shoot, because when he did uncover one it repaid him for months of unremunerative labor. It is well to point out that this condition does not exist today.

It would be difficult to estimate the amount of money that has been expended by English and other foreign companies in endeavoring to find a mine in Egypt. However, the first profitable mine has yet to be discovered. Thousands of pounds sterling have been sunk, and a great many ancient workings reopened, all with negative results. This fact, and the points discussed above, lead me to the conclusion that the ancients were able profitably to work mines which, with all our scientific attainments, would not be payable at the present time. The biggest output of gold from recent workings was from a rich shoot found by the Nile Valley Co. But the total amounted to only about £100,000, which was put back into the mine, together with all the subscribed capital. One mine after the other is shutting down after an unsuccessful career, not one having paid a dividend, and of those still working the prospects are not too bright.

If we consider the gold romance of Egypt in this light, we shall not be ready to spend money in large sums on every ancient hole in the ground brought before

a colored race who do not speak our language, who have a religion which makes them antagonistic to the foreigner, and who—owing to the political condition of the country—are inclined to resent his presence. Again, the native considers that he is justified in swindling the

Loading the Caravan After the Noon-rest.

A Pile of Old Grinding Stones.

white man in every business transaction, especially if the white man does not speak the language well, or is not in the Government service. In other words, the only individuals who can expect anything like decent treatment from the natives, are the Government officials and the military. Even in the 'back blocks' of a country like Western Australia the amount of supplies which a prospector requires to carry is comparatively small, as he can pick up stores at fairly frequent intervals, and is always sure of a meal wherever there is a habitation. On the other hand, in Egypt, if a man starts prospecting in the desert he cannot get along with less than three

camels, and probably two natives. This means an expensive outfit in first cost, and a considerable expense in maintenance, as he must carry food for his camels, and food and water for himself and his Arabs. Therefore, it precludes the possibility of a prospector without financial backing undertaking any exploratory work. Then, if a mine be found, there are still all the drawbacks to the successful outcome of operations, due to the reasons stated above, namely, the lack of water, of fuel, of transport, and scarcity of labor.

The workmen are indentured on short terms, and the following is a form of a contract which was entered into by a company operating in the country, the terms being arranged by the Government Inspector of Mines:

CONTRACT

Between Mr. Blank, of the A. B. S. Mining Company, and the undermentioned workmen:

Mr. Blank agrees as follows:

1. To pay the following minimum rates, with a sliding scale for hammermen, making it possible for good workmen to earn up to 6½ piastres per day.

RATES OF PAY.

Hammermen.....	Minimum....	*5 P. T.
Laborer, underground.....	" ..	5 "
Laborer, surface.....	" ..	4 "

2. To provide men with rations and all traveling expenses, including camels for transport of their goods and water to the place of work.

On the completion of the contract he will provide the same means of returning. This will also apply to any man becoming incapable through no fault of his own, either by the act of God, illness or accidents, at the manager's discretion.

3. To pay monthly, not later than the eighth of each month.

4. To supply rations as or equal to the Government standard.

The men agree as follows:

1. To work for (4) four months from the date of arrival at the working place.

2. That any man proving incapable of doing a fair day's work as hammerman shall be put to work as laborer, either underground or at surface.

3. Each of the undersigned hereby acknowledges the receipt of 50 P. T. advance, to be deducted from his pay during the first two months equally.

RATIONS WEEKLY. — 14 lb. flour, 1½ lb. lentils, 1½ lb. rice, ½ lb. onions, with ¼ lb. each of salt and butter.

It will be noted that this contract is a one-sided affair. As the natives are independent, and the Government paternal, efficiency is not high, and the cost for the work that is done is great.

Without entering into a discussion as to the reasons or the statement, I feel that a mine, to pay in Egypt, will require to have a vein of good stoping size, and an average value of at least an ounce to the ton.

NICKEL IN CAST IRON.—In determining the effect of nickel on cast iron, 20 test bars, 10 with the nickel added and 10 without, all from the same ladle, holding 1,400 lb., and of good hot iron. Nickel thermite was put into the bottom of the hand ladles, the aim being to get varying proportions of the nickel into the metal and then to note the results of the tests. The results did not indicate a marked improvement in the physical strength of the castings, and bear out the supposition that nickel in cast iron is either not distributed uniformly enough to do much good, or else will find its best use in special classes of the metal free from the high percentages of impurities incident to the ordinary casting.

A Broad Apex.

A reader wants to know "if the apex law will hold on replacement deposits of copper in which the lime formation and included deposits along the bedding planes of the former dip at an average of 42°; or, if the side lines, continued vertically downward, limits the area of each claim, in which the ore may be followed on the dip."

If the United States mining laws were framed on the lines of obvious common sense, this inquiry might be answered categorically. But unfortunately, for the layman at least, some of the provisions of these laws are like those of the Medes and Persians—small characters written on high pillars. It requires a vast amount of climbing to read them intelligently and coherently and an inspirational gift to interpret them.

These laws were framed at an early period in the lode-mining history of the West. The conception of the miner at that time as to what constituted a 'lode' or 'vein' was simple and easily definable. The quartz veins of California, the supposed filling of a comparatively small fissure with gold-bearing quartz having well-defined walls, course, and dip, were undoubtedly the ideals on which the first mining law was framed, and upon the existence of which "the law of the apex" was predicated.

These ideal veins have proved to be the exceptions; irregularity of deposits is the rule. It may be said that in contemplation of the law, deposits in place carrying metals or mineral substances of commercial value are 'lodes' or 'veins.' That such lodes or veins have boundaries, strike, and dip; they also have an 'apex' upon the existence of which within the boundaries of a location the 'extra-lateral right' depends. It took many years of hard judicial effort to define what an 'apex' was. After the definition became fairly recognized, it was discovered that the top of the lode or vein was sometimes wider than the area allowed by law for side-line purposes, in fact wide enough to accommodate an indefinite number of locations. Then there came a time "when chaos umpire sits and by decision more embroils the fray." There were cases of "broad veins," bisected "apexes," and conflicting underground rights. The ingenuity of Court, counsel, and expert was taxed to solve the problems. Over in Colorado the tribunals started out with the view that unless a locator had the entire top of the deposit within the vertical boundaries of his claim he had no right of lateral pursuit. But Utah declined to follow this doctrine. Its Courts held that the location of any part of the apex of a broad lode carried with it the extra-lateral right and conflicting underground rights were to be settled by priority of location. In Leadville, where the deposits were replacements in approximately horizontal position with occasional exposures through erosion, the Courts held that the deposits were veins and necessarily had an apex somewhere. The unwritten "common law" of this district, however, as expounded by the juries of the vicinage, smothered the extra-lateral right and no extra-lateral right claimant in that part of the world ever succeeded in a lawsuit. The Utah rule has been sanctioned by the lower Federal tribunals. The Supreme Court of the United States has never passed upon the question. It has had several opportunities, but has thus far succeeded in avoiding a decision. The question is now before it in the case of *U. S. Mining Co. v. Lawson*, on appeal from the Supreme Court of Utah.

The difficulty comes from the necessity of treating the mining laws as a bed of Procrustes. There must of necessity be many misfits, and the "broad lode" is one of them. If we had our way about it, there would be no extra-lateral privileges attaching to zones or belts of mineralized rock, such as are described in the inquiry.

*A piastre is worth about 2½ pence or, say, 1½ cents.

The Uses of Copper.

The average man, if asked to name, offhand, the uses of copper, would be likely to reply that the metal was used mainly for coining pennies and making wire, yet

C. S. Herzig Aboard the Ship of the Desert.

these uses employ barely more than a quarter of the copper that is produced. On second thought he might smile at naming copper coinage as an important consumer of the metal, yet his first thought would be nearer right than his second, for the Chinese Empire has used 50,000 tons of copper for making new coins, within the past two years, thereby increasing the circulating medium of the country to the extent of four ounces for each inhabitant—for while 50,000 tons of copper is a large quantity of metal, sufficient to load 1,000 freight-cars of the heaviest type used on American railroads, it is but a quarter of an avoirdupois pound per capita, when divided between 100,000,000 people.

Only the expert, or those engaged most actively in the copper industry, have the slightest idea of the diversified uses to which copper is put, as shown in 'The Copper Handbook,' by Horace J. Stevens. According to this book copper enters into almost every form of human activity, and the multiplicity of its uses is most surprising. Electric light, power, and traction are immense consumers of the metal in the form of wire, and telephones and telegraphs find it indispensable, yet electricity requires only a trifle more than a quarter of the metal made. The engineering trades consume more than half of all the copper produced, mainly in the form of brass, but there are about a score of friction metals and alloys, each having its specific use, into which copper enters as a component part.

The building trades are enormous consumers of copper,

and this sort of consumption is increasing rapidly. Copper roofs, cornices, and fronts adorn the exteriors of business buildings in thousands of towns, while for interior work the great majority of modern buildings use copper, brass, or bronze locks, knobs, and butts. Brass pipes, nicked, are in modern bath-rooms and lavatories, and brass and bronze chandeliers, gas and electric fixtures are almost invariable. A dozen or more other very common domestic uses of copper are mentioned.

In the manufacturing world the uses of copper and brass are innumerable. One concern in the Naugatuck valley of Connecticut buys copper in ten-ton lots, monthly, solely for the making of watch-dials, all of the better-grade dials being of copper, enameled. The common pin requires hundreds of tons of copper yearly, insignificant as a single pin may seem. Bells for shoes and tips for shoe-laces require metal by the scores of tons, and the thin metallic tips on rubber-tipped lead-pencils are responsible for a surprising depletion in the stock of the metal.

In addition to the consumption of the metal itself, tens of thousands of tons of copper sulphate are required for the arts and manufactures, and for horticultural purposes, in spraying fruit trees, bushes, and vines.

USES OF QUICKSILVER.—The principal use of quicksilver is in the amalgamation of silver and gold ores. The demand for this purpose practically regulates the price of the metal. Considerable quantities are also used in the manufacture of a vermilion pigment, but this industry is suffering a decline occasioned by the competition of cheaper, but inferior red of the vermilion shade made with aniline dyes. In industrial chemistry quicksilver is used to quite an extent as an electrode in various processes. For example, in the manufacture of caustic soda a solution of common salt is subjected to electrolysis, and the metallic sodium set free combines with the mercury electrode, forming sodium amalgam, which when treated with water liberates sodium hydrate. Small quantities of quicksilver are used in medicine, as calomel or corrosive sublimate; as tin amalgam in the

West Australia and Egypt Side by Side.

manufacture of mirrors; for coating the zinc plates of electric batteries; as gold, copper, or zinc amalgams in dentistry; in thermometers, barometers, and various other scientific apparatus; and in electrical machinery where moving or liquid contacts are desired. A new use for the metal is in the mercury vapor electric lamp.

The Use and Care of Mercury.

Mercury is a metal that is liquid under ordinary temperatures and to this property it owes its other name, quicksilver, where quick means lively. The alloy of mercury with another metal constitutes an 'amalgam'; it is an alloy formed, in some cases, without the aid of extraneous heat, although in others the union is accompanied by evolution of heat and a modification of the mean properties of the components.

It often happens that mercury works unsatisfactorily in the battery or riffles. The following are some of the causes of the flouring and sickening of quicksilver, and various methods of remedying the evil.

Impure mercury is easy to recognize when trying to work with it, as it gives poor results. It may be recognized by shaking a small amount in a bottle, when a black film will form. If mercury is impure, when it is caused to roll down an inclined surface of glass or paper, it will do so in pear-shaped globules, having tails, and will leave a blackish film behind; it will leave a film on rough white blotting paper. If but $\frac{1}{1000}$ part of lead be present, a thin film will adhere to the glass plate. It is only pure mercury that forms an approximately true sphere.

Liquid mercury does not adhere to any substance except such metals as it readily amalgamates with. It 'wets' these metals, forming a thin adherent film on them, but when brought into contact with other substances, its surface tension comes into play and it forms spherules or takes a convex surface. Pure mercury is unaffected by air at ordinary temperatures, but will be slowly oxidized if it is heated to about 350° C. No commercial mercury is entirely pure, often containing traces of foreign metals, especially the more volatile ones, such as lead and zinc. Re-distillation will not effect a complete separation from them, as some part will always distill over with the mercury. To avoid this effect, some people recommend distilling at a low temperature in a current of superheated steam.

Although simple distillation will never completely remove impurities, a partial cleansing may be achieved in this way, and in this connection it is well to hint that care must be taken in distilling mercury as it is quite a different problem from retorting amalgam, and must be carried on slowly, and at a low temperature. When small quantities of lead or zinc are present, the mercury distills more slowly than when pure, although other metals do not seem to produce this result. One plan for producing the maximum cleansing effect by distillation is to collect the bulk of the distilled mercury in one vessel, and then, before applying the final heat, to divert the condenser-pipe into another vessel, keeping the last 10% separate from the rest, as it will carry most of the impurities.

Mercury forms an amalgam directly with gold, silver, copper, lead, bismuth, tin, and cadmium. It unites with antimony and arsenic only if heated. Iron amalgam is formed directly only if the iron is finely divided. Amalgams of nickel, cobalt, manganese, chromium, aluminum, and platinum are not formed directly, but may be formed indirectly by the electrolysis of their salts with mercury as their negative poles. Amalgams of sodium and potassium are formed directly with the application of a little heat. Since impure mercury will not act upon gold, even though the gold be in a perfect condition for amalgamation, it is important to use clean mercury in ordinary amalgamation processes, in order to reduce the losses as far as possible, although some millmen think that zinc or cadmium amalgams catch gold remarkably well.

Even though the gold and mercury be in perfect condi-

tion for amalgamation, and have amalgamated, excessive stamping, agitation, or grinding, may bring about the granulation of the amalgam and leave it in a condition to be readily floated away. When it is separated into these minute globules by mechanical causes it is said to be 'floured,' and if the particles cannot unite because of the coating of finely powdered substance, and this state of fine subdivision is thus made permanent, it is 'sickened.' In stamp-mills and grinding-pans the metal linings and crushing parts wear into minute particles that coat the mercury. Thus sickening may be due both to chemical and mechanical causes. The varnish on the battery screens may have a bad effect. Grease from bearings and candles must be avoided. For this reason plumbago and molasses has been used as a lubricant around the battery. Bad effects are sure to follow if exhaust steam is used direct to warm the battery-water, on account of the cylinder-oil. Organic impurities are deleterious. Vegetable or animal oils have a worse effect than mineral oils. Babbitt metal, lead carbonate, and even graphite may cause a sickening of the mercury in the battery. Trouble from grease may be remedied by the use of soda ash, lye, or burned lime in the mortar, and potassium cyanide is used to clean plates and promote amalgamation, as it removes oil, grease, and base metallic oxides.

There are many other causes for the sickening and flouring of quicksilver. Base metals associated with gold invariably coat the surface of the gold particles and prevent amalgamation. Native arsenic, copper, antimony, or bismuth reduce the value of the amalgam and interfere with the amalgamation. Arsenic and native sulphur make the mercury 'sick.' In the battery, the sulphide of antimony is one of the worst minerals to deal with, as it divides the mercury into a black flour, and this cannot be corrected by the use of sodium amalgam. Native antimony is not very injurious as it amalgamates readily, but causes a bulky clean-up. Tellurium is an enemy to amalgamation, and lead has a bad effect. The partial decomposition of some base minerals in refractory ores produces acidulated water, causing the mercury to granulate. An acid sulphate of iron arising from the decomposition of copper, or iron sulphides, or arsenical pyrite is injurious, but this is often corrected by the addition of quicklime to the battery.

All unctuous substances, as clay and talcose material in the ore, also the oxides of iron and manganese, promote the flouring and sickening effect, which appears to be the result of the physical presence of these substances, and not to a chemical action. Continuous stamping, agitation or grinding, causes mercury to form into minute globules that collect fine films of matter and air particles on their surfaces so as to prevent reunion of the globules, destroying the capacity of the mercury for amalgamation, and reducing the relative weight of the globules so that they are carried off by the water.

Potassium cyanide, sodium amalgam and other reducing agents tend to produce a reunion of the particles of floured mercury, possibly on account of the action of the nascent hydrogen on the mercury. An electric current may have the same result and muntz metal plates have been recommended because of a feeble galvanic action, electrolyzing the water, liberating hydrogen, and reducing the oxides that coat the mercury particles. It is accepted as a fact that in amalgamation on the plates or in the mortar or pan, free metals and dissolved salts are absorbed, and insoluble compounds of the heavy metals are reduced and amalgamated in part by galvanic action; in this action, the copper of the plates, or the iron of the mortar or pan constitutes the positive element, and all metals less oxidizable than this reacting metal are reduced by it and are then amalgamated by the mercury.

If lead is introduced into the amalgam the latter becomes pasty, and copper has an equally harmful effect.

Sodium amalgam has a strong reducing action and is used to rehabilitate sickened mercury, and keep it in good condition. It tends to reduce to the metallic form the oxides, sulphates, sulphides, and chlorides of base metals that coat the mercury globules, but this action causes the base metals to go into the quicksilver and may do more harm than good. For this reason the use of sodium amalgam is not generally recommended; for while the mercury is made bright again and the finely divided particles are able to coalesce and amalgamate gold freely, still there is no permanent purifying action, since the base metals have merely passed into the mercury and are soon oxidized again, when the process must be repeated. Sodium amalgam is made by heating a vessel of mercury to 300° F. and dropping in pieces of metallic sodium not larger than a pea. When these pieces touch the mercury there is a slight explosion and a bright flash of flame, until about 3% of sodium has been added, when the action becomes less pronounced. Then the amalgam is poured on a plate to cool and solidify, and when hard is broken into pieces and kept in a bottle under naphtha. If it is used in the battery, the procedure is generally to add it in such amounts that the mercury will adhere slightly to the brightened edge of a nail. If it coats the nail all over, too much sodium has been added and more mercury will have to be fed in, or if it does not adhere at all to the nail where it has been filed bright, more sodium amalgam may be used. While it is considered to have apparently little value when fed into the mortar in this way, still it is used in amalgamating pans, or in rittles, or mercury wells, or in cleaning retorted mercury, or wherever it can act directly on a considerable amount of mercury. Electric currents and galvanic couples have a reducing effect similar to sodium amalgam.

If it seems best to attempt the purification of foul mercury by distillation, choice may be made of several methods. It may be distilled in a capacious retort, like a cinnabar retort, under a layer of cinnabar. The sulphur of the cinnabar combines with the foreign metals and prevents their passing over with the distilled mercury. Or it may be retorted similarly under a layer of quicklime or iron filings. In this case the iron filings prevent bumping and splashing and decompose the sulphides, and all the arsenic or sulphur liberated is absorbed. The retort should never be more than half-full of mercury and the distillation should proceed slowly. Charcoal may be added in the retort to prevent the volatile oxides from passing over. At best, some lead and zinc will probably go over with the mercury.

It is generally better to employ a chemical method of purification. Small quantities of mercury can be partially cleansed by vigorous shaking in a bottle not more than one-quarter full, with some crushed granulated sugar, subsequently filtering through a cone of heavy blotting paper with a small hole at the apex. This method of filtration is useful in removing any suspended impurities. Small quantities of impurities such as lead may be removed from mercury by keeping it for some hours in a vessel under dilute nitric acid, occasionally stirring the mass. This acid dissolves the lead and copper, and some mercury, but the mercury is precipitated again when a fresh charge containing lead or copper is treated with the acid. The last of this dissolved mercury may be recovered by adding a piece of metallic copper to the solution. Pure mercury is not attacked by hydrochloric acid, and only slightly by dilute sulphuric, but it is acted upon by hot concentrated sulphuric acid or by cold dilute nitric acid, and is rapidly dissolved by hot nitric acid. Therefore, zinc, tin, copper, and iron may

be removed by shaking the mercury with dilute hydrochloric acid. In fact, if mercury is placed in a vessel and allowed to stand for some time under a 1 to 3 dilute solution of hydrochloric acid, it will be gradually purified, especially if stirred occasionally. Small amounts of impurities can be eliminated by treatment in this way with potassium cyanide, caustic potash, or dilute acids. The purified mercury is best kept in an earthenware, glass, or porcelain vessel, under a layer of weak potassium cyanide or nitric acid, the quicksilver being drawn off when needed, from the bottom, through a stop-cock, and washed in water before using. Acidulated water may be added to the vessel if the nitrate of mercury encrusts the surface. The elimination of the base metals may be hastened by passing a stream of air through the mercury under this acid cover, as the foreign metals are oxidized by the air and dissolved by the acid. A cleansing method that has been recommended is to wash the mercury in a bath made by dissolving one tablespoonful of potassium cyanide and two tablespoonsful of ferrous sulphate in a gallon of water. An efficient method for removing zinc and tin is to let the quicksilver trickle in a fine spray down a 3 or 4-ft. column of ferric chloride solution. Agitation with strong sulphuric acid and potassium chlorate has been successfully used; digestion with ferric chloride removes the zinc and tin, and heating with a solution of mercuric nitrate will dissolve the foreign metals as nitrates, the mercury being precipitated. If greasy or resinous impurities are present, some operators wash the mercury in a strong solution of alkali, made from wood ashes.

STEEL PASSENGER CARS.—The development of all-steel passenger cars has been much slower than steel freight cars. This was probably due to the fact that steel freight cars were required to carry a greater load and not increase the dead weight, a little experience having taught that 40 tons or over was too great a continual loading for a wooden car. In passenger car construction the question is different. It is true that present passenger coaches are somewhat longer and much heavier, and will resist impacts that would have wrecked cars built 10 years ago. But they are operated at higher speeds, so the average passenger coach today is relatively no stronger than the old-fashioned cars. For high-speed service it is practically essential to use a steel car, if the safety of the passengers is considered. The force of impact in a collision will splinter the sills, posts, and side plates, and a passenger caught in the wreckage of a wooden car has not much chance, particularly with the addition of a fire. Aside from the question of accidents, steel passenger cars should be a good investment, as the running repairs are less, the car being out of service a shorter time when going through the renovating process, and the steel surface is easier to finish than the wood and does not require so much care, and, with steel freight car experience as a guide, the life will be much longer.

MINING IN FORMOSA.—The principal coal mines of Formosa are situated in the Keelung district. The output for that district for the first six months of 1906 was 29,643 tons, valued at £9,820. Copper ore has been discovered at the Kinkwaseki gold mines, Keelung district, and work has been commenced on it. There are at present 21 coal mines. The majority are merely tunnels run into the side of the mountains, and there are only two or three which produce coal of good quality. The Henryoko coal mine, which is said to be the best, produced 8,271 tons in 1905, the total output in the island for that year being estimated at only about 81,000 tons.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

ORE-SEPARATOR.—No. 853,782; Lon D. Hall and Samuel P. Hall, Prescott, Arizona.

An ore separator comprising a main frame, an endless movable apron mounted in the frame and composed of reticulated material, the relatively lower portion of the apron traveling in a plane below the upper edge of the frame, a receptacle frame supported at one side of the main frame and disposed between the upper and lower portions of the apron, a receptacle supported by said frame and arranged transversely of the path of travel of and between the upper and lower portions of the apron, a discharge pipe leading from the receptacle and supported in one side of the main frame, a second receptacle supported from and lying wholly beneath the main frame, said receptacle extending in the plane parallel to the path of travel of the apron and projecting at the ends beyond the operative plane of the apron, a discharge pipe communicating with the second receptacle, and a spraying device overlying the lower portion.

ORE WASHER OR CONCENTRATOR.—No. 859,354; Enos A. Wall, Salt Lake City, Utah.

An ore washer or concentrator comprising a horizontally disposed tubular body, having its head end extended upwardly above the top of the body to give the proper head to the water and ore fed therein, and having its opposite or tail end closed and provided with an outlet for the waste material and water at its upper portion above the level of the upper internal surface of the body; whereby the tubular body is maintained completely filled with water, and air contact with the contents avoided, and means for imparting a longitudinal reciprocating movement to the tubular body adapted to cause the concentrate to move toward the tail end of the body.

ORE OR SAND CONCENTRATOR.—No. 861,787; Frederick A. Wiswell, Salt Lake City, Utah, assignor to Wiswell Milling Machinery & Mining Co., Salt Lake City, Utah.

In a device for separating materials, the combination of a tank adapted to contain water, a longitudinally inclined perforated table therein, an endless apron traversing said table, sufficiently wide to cover the perforations thereof, and means for intermittently pulsating water in said tank.

ONE-STAMP MILL MORTAR.—No. 862,298; George H. Nissen, Toronto, Ontario, Canada, assignor, by mesne assignments, to The Nissen Engineering Co., a Corporation of Arizona.

In an ore stamp-mill mortar, the combination of a body having an inlet for ore, an outlet for the pulverized ore, a recess within which the ore is pulverized and an outwardly and upwardly flared portion extending from the upper part of the recess to the level of the discharge opening, an annular amalgamating plate on said flared portion substantially covering the same, protecting plates covering said amalgamating plate and detachably connected thereto, and a die in said recess.

PROCESS OF SEPARATING ORE.—No. 861,782; Henry H. Wait, Chicago, Ill., assignor to International Separator Co., Chicago, Ill., a Corporation of New Jersey.

The herein described process of separating ores having different degrees of porosity from a mixture, which consists in impregnating the mixture with a solution of an iron salt, subjecting the same to an oxidizing agency to form a magnetically permeable oxide upon the more porous material, whereby its particles are rendered susceptible of magnetic attraction, and then passing the mixture through a magnetic separator to remove the particles which are thus artificially rendered susceptible.

SLIMES TREATMENT.—No. 860,775; Charles E. D. Usher, Jeppestown, Johannesburg, Transvaal.

Apparatus for the wet treatment of metalliferous slime, consisting of a vat, means for maintaining the slime therein in a substantially uniform state of suspension, and means for passing a liquid from the bottom of the vat upwardly through the contained slime, means for continuously drawing off clear liquid from above the slime, and means for returning the liquid for further percolation through the slime.

Quarry Work.

During the past fifteen years great progress has been made in quarrying methods, chiefly in installing equipments of machinery to replace the old fashioned and laborious hand-work. Broadly speaking, quarrymen have not readily taken advantage of the benefits to be derived from the use

Chicago Giant Rock-Drill.

of machines designed and adapted to their every-day work. Rather, as a rule, they have been conserved to old methods until driven by competition or the necessity of increasing their production they have been in a sense forced into looking for machine tools to help them out of their dilemma, and even when at that stage, it took many and long hard arguments to induce them to make a trial. But times have changed, so that nowadays it will amply repay anyone sufficiently interested to visit and inspect the power plants at the large quarries in the Ohio sandstone field, the marble quarries of Vermont, or the granite quarries of the East, where one central system is made to supply power for all the machinery used in quarrying and moving the material. Naturally, it was the owners of the large quarries who first made the change; as to the owner of a small quarry the first cost of a machine tool equipment seemed a serious matter, but one after another they keep falling in line, till now, should a prospective investor be in doubt as to the advisability of installing machine tools, it is only necessary for him to visit the nearest similar quarry to his own where they are using machines and let his neighbor tell the story.

After deciding to put in machine-drills, the next question is whether to put in a steam or air plant to operate them. This question is usually answered by a study of the local conditions and whether there will be other machines to

operate, such as hoisters, derricks, and pumps; also whether hand machine-drills are to be used. When the advantages to be gained outweigh the first cost, a central air-power plant is the most desirable installation; but when only one or two machine-drills are to be used and there is no objection to the use of steam, a steam-power drill outfit will be the simplest, also least expensive and providing the proper type of drill is selected the performance will be about equal to that accomplished by the air-power drill.

The accompanying illustration shows a Chicago Giant rock-drill operated by steam, at work on a quarry at Twinsburg, Ohio. This type of drill gives best results when operated by air, but it will also give better satisfaction when operated by steam than any other type of rock-drill on the market. This drill is manufactured by the Chicago Pneumatic Tool Co., 1,010 Fisher Bldg., Chicago.

The Goodman Locomotive.

The two-motor type of mine locomotive does not lend itself well to adaptation for successful gathering service where cars must be handled to and from the face. It cannot ordinarily be built in form sufficiently compact to fulfill properly the requirements of this work. For narrow gauges such a locomotive must have frames outside the wheels, and the over-all length is necessarily excessive because of the construction required for accommodating the two motors. Furthermore, the wheels in a two-motor locomotive must be large, and this prevents running satisfactorily around sharp curves.

Other matters, including length of wheel-base, general over-all dimensions, lack of flexibility in the truck, etc., combine to prevent successful adaptation of a standard two-motor haulage locomotive to the special work of face gathering. For this service, therefore, the Goodman Manufacturing Co., of Chicago, has brought out a line of special gathering locomotives, their design involving all the essentials of compact construction, small wheels, short wheel-base, flexible truck, single-motor drive for the four wheels, and utmost accessibility to all parts. These special single-motor gathering locomotives are built in three sizes, designated as Types 1600, 2600, and 3200. All three include the same general principles of construction, and are particularly designed for quick handling, as of importance in gathering. The illustration shows the Type 2600. The

The Goodman Locomotive.

1600 is lighter and the 3200 is heavier. Type 1600 stands only 32 in. high above the rails, and is only 93 in. long. Types 2600 and 3200 are 35½ in. high and 9 ft. long over the bumpers.

By reason of the short wheel base and small wheels, any one of these locomotives will go wherever a mine-car of

equal dimensions can be run, and, having a flexible truck, will follow a rough or poorly laid track even better than will the mine-car itself. Through gearing of special design and arrangement the armature of the single motor is in positive driving connection with both axles, yet without interfering with the flexibility of wheel-base.

The United States Smelting, Refining & Mining Company.

It will be a matter of very great interest to our readers to know that the United States Smelting, Refining & Mining Co., a Maine corporation, with its executive offices at Boston, has secured such a footing in the field of custom smelting that mine operators in America are no longer dependent upon the Guggenheims or so-called smelter trust. The United States Co. claims to treat a greater tonnage west of the Rockies than the Guggenheims, and within the past year this company has invaded Mexico. The Bingham Junction or West Jordan (Utah) copper and lead smelter of the company, while originally built to handle the product of the company's own mines in the Bingham and Tintic districts, have recently been doubled in capacity, and the plant now ranks as one of the most modern of the large custom smelters of the world. It is situated in the Salt Lake valley, but a dozen miles from Salt Lake City, and is reducing daily an average of 2,500 tons of ore, which comes to it not only from Utah, but from mines and matte furnaces in Colorado, Montana, Idaho, Nevada, and California. The company also owns at Kennett, in Shasta county, California (operating under the title of the Mammoth Copper Co.), six copper blast-furnaces and a new converting plant. It is now building a tramway to these copper mines, but the Kennett smelter is at the same time a custom plant, treating the ores of Tonopah and Goldfield, as well as those of California, Oregon, Washington, and Idaho. At Eureka, Nevada, the Richmond-Eureka Mining Co. is another subsidiary. At this place new hoisting machinery is being installed, and pumps placed for taking out the water that stopped the mines in the early days. At Eureka the old dumps of the several mines contain sufficient ore to justify smelter construction, so that further construction is expected of the company in Nevada. Now and then zinc ores are found that cannot be economically treated in an ordinary smelter, so the company is allied with the American Zinc, Lead & Smelting Co., with mines in the Joplin district, and zinc smelters at Caney and Deering, Kansas, to treat zinc ores, no matter where they originate. These zinc plants have already been found inadequate to the needs of the growing business of this progressive corporation, and material is now being secured to double the present capacity of the plants at both places. In order to be able to treat its own product, as well as to refine the copper and lead of other independent smelters, the United States Co. has recently erected at Grasselli (East Chicago), Indiana, an electrolytic lead refinery with a capacity of 3,000 tons monthly. At Chrome, N. J., it owns and operates (under the title of the United States Metals Refining Co.), an electrolytic copper refinery of 12,000,000 lb. monthly capacity, as well as a copper smelter and converting plant treating the ores of Canada, Nova Scotia, Vermont, the Southern States, as also matte and bullion from Mexico, South America, and Japan. A large dock has been built at Chrome, so that the smelter can receive both by rail and by water.

In Mexico the United States Co. is the holding company for the rich Real del Monte mines and mills at Pachuca and Real del Monte, in the State of Hidalgo. Here the mines have been equipped with electric hoists in 18 well developed mines, and two new mills have been constructed on the property, which consists of 173 claims, and covers 20 miles of territory. A custom smelter is now being planned, and will shortly be erected by the company in Mexico at a point not yet announced; but as ore contracts are being taken, it is safe to assume that the plans have been matured, and that the erection of the smelter will soon be commenced. At Rio Blanco, in the Peruvian Andes,

the company controls the Churruca copper mines and smelters, operating under the name of the Peruvian Mining, Smelting & Refining Co., with head offices at Lima.

The American Exploration Co., with its large staff of mining engineers constantly in the field, and the International Metals Selling Co., which is the selling agency for its products in America and Europe, are two of the subsidiary organizations. The United States Smelting, Refining & Mining Co. occupies an enviable position in the mining world especially, as throughout the inter-mountain district it has been the means of reducing treatment charges, and compelling respect of friend and foe alike. It is an energetic and shrewd organization of experienced mining and metallurgical men, with a financial rating that is of the strongest. Its capital is \$75,000,000, of which \$41,000,000 only is issued, and on which annual dividends are paid at the rate of seven per cent. William G. Sharp and W. H. Coolidge, of Boston, are president and vice-president; Albert F. Holden, an acknowledged leader in the mining and metallurgical field, is the managing director. On the board of directors are many of the richest and most influential men of New England.

Commercial Paragraphs.

T. B. BURNITE, of the engineering and sales department of the John A. Traylor Machinery Co., Denver, has been appointed superintendent.

THE WESTERN ENGINEERING & CONSTRUCTION COMPANY no longer represents the Bucyrus company, that arrangement having expired by limitation. Therefore, the engineering company mentioned is at liberty to construct dredges and placer machinery of every kind.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING Co. of East Pittsburg, has received through G. & O. Branliff & Co., agents for the former company in Mexico, an order for one of the electrical equipments of the Vera Cruz tramways, built by the Vera Cruz Light, Power & Tramway Co. Vera Cruz is the second city in Mexico to be electrified.

THE FOUNDATION COMPANY, of New York, has just been awarded the contract for sinking a mine shaft on the Swanzy range, near Ishpeming, Mich. The size of this shaft will be 21 by 17 ft., and it will be sunk through about 70 ft. of water-bearing material. The Foundation Co. has also been awarded the contract for the foundations of the new 16-story office building to be erected at 160-164 Broadway. This building is for the Lawyers' Title, Insurance & Trust Company.

THE COLORADO IRON WORKS COMPANY reports a large business in smelting equipment during the past few months, the orders coming from all quarters. While the bulk of this business is from the United States and Mexico, other foreign countries have been represented and orders for either furnaces or complete plants are going through the shops for installation in France, Japan, Chile, and New Zealand. The furnace included in the Chilean plant is designed for hot-blast smelting, and the New Zealand order embraces the complete equipment of a hot-blast copper-matting plant with a sampler.

Catalogues Received.

THE PACIFIC TANK Co., of San Francisco and Los Angeles, is sending out Catalogue No. 6, on 'Cyanide Tanks.' It contains 192 pages, and describes tanks and mill supplies.

THE FRED M. PRESCOTT STEAM PUMP Co., of Milwaukee, has published an exceptionally attractive catalogue on 'Prescott Pumping Machinery.' It is profusely illustrated, well printed on excellent paper, and contains much useful information.

Publications Received.

'The Progress of the Mineral Industry of Tasmania,' for the quarter ending March 31, 1907. W. H. Twelvetees, Government Geologist.

Editorial.

CHANGE-ROOMS are both useful and sanitary. The objection to them can only be grounded on the wish to permit the stealing of ore to go unhindered. If a strike follows upon the building of change-rooms at the Mohawk and Combination mines, we hope the managers will not yield to the clamor of those who want to perpetuate sneak thieving at Goldfield. The stealing of ore is bad enough as an abuse of property rights, but it is even worse as a practice that corrupts the mining community and maintains a gang of fictitious assayers, together with other receivers of stolen goods.

GENERAL BOTHA and the legislature of the Transvaal have decided to purchase the Cullinan diamond and present it to King Edward, in token of their appreciation of England's magnanimity. The Cullinan diamond was found in the Premier mine, near Pretoria, on January 26, 1901. It weighs 3,032 carats or 1.7 pounds Troy. The dimensions are 1½ by 2½ by 1 inches, so that it is obvious the stone is of extraordinary dimensions; the largest ever found previously was the Jagersfontein, which weighed only 971 carats. The Cullinan is colorless, perfectly transparent, and the purest of all the big stones. Mineralogists have ascertained, from the appearance of its cleavage planes, that this stone is a part of a much larger one; four pieces have been broken off in the course of geological movement to the place where it was found, and the original form of this piece of crystal-line carbon can only be guessed. The gift of it to the English king is a graceful act and the spirit of it expresses a gratitude finer than a gem of many carats.

SPECULATORS IN STOCKS have been uneasy of late and there are signs that the bankers and brokers of New York have had an attack of the nerves. The prosecution of the Standard Oil, the ominous language of the Attorney General, the uncertainty as to which corporation is next to be attacked have frightened the financial groups whose activity keeps the stock market buoyant. "Too much Roosevelt," says one banker. "Corporation baiting," says another. "Attack on railroads," growls a third. All of which may be measurably true. It might be better for the chief law officer of the Government not to joke about "the poor old Standard", it might be more dignified of the President not to berate Mr. Harriman, it might even be safer for the Administration to be on friendly terms with Wall Street, but on the whole we do not accept these as the causes of precipitate liquidation. What we have been seeing of late is a coincidence rather than a consequence. There is acute financial depression at London, there is industrial gloom in continental Europe, there is a collapse in the value of shares at Johannesburg; is that due to Mr. Roosevelt

and Mr. Bonaparte? Hardly. The fact is the market has been through a time of great speculative expansion, the water that was turned into golden wine by the transmuting wand of the promoter turns out to be a feeble liquid, by the natural operation of economic laws the water is being squeezed out of the stock market, and it feels feeble. It is so at Johannesburg, Alexandria, Berlin, London, New York. A local event starts a local manifestation of a worldwide condition. After excessive speculation comes liquidation; after unrestrained prosperity comes depression; after a period of excessively high wages come strikes. It is an old story, told with weary iteration at regular intervals.

Indexes.

THESE may not suggest the most thrilling kind of literature, but they represent one of the most useful forms of book-making. On another page we publish an article by Dr. R. W. Raymond describing the consolidated index to be published by the American Institute of Mining Engineers. With his customary skill he has made a keenly interesting article out of an apparently uninviting subject. Several good suggestions are offered; one of them we venture to emphasize, and that is a conscientious reference to previous contributions on the same subject. While intended to apply primarily to the Transactions of the Institute, it may well be taken to heart by all who write on technical subjects. Even a reference to a contemporary is in good taste in a periodical journal and the recognition of previous writings on the same subject is, to say the least, a scholarly act.

While speaking of indexes, there is one point worthy of note, namely, the choice of a title for a book or an article. Manifestly the shorter the article the longer its title, for as it refers to a small part of a wide field of knowledge the particular scope of it must be indicated. And as it happens that some of the short articles are worth as much as some big books, it is to be regretted that they are found with difficulty in indexes because their titles are not correctly expressive. We have noted this fact in using the Engineering Index published by *The Engineering Magazine*. It is the best general index relating to technical matters, but the usefulness of it has been lessened in many instances by the unintentional perversity of authors who have chosen inappropriate titles. 'Cyanidation in the Transvaal,' for example, is a perfect title because, while brief, it names the process described and the locality where a given method is practised. You can easily find such an article either under 'cyanidation' or under 'Transvaal,' which are the two ideas first associated with the article, the third being the author's name. 'Three Weeks in Mexico' is a badly chosen title because it expresses so little; the only valuable member is 'Mexico,' indicating locality. The 'three weeks' mean nothing. It is impossible to tell what subject is discussed in such an article; obviously, it cannot be the passage of time in Mexico. 'Some Notes on the Occurrence of Copper Ore in Arizona' is another common form of mistaken nomenclature. 'Some' is with-

out value; 'notes' is not much better; the two dominant ideas are 'copper' and 'Arizona'; they ought to be brought out clearly. 'Copper Ore in Arizona' would be an improvement. Another nuisance in indexing is the constant employment of the definite article 'The.' Of course, 'The Geology of Jamaica' may be prettier than 'Geology of Jamaica' but not much, not enough to balance the trouble given to the hardworking individual that prepares a useful guide to current literature and the earnest student digging for data. Much the same may be said of prefixing the indefinite article, as in 'A New Method of Pyrite Smelting'. The article can be spared with advantage. Titles should be as indicative as possible; that is their first function.

Zinc Corporation.

RARELY has the proverbial pluck of British shareholders been better proved than at the recent meeting of the Zinc Corporation, when a frank explanation of ill success was met by a resolution to try again. It will be remembered that this company was organized to buy and to treat dumps of tailing at Broken Hill, it being confidently expected that recent acid flotation processes would permit of the profitable extraction of zinc, silver, and lead in the tailing discharged from the concentrating mills on the Barrier range. The story has had three chapters headed by three processes that have been successively tried and discarded. First the Potter process was adopted and rejected; then the Queneau modification of it, under the inventor's direction; then the Cattermole, which, however, is now giving profitable returns in the hands of the Sulphide Corporation. Not one of these three has proved "a commercial success." Now the Elmore process has been chosen as the most effective variation of the five or six that use an admixture of oil and acid to float the particles of zinc. This is an incident in the big battle of the processes at Broken Hill. Some of the contest between the rival inventions has been fought in the Australian courts; further litigation is under way in London. It is known that a test case will be made as between the patent rights of the Cattermole and Elmore processes; therefore the choice of the latter in the crucial stage of the Zinc Corporation's existence indicates some confidence in the outcome of the litigation between the patentees. At the meeting mentioned, the chairman, Mr. F. A. Govett, spoke of the fundamental similarity between the various processes that they had tried, and stated that the essential variation began after the selection of chemicals, the difference consisting in the mechanism employed to float the particles of mineral and the devices used to trap them after they have been floated. It was announced that in three trials on a working scale, the Elmore process had given 83 to 89 per cent extraction with a 44 to 45 per cent zinc concentrate. Furthermore, the Elmore does not require as fine grinding as the other methods, and it is claimed to work with solutions at the normal temperature instead of requiring heat. In supplementing the chairman's speech, Mr. H. C. Hoover, the responsible engineer,

referred to the Elmore process as apparently "the solution of the difficulty," adding that he could offer no guarantee, for "a responsible engineer never guarantees anything." Which is a true word, said at a trying moment and with rare courage. The Zinc Corporation has available nearly 4,000,000 tons of tailing, so that success in treatment will represent a handsome profit. Even if the new departure ends in disappointment, the episode is worth the price of a heap of tailing, for the pluck of the shareholders, the manliness of the chairman, and the professional integrity of the engineer unite to form an episode pleasant to chronicle in this journal.

Lawlessness and Romance.

IF SOME of the endowments now devoted to universities could be diverted to the maintenance of a few wholesome daily newspapers, the education of the community would be furthered. There are plenty of good technical and professional periodicals, besides the monthly magazines, but the printed matter given to the public every morning and evening is, in San Francisco, for example, so inaccurate and inept, when not purposely misleading and mischievous, that a constant process of civic corruption and mental degradation is at work. More people read newspapers than hear lectures; the student is compelled to correct his lecture notes by reference to books; a large portion of the community reads the newspapers without correction from books; if any books are read, they represent the fiction that amuses, not informs. In short, the average citizen is at the mercy of a press that is a by-word for inaccuracy and the average home is polluted by daily rubbish masquerading as literature. This may not be politic, but it is true. There are a few clean and forceful newspapers, and they can be easily counted. Among them is *The Evening Post*, of New York, which stands for what is safe and sane in journalism. Having a great respect for the *Post*, we have read with regret one or two articles on the new goldfields of Nevada in which the old notion of frontier lawlessness and picturesque disorder is made the keynote to a portrayal of life at Tonopah and Goldfield. In a recent issue there is a highly colored account of the trouble between the labor unions and the mine operators. Such men as George Wingfield, Jack Davis, and Tom Kendall are portrayed as heroic gun-fighters of the type ennobled by Bret Harte; and L. C. Branson, the editor of the *Tonopah Sun*, is pictured as an audacious fire-eater worthy of Marryat's novels. This is all out of focus. We in the West are no longer on the frontier, that frontier has gone with "the path of empire," westward, to the Philippines. Lawlessness is as much lawlessness in California or Nevada as it is in New York or New Jersey, and no efforts of an Eastern *litterateur* can make it anything else. If the Industrial Workers of the World and other leaders of an unintelligent tyranny at Goldfield try to bulldoze a respectable community, it is silly to set up a braggart gun-play in opposition. A community devoted to industrial pursuits such as gold mining ought to look to its police, its Sheriff, and its District Attorney to protect it

and not depend upon a group of gamblers and saloon-keepers, with more than common nerve and an unusual touch on the trigger.

We shall be informed that the constituted authorities were not reliable, or were openly on the side of disorder. The Sheriff was supposed to be controlled by the belligerent labor union and his deputies were members of that organization. This is an old story, unfortunately also true in the *Coeur d'Alene* and in the San Juan during troublous times, but the permanent cure for such ills is to be found only in returning to first principles; popular government by popular vote chose the men false to their trust and the popular vote must select better men to replace them, as soon as the community realizes the blunder that has been made. Create a healthy public opinion and the rest is easy. In Nevada public opinion was terrorized by both sides. We are informed that Jack Davis has been seen marching about with five pistols attached to his belt; he would go to a restaurant and thump them down, two on each side of his plate, the odd one remaining on his person, much to the edification of small boys and tourists. In a similar spirit of braggadocio the editor of the *Sun* would publish in flaring headlines the invitation to the "dirty scoundrels" to "start something," and he would print in big type across the seven columns of his paper such epithets as "Cowardly Curs" and "Sneaking Dogs." This is sophomoric foolishness. It is no province of decent journalism to invite even the worst ruffians to a gun fight, and it is bad citizenship to foment riot. The story is told of Jack Davis getting an idea that the labor-union people had bought all the guns and ammunition in Goldfield, so he rushed off in an automobile, with a friend in another machine, to Tonopah, and begged the operators there to join him in buying all the ammunition in that town. *The Evening Post* calls it 'Reform in the deserts of Nevada' and while we are not wholly dense to a touch of humor, it is obvious that the incidents related are disgraceful rather than funny. It may afford copy to a light-hearted scribbler, but it is a palpable break-down of popular government and a state of anarchy discreditable to any self-respecting community. Fifty years ago there was some excuse for protecting the community by the guns of saloon-keepers and gamblers; this was before the State was properly organized and before the regular administration of law was practicable; but we have gone far beyond those beginnings of civilization and the cowardly six-shooter, except in necessary self-defense, is as out of date as the vigilance committee and the pony express. Lawlessness is not romance, and "getting the drop on a man" is not heroic. This notion of curing social disorder with more of the same kind, of stopping the brutality of one mob by applauding the brutality of another, is not justice, or law, or civilization. At Boisé, in San Francisco, at Goldfield, we see manifestations of the same tendency to take sides and to make a vendetta out of a situation that ought to resolve itself simply into the assertion of the law, supported by all good citizens, and the administration of an impersonal justice, superior to all partisanship.

Personal.

R. H. CHAPMAN is at Karlsbad.
A. J. McMILLAN is at Rossland.
FRANK H. PROBERT is in Sweden.
THOS. H. LEGGETT is at New York.
E. McCORMICK is at Metcalf, Arizona.
W. MURDOCH WILEY is at Guanajuato.
KARL EILERS is here from New York.
W. C. BRACE, of Denver, is at New York.
W. R. RUST and EDGAR NEWHOUSE are here.
G. F. BEARDSLEY was in San Francisco this week.
A. C. HEWITT has returned to Denver from New York.
W. FISCHER WILKINSON, of London, is on a visit to New York.
A. W. GEIST has returned to Guadalajara from New York.
O. H. FAIRCHILD is examining mines in Gilpin county, Colorado.
THOMAS RICKARD has left London to visit copper mines in Norway.
G. BURROWES is on his way from Vancouver to his home in England.
C. M. FUELLER, of Denver, is doing professional work near Marysville, Utah.
L. W. GETCHELL, of Boston, is examining the Cinco Minas in Jalisco, Mexico.
IVAN E. GOODNER is contracting engineer and surveyor at Rapid City, South Dakota.
H. W. HARDINGE, on his return to New York from the West, has gone again to Cobalt.
EDWARD S. WIARD, of Denver, is doing professional work at Animas Forks, Colorado.
C. P. BOWKER is manager of the Aguila mines in the Hostotipaquillo district of Jalisco.
PHILIP WISEMAN is general manager for the Consolidated Copper Co. at Kelvin, Arizona.
THEODORE GROSS is at Mexico City, as head of the Mexican Mining & Industrial Corporation, of London.
ALBERT BURCH has returned to San Francisco from Mexico. His office is now in the Crocker building, as before the fire.
JESSE SCOBEEY is at the mines of the Virginia & Mexico Mine & Smelter Corporation in the Hostotipaquillo district of Jalisco, Mexico.
LOYAL W. TRUMBULL, professor of mining engineering in the University of Wyoming, has been examining mines in Sierra county, California.
LAMAR H. HUNT, formerly with the Sacramento Gold Mining Co. at Mercur, Utah, is now with the Minerva Gold Mining Co., at Atlanta, Idaho.

Obituary.

G. C. HEWETT died at Colorado Springs on August 12, the immediate cause being gastritis. He was 54 years of age and a consulting engineer of proved reputation, with a clientele among some of the best men in Colorado. He is survived by a widow and three sons, the eldest of whom is Foster Hewett, now on his way from Mexico to Peru.

ALFRED M. ROCK, a young mining engineer in the employment of the American Smelting & Refining Co., was killed by asphyxiation in the Santa Francisca mine, at Asientos, Mexico, on August 7. A fire had broken out in the mine, and Mr. Rock had gone underground as a volunteer to aid superintendent McMahan in placing bulkheads, and in seeing that the miners all got safely to surface. With master mechanic Gould, these men were the last to seek safety, but were all overcome after they had climbed to the first level and had started to crawl out a drainage tunnel toward the surface. A rescue party discovered them in

time to resuscitate Messrs. McMahan and Gould, but Mr. Rock was beyond recovery. After graduation from Harvard, Mr. Rock was for a time an assistant in the U. S. Geological Survey. He soon, however, entered into the employment of the Guggenheim companies, and at the time of his death, at the age of 29 years, was fast rising to prominence in his profession. Absolutely without fear, indefatigable in the performance of his duty, scrupulous in honor, and possessed of an unusually buoyant and cheerful disposition, Mr. Rock was a man who inspired respect and affection in all who knew him.

Owing to the strike of telegraphers, our reports from New York and London are not to hand up to the time of going to press.

NOME.

KETCHIKAN.

COCHISE COUNTY.

[illegible]

Map of Seward Peninsula.

GILA COUNTY.

The Old Dominion plant is treating a large tonnage of ore from its own mines and from the Warrior, Arizona Com-

mercial, and Gibson companies. A strike of 16 ft. of good ore is reported this week on the 280-ft. level of the Arizona National, while the Warrior Copper Co. is opening up a good body of ore that runs 9% copper.—Work progresses steadily at the Alsdorf property, under bond to the Lewishans, and which adjoins the Inspiration ground.—At the Old Dominion there seems to be an increase in the percentage of sulphur in the ore from the lower levels, so that it can go direct to the furnaces. Old Dominion ores have always been so low in sulphur that it was difficult to produce matte, high-sulphur ore having often to be shipped in from the Warren district, return shipments of Globe ore supplying a good acid material for the converter linings at Douglas. The Continental can always be relied on for a good tonnage of high-grade sulphide ore, and the Buckeye production continues large. Five furnaces are running at the smelter, the daily production averaging over 100,000 lb. copper.—About 12 tons per day are mined at the Eureka, which was leased by I. N. Kinsey. A small force of men is developing the property, and an orebody running 6% copper has been opened.—Three shifts are engaged in sinking the Great Eastern and Limestone shafts on the Superior & Boston ground, and in driving the west drift and sinking a winze on the Black Oxide.—Some rich samples of copper ore have been brought from the Sierra Ancha district, 50 miles north of Globe, by Joseph Faull and William McFadden. One shaft is down 100 ft. and the other 25 ft.—The Gem shaft of the Globe Consolidated is down 860 ft. and the Boston is 875 ft. deep.

MARICOPA COUNTY.

The Clark-Munger Co. is employing a small force of men and is trying to prove the existence of a body of copper ore. At the 43-ft. level in the shaft a cross-cut has been run and has already shown a little ore, and it is being extended as rapidly as possible to find the entire width of the orebody.—C. F. Smurthwaite, superintendent of the Grand Traverse & Arizona mine on Cave creek, reports that the main shaft of the property, known as shaft No. 1, is down 300 ft. and the workings are in sulphide ore. Hitherto the ore has been oxide.—There is news of a rich strike in Hualapai shaft No. 1, in the northern portion of the county. The strike was made on the 230-ft. level, where a 17-ft. vein of copper ore was encountered.—The Hualapai mines are owned by a corporation composed for the most part of Phoenix business men, and James Dobbins of that city is the manager.

YAVAPAI COUNTY.

(Special Correspondence).—The shaft on the Nigger Brown mine in Black Canyon district is down 175 ft., and in the last 20 ft. it is in a limestone and porphyry contact, in which a pay-streak of sulphide ore is being opened of undetermined thickness, some of which runs high in gold, with a little copper. The shaft is being sunk, and when the 200-ft. level is reached a station will be cut and the contact cross-cut. The mine is equipped with a hoist, and the eight claims comprising the group, situated 12 miles south of Turkey station, on the Bradshaw Mtn. railroad, cover valuable water and timber rights. This mine is among the oldest locations in the district, which was noted as a gold producer as far back as 1865. Caved workings of the miners of those early days are met with in many places, and many stone cabins, with post-holes still standing, recall the pioneer times. The Valencienne mine, which is reputed to have netted \$40,000 in gold, is situated a short distance south of the Nigger Brown.—Work on the May Mining Co.'s property, in Big Bug district, is to be resumed after a three years' shut-down. The plans of the company are to sink the shaft, now 237 ft. deep, to the 300-ft. level, where cross-cuts will be run to tap two parallel veins that have promising surface showings. The group consists of four claims, and adjoins the properties of the Arizona Exploration Co., known as the Blue Bell mines, on the northeast. The Blue Bell is now producing about 200 tons of ore per day, which is shipped to the Humboldt smelter. The May mine is equipped with a hoisting plant, with a capacity of 600 ft. A good wagon-road connects the camp with Mayer, the nearest railroad station, three miles north.—The business of the Humboldt smelter is rapidly in-

creasing on account of the greater activity in the Bradshaws and other territory tributary to it. The machinery has been ordered for increasing the capacity of the smelter, and the foundations are being laid.

Prescott, Aug. 12.

YAVAPAI COUNTY.

(Special Correspondence).—An excellent strike of copper ore is reported on the Little Daisy claim, belonging to the United Verde Extension Copper Co.'s group.—The new machinery for the Verde Grande is in place, and sinking will be resumed as soon as the shaft can be cleared of water. A No. 7. Knowles sinking pump is used. The main equipment consists of two 50-hp. Erie boilers, a 60-hp. steam hoist made by the Ottumwa Iron Works, one Ingersoll-Rand compressor with a capacity of 374 cu. ft. of air per min., and Ingersoll machine drills. Water for the boilers is pumped by air, from Walnut Springs, a distance of 750 ft., the raise being about 200 ft. The new equipment was sold by Harron, Rickard & McCone, of Los Angeles.—Work on the Arkansas & Arizona shaft is being vigorously pushed, under the direction of its new superintendent, Chas. Lynch. A 5-hp. engine and blower are being installed to keep the shaft clear of bad air.—A great deal of condemnation is openly expressed here regarding the advertising tactics employed by Stanton & Son, of Philadelphia, for the Hall Copper Co., of Jerome, and the management of the Jerome Verde Copper Co. (formerly the Verde Queen), in advertising its property. Both properties are considered valuable by local mining men, but the methods employed to advertise them are considered likely to do an injury to this district.

Jerome, Aug. 18.

CALIFORNIA.

NEVADA COUNTY.

Robert Johnson is developing the ground upon which antimony ore was found some months ago. During the prospecting work, a quartz vein was uncovered, but the ground is so deeply covered with overburden that it is difficult to prospect. A tunnel has been run in 125 ft. on an andesite dike, and will be continued farther.—The Oro Cobre Mining Co. has secured title to several claims near Cisco, in the Red Mtn. district.—On the property of the Sugar Loaf Mining Co., a pipe-line 2,000 ft. long will be laid, to bring water from the Snow Mountain ditch, under a head of 385 ft.—A double-compartment shaft will be sunk and a pumping plant installed.—A rich strike is reported in the Canada Hill Con. mine, formerly known as the Charonnat, at the 1,400-ft. level. The property produced about \$300,000, but the vein was lost on the 1,300-ft. level and the mine was closed down.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—Many of the large mines here have been closed down temporarily for want of coal, due to the big washout on the C. & S. R. R. in lower Clear Creek canyon, and now the same thing is happening again on account of the switchmen's strike on the same railroad, the road being unable to handle freight of any kind. Several new companies have been started in this vicinity and they are doing considerable development work. The Hagarstown Mining Co., of which Geo. A. Killam is the local representative, is operating the Darling group near Williams Fork. A contract has been let to open up the main vein, which runs the entire length of the property. The Hagarstown camp is entirely new, although the district has been prospected for years. It is expected that several mills, to treat the ores from the various lodes now being opened, will be erected before the end of the year.—

The Ruby Argentine Co., organized by Rees C. Widler and several Denver capitalists, has commenced operations in the Calla adit, now in about 700 ft. This will intersect the entire group of 13 lode claims: ore that milled \$32 per ton was shipped from the shaft workings years ago.—The Atlantic M. & M. Co. is employing a force of men in developing its property in the Atlantic district. Trenching is going on to prove the veins on the surface. A. A. Ireland, of Georgetown, the manager, believes that he will soon

have a paying property.—The Dewey M. & L. Co., operating in East Argentine, has encountered another lode in its cross-cut. Mr. Ireland reports that the ground is exceedingly hard.—A recent shipment from the Stemwinder on Columbia Mtn. ran 187 oz. silver per ton. There is now exposed in the drift six inches of high-grade sulphide ore, mill tests from which give 250 oz. silver per ton.—The Plebian is being worked through the Claypool tunnel on the same mountain, and some good quartz with scattered ore has been encountered.—The machinery for the Capitol Mining Co. has not yet arrived on account of railroad troubles, but the buildings are up and everything is in readiness for installation on arrival.—The Waukegan property, over Loveland pass, has been the scene of two rich strikes in the last week, six inches of ore that assays 290 oz. silver per ton and in the lower workings 14 in. of solid ore was opened up.

Georgetown, Aug. 10.

SUMMIT COUNTY.

Several shareholders of the O'Reilly Gold Mining Co. have recently been in Breckenridge. H. E. Houghton is president of the company; M. E. Burke, treasurer; Wilbur Treadwell, consulting engineer; and Arthur C. Howard, mine superintendent. The organization was completed six months ago, and since that time 250 ft. of development work has been done.—Shareholders of the Mary Verna and North American companies have been visiting the properties. The Summit company has taken a lease on all the ground above the tunnel level of the Mary Verna, and production will start as soon as the 2,000-ft. tramway is built.—The east drift in the upper workings of the Wellington property is showing some good ore.—Morris, Irwin, and associates are overhauling the West Side mill, and it will run on ore from the Gold Dust mine.—The new tunnel on the Country Bay property is in 125 ft., and will be continued to the 1,100-ft. point.—The Blue Flag mill, near Argentine, is running satisfactorily, and is making a good saving.—The new generating plant for the Arctic mine is being erected, and water-power near the head of the Blue river will supply the machine-drills with electric power.—The Senator tramway and mill are being erected as rapidly as possible, and development continues at the mine.—A contract has been let for 100 ft. of tunnel on the Gold Belle property on Mt. Baldy.

IDAHO.

KOOTENAI COUNTY.

What promises to develop into a good vein of copper ore has been opened at water-level on the Kootenai No. 2 property in the Priest Lake district, north of Spokane. The property lies at the head of upper Priest lake, eight miles west of the Continental mine. The vein exposed in the shallow shaft was 8 ft. wide, and carried 4 ft. of ore that assayed \$50 per ton, with 9.8% copper. Since then the shaft has been deepened a few feet. A new cropping 27 ft. wide was discovered on the property, and traced 900 ft. Andrew Coolin and Edward Moulton control the property.—Steps have been taken by the owners of the mining property near Hayden lake, east of Spokane, to incorporate, designating the property the Hayden Lake Mining Co. Those interested are John Boothe, Isaac and Jasper Cooper, James Baker, and B. Kling, of Coeur d'Alene. The property is on the mountain, near the lake, and when completed it is expected the ore will be within half a mile of the lake shore, whence it may be hauled on barges and put upon the electric line. The ore is chiefly copper, yielding in some instances as high as 11%. Gold and silver also are found in limited quantities.

NEZ PERCE COUNTY.

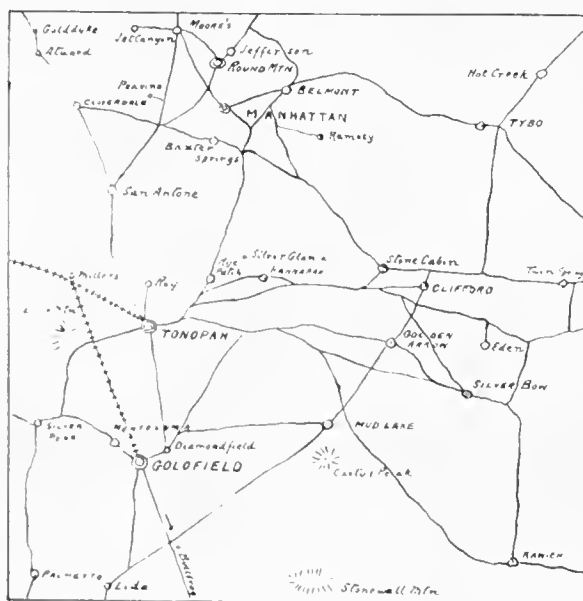

W. H. Hare, who has just returned from a trip of inspection to the property of the Idaho Mining Co. of Pierce City, says that much development work is going on throughout the district. On the Wild Rose, which is controlled by the Jellum & Jones Co. of Lewiston, surveyors are running the lines for a tunnel near the new millsite on a water-right recently secured. S. P. Jellum is superintendent of the work.—The American, one of the oldest properties in the

district, is now being operated by J. M. Porter of Spokane, and the showings are the best made in the district for some time. An elevator has been installed, and is now moving an average of 400 yards of dirt daily, which runs as high as 23c. per yard. A. J. Culver has installed a pump on a high bar near the Wild Rose, forcing water 300 ft. above the creek bottom. The Idaho Mining Co. is on a dividend basis and purposes installing elevators near the dredge now at work.

NEVADA.

ESMERALDA COUNTY.

The product of the Goldfield mines for the week ending August 17 is reported disposed of as follows: Shipped to smelters, 470 tons; shipped to Nevada Goldfield Reduction Works, 2,072; to Western Ore Purchasing Co., 708; treated at Combination mill, 560 tons of ore, making a total of 3,810 tons, with an estimated value of about \$400,000. This is the third heaviest production of any week in the history of the camp. The Frances Mohawk lease No. 3 will soon enter the list of regular shippers, and it is thought that the present rate of production for the camp can be maintained for

Part of Nevada.

some time. The Nevada Goldfield Reduction Works receives shipments of ore as follows, during the week: Mohawk Florence, 162 tons; Little Florence, 369; Hayes-Monnette dump, 88; Mohawk mine, 350; Mohawk Combination, 640; Higginson, 112; Red Top, 200; McNaughton lease, 75; Rogers Goldfield Syndicate, 53; Black Butte Consolidated, 18; Frances Mohawk, 5. Total, 2,072 tons. Average estimated value, \$125 per ton. Total mill value, \$259,000. For the same week the Western Ore Purchasing Co. received consignments of ore as follows: Mohawk Ledge, 77 tons; Combination mine, 107; Mohawk Jumbo, 524. Total, 708 tons. Average estimated value, \$125 per ton. Total mill value, \$88,500.

A small shoot of ore was recently struck on the Nevada Pearl property on the Combination southeast of the Little Florence, but it soon pinched out. The operators expect soon to cut a permanent orebody. The Jumbo Annex Company, operating a sub-lease of the Higginson, reports having struck what is supposed to be the Higginson-McNaughton ore-shoot at a depth of 175 ft., although the ore as found is neither rich nor of any great extent. The shaft is down 240 ft. and a cross-cut is being driven toward the vein on that level.—The shaft of the Goldfield Great Bend is down 300 ft. and cross-cutting is proceeding. Work on the 200-ft. level will be resumed at once.—At Black Butte, two shifts are again at work on the Midnight Pawnee. The shaft is down 95 ft. and will be sunk to water-level. Webb Parkison owns the controlling interest.—A heavy flow of water has been struck in the north drift from the west cross-cut in the Combination Extension mine.—A. J. Canavan has been appointed superintendent of the Mo-

hawk mine, succeeding F. J. Healy.—The winze that is being sunk from the 385-ft. level on the Florence L. & M. Co.'s ground is down 40 ft., with ore showing all the way.

NEW MEXICO.

TAOS COUNTY.

Ninety men are on the payroll of the Victoria Chief Copper M. Co., in the Caballos Mtn. One tunnel has been run 650 ft., and some good copper ore has been opened. One carload of ore has been shipped, and a wagon-road to Cutter has been built.—J. T. Heathman has sold an interest in the Bartlett mining property, at the mouth of Columbine river, eight miles below Red River, to Eastern parties.—The Keystone drilling machine for the Barmar Gold Dredging Co. has arrived, and is being hauled to the property on the Rio Grande river.

SIERRA COUNTY.

The final payment has been made on the Ocean Wave group of claims at Hermosa. Development will be pushed and a 10-stamp mill will be erected.

SOUTH DAKOTA.

PENNINGTON COUNTY.

W. W. Trimpi, representing New York men, has just purchased the old Mainstay mill for \$7,000; it originally cost \$100,000. All the back debts of the company will be paid, and work will be resumed.—Some rich sand has been found in the shaft of the Holy Terror mine. The shaft is being unwatered.—At Keystone, the mica property of Charles Upham has been bonded to an Eastern company represented by Joseph P. Labaw. E. N. Ball will have charge of work at the mine.—A rich ore-shoot has been struck on the Jo Dollar property, west of Keystone, in a tunnel that has reached a depth of 100 ft. George Karr has a lease on the property.—It is said that a good vein of ore has been struck on the ground of the Leo Mining Co., on Box Elder creek, near Benchmark, at a depth of 190 feet.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The adit of the Winnipeg mine, in Beleher district, is in 1,070 ft. and is connected with the shaft. E. R. Fraser, president of the company, is at the mine.—The cross-cut from the No. 2 adit of the Copper Key mine has intersected 68 ft. of ore, and is believed to have reached the hanging wall.—The British Columbia Copper Co. will construct an aerial tramway from the Lone Star and Washington mines, to its smelter, at Greenwood, B. C., according to a report from Danville, near where the mine is situated. The ore reserves on this property are increasing with development.—A new body of marketable ore has been encountered in the No. 3 adit of the Lucile Dreyfus mine, near Danville.—An automatic blower and 500 ft. of 4-in. galvanized iron pipe have been installed at the Humboldt mine, near Kellar.—At Meteor camp, the Syndicate M. & M. Co. has 15 claims in a group, with several veins of gold, silver, and lead ore, from 6 in. to 2 ft. in width, and one vein 30 ft. wide. J. W. Bartlett, the manager, says the latter shows fine grained galena, carries some gold, and the average value of the ore is about \$27 per ton. An adit, starting from Stray Dog canyon, to develop the group, is in about 300 ft., is expected to tap the first vein 75 ft. further in, at a depth of about 400 ft., and will have about 1,500 ft. in all to run to tap the widest vein, at a depth of 800 ft.—Drifts are being driven northerly and southerly from the adit, on the vein at the Meteor mine, resulting in a production of one to two tons of ore per day. The selected ore is sacked.—The Longstreet group of three claims covers a vein over 30 ft. wide, which yields antimonial silver and gold ore in quartz gangue. Some of the ore is stibnite. An adit is being driven to cross-cut the vein. The Advance mine is idle, but work on it will soon be resumed.—The Black Thorne Mining Co. (principal place of business Davenport, Lincoln county, Wash.) has three claims. A vein, 30 in. wide at the surface, yields galena, and assays in gold and silver. An adit is in 850 ft., and at about 50 ft. further in should strike the vein at a

depth of 300 ft.—The Keystone group has six claims. A vein three feet wide has produced some gold-silver-lead ore and is being further developed by an adit. George Mathews, of Davenport, is the manager.—The Covada mine, at Covada, embraces three claims in a group. A vein from 6 in. to 2 ft. wide yields gold-silver-lead ore. It has been opened by shafts and adits. The main adit is in 270 ft. on the vein.

Republic, Aug. 19.

OKANOGAN COUNTY.

(Special correspondence).—The Palmer Mountain T. & P. Co., at Loomis, has advanced its adit 300 ft. since resuming work, and it is now in about 4,300 ft. The frame of the mill is nearly completed, and the machinery is beginning to arrive. A new turbine water-wheel has been installed at the electric plant in place of one that was shattered last spring by a freshet through Toats Coule.—At the Copper World Extension mine a drift has been driven west on the hanging wall of the vein, on the 200-ft. level, for 200 ft., and another is in over 100 ft. toward the east. Where the vein was intersected by a cross-cut from the shaft it is 23 ft. wide, and other cross-cuts from the drifts have proved it to vary from 20 to 30 ft. wide. The ore is pyrrhotite and is reported to assay 5% copper. The company has decided to build a two-mile aerial tramway from the shaft, down the side of Palmer Mtn., to the wagon road alongside Palmer lake, whence the distance to the Vancouver, Victoria & Eastern railway is five miles. It is thought probable that a spur of the railway will be built from the head of the lake to Loomis.—At the Kimberley mine, at Golden camp, power drills are used for driving on the vein on the 100-ft. level. The ore is of good grade, and preparations are being made for regular shipments to the smelters.

Republic, Aug. 19.

BRITISH COLUMBIA.

The coke shortage still prevails; but relief has been promised by the fuel dealers. Le Roi has ceased to ship ore to Northport, but will keep about 150 men at work on development and breaking ore. Some repairing to the timbers in the shaft is necessary, and while this is being done most of the men will be laid off, although shipments to Northport will probably be resumed within 30 days.—During the week ending August 10, the Rossland mines shipped ore as follows: Centre Star, 2,220 tons; Le Roi, 1,155; Le Roi No. 2, 260; White Bear, 260; Nest Egg, 35. Total, 3,910 tons.—At the Centre Star, the prospecting shaft on the Idaho is down 35 ft., and development continues on the War Eagle, Centre Star, and Iron Mask properties. As the smelter is running at reduced capacity, attention is confined especially to development.—The Nest Egg, under lease to Mr. Webb, sent a carload of ore to the smelter this week, which is the first ore sent from a south belt mine in a good while.

The Consolidated company's Trail smelter received during the week consignments of ore in addition to Rossland shipments as follows: Snowshoe, 944 tons; Victoria Nelson, 80; St. Eugene, Moyie, 366; North Star, East Kootenay, 62; La Plata, Kokanee creek, 50; Arlington, Sloean, 34; Payne, Sloean, 30; Arlington, Erie, 24; Queen, Erie, 23; Rambler-Cariboo, Sloean, 23; Standard, 23; Bachelor, 22; California, 22; Vancouver, 21 tons of ore.—Ore shipments to the Northport smelter have ceased, as it will have to close until a coke reserve is had in stock, but 1,155 tons of ore were received from Le Roi during the week.

The Boundary mines made a good record of shipments during the week, in spite of the shortage of coke and cars. The shipments were as follows: To Granby smelter from Granby mines, 15,543 tons; Emma, 300.—To B. C. Copper Co.'s smelter from Brooklyn, 1,184 tons; Idaho, 929; Rawhide, 2,048; Sunset, 1,280; Mountain Rose, 256.—To Trail smelter from Snowshoe, 1,450 tons; from Providence, 30 tons. Total shipments for week, 32,036 tons and for year to date, 711,342 tons.—Boundary smelters treated this week as follows: Granby smelter, 16,583 tons; B. C. Copper Co.'s plant, 11,467; Dominion Copper Co.'s smelter, 5,697. Total treatment for week, 33,747, and for year to date, 697,793 tons of ore.

Reports from Cariboo state that T. B. Hobson, former manager of the Guggenheim interests in that district, has resigned and has been succeeded by Mr. Copeland. The Guggenheims will not abandon their scheme at Bullion, but will probably proceed a little more conservatively with the big ditch on which they have spent so much money.—C. F. Caldwell and G. Gervais have recently returned from the new copper discoveries on Burwash creek in the Kdaunr district, and they report that the country shows some promising prospects.—Several of the shareholders of the Vancouver Island Copper Co. have recently visited the property at Sidney Inlet. A contract has been let to the Riblet Tramway Co. for an aerial tramway with a capacity of 200 tons per day to connect the mine and the ore-bins at the wharf.—E. Lindman, the expert sent out by the Dominion Government to investigate the mineral resources of Vancouver island, has gone to the west coast, and will make a survey of the districts of Sechart and Sareta.—Henry Bahrs has taken a bond on a group of claims three miles from Delmar, in the Similkameen district, near the property of the King Edward Mines Co.—After lying idle for several years because under bond to Pittsburg parties, the Snowytop mine will be worked by a company composed principally of Detroit men, including A. I. Marinette and A. S. Brown.—The Hewitt silver-lead mine at Silvertown

Fuel company is having plans prepared for the bunkers to store 10,000 tons of coal in Spokane.

A late report from Grand Forks says that a tremendous cave-in at the Brooklyn mine in Phoenix camp occurred, the ore bunkers and all below for 300 ft. by 150 ft. wide fell in, taking the tramway track as well as some mining machinery. This cave-in will put the Brooklyn mine out of business for many months. The cause is reported to be that work has been carried on too close to the surface. No one was hurt by the accident, but the damage done will reach many thousands of dollars.

MEXICO.

CHIHUAHUA.

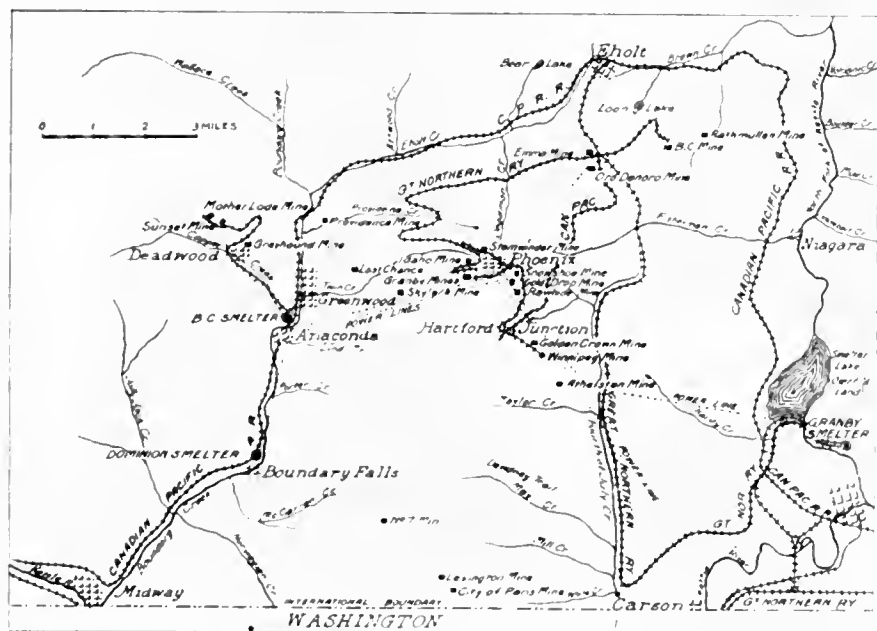

The new Parral Mines Syndicate will start development work on La Union mine, near Vencedora, as soon as the pumps arrive for unwatering the shaft.—The new three-mile aerial tram from the Palmilla mine to the railroad has been started and is handling about 60 tons per day.—Work is progressing well at the properties of the Hinds Consolidated Mining Co. of Santa Barbara. A vein has recently been cut in the Reforma that runs well in lead, copper, and silver.—The shaft of the Santa Eulalia Union M. Co. is down 120 ft. John Lufkin is the superintendent.—At the mine and mill of the Rio Plata Mining Co., near Guazapares, 150 men are employed. Six tunnels are being run and 250 ft. of work has been done in the last 60 days. D. W. Shanks is the manager.—J. M. Sully has made the first payment on the purchase of the Corregidora gold-silver mine, not far from Guazapares.

JALISCO.

Los Angeles capitalists, represented by J. F. Buel, have purchased the mines of the Jalisco Mining Co. in the San Sebastian district. A payment of \$25,000 has been made, and three years time was given for the payment of the remainder. The mines of the Jalisco company have been managed for several years by Alfred Loneragan, and have always been producers. The reduction plant contains stamps, Bryan mills, a Krupp tube-mill, concentrators, and a patio for amalgamation.—The Amparo Mining Co., operating at Emboada in the Etzatlan district, is employing 1,200 men. The new reduction plant will be in operation in October. Ferdinand Sustersie is the manager. The company has recently filed an application for a concession on the water of the Ameca river, to use in a hydro-electric plant.—Lowering the water in the Casados mines in the Hastolipaquillo district continues, and some rich ore has been struck. J. D. Dotson is the treasurer of the company, and A. H. Mugford is now examining the properties.—The new pump is being installed at the Tenamache mines in Tepic, and the unwatering of the mines will soon start. W. R. Ramsdell is the president of the Tenamache Mining Co., and Amado Aguirre is in charge of the work.—The Mexican Western Development Co., which recently purchased the Santa Eduvigis, Rosario, Valenciana, La Luz, Delicias, and Restauradora mines at Bramador for \$300,000, will build a wagon-road from Bramador to Chamela, a Pacific port. Frederick R. Burnham is the manager.—The Maduro Mining Co. has purchased the Buenavista mine at Jora. This adjoins the famous old San José de Ventanas property. H. M. McIntosh of Chicago is president of the company, and W. H. Lees is manager.

SONORA.

The Lewisohns have purchased the Cananea Nueva mine of Lindsay & Talbot, comprising 1,200 pertenencias north of the Greene-Cananea, on the other side of the granite core.

Part of British Columbia.

has been optioned to New York parties, represented by Olcott Payne. George Stillwell will remain superintendent of the property.—Mining at Lillooet is active. On Alexander and Cayuse creeks hydraulic operations will soon start, and a good vein has been struck in the Lorna mine, which will be extensively developed.—In the Mt. Sicker district, a new orebody has been found in the north vein on the ground of the Tyee Copper Co. The Copper Canyon mines are in good shape, and have been recently acquired by a Philadelphia syndicate, with James Humes as manager.—Work on the Loyal group, Texada island, has been suspended pending negotiations for its purchase. Development work was started a year ago by C. H. Jacobs and associates, and resulted satisfactorily. The mine was once a shipper of copper ore, and is owned by H. W. Treat; it is situated four miles northwest of the Marble Bay mine.—Domestic coal for the Spokane and Inland Empire market will be shipped from Alberta next fall and winter, the latest addition to the list of producers being the Royal Collieries, Ltd., which has acquired the Barnes mine at Lethbridge, Alberta, and 6,000 acres of coal land adjoining, north of Spokane. The principals of the concern are: A. C. Plumerfelt, H. N. Galer, and Andrew Laidlaw. An arrangement has been completed whereby the Alberta Fuel company of Spokane and Calgary, Alberta, will handle the output of the Royal collieries, and with this end in view the Alberta

Special Correspondence.

London.

Cornish Mining.—Dolcoath Shaft.—South Crofty.—Production of Wolfram.—Financial Methods.—Tomboy Returns.—Mexican Mines.—The Deep Leads.—Depreciation in Kaffir Stocks.

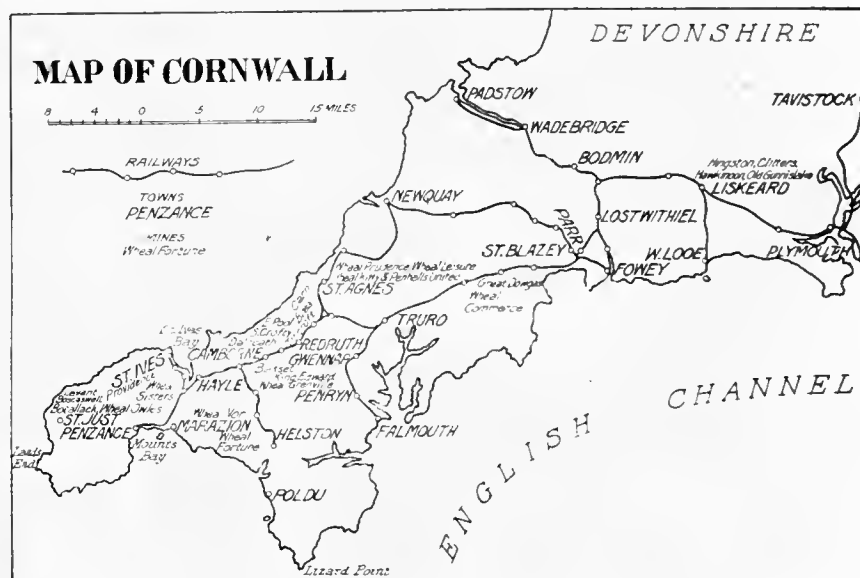

Three sales of black tin took place at Redruth during July, the quantities dealt with being 254, 196, and 241 tons respectively. The average price obtained at the last of these was £110 9s. 6d. or £7 10s. 7d. less than at the 'tieketing' on July 1, but still higher than for the corresponding sale in 1906 by nearly £12 per ton. Cornwall must buck up in the matter of quantity if the current year's sales of black tin are to show an appreciable increase on last year's total—6,227 tons—itself less than for 1905 by 104 tons. The Dolcoath mine—Cornwall's principal tin producer—shows a slight increase for the half-year ended in June, as 51,243 tons were crushed, and the amount realized by the sale of the product was £104,094, against 50,245 tons treated and £101,374 realized for the previous half-year, while in the first six months of 1906 the quantity crushed was 49,934 tons and the sales amounted to £97,268.

According to the *Cornish Post* the proposal to sink the Williams shaft on the Dolcoath property in its present form was described by the manager, Mr. R. Arthur Thomas, to visiting members of the Royal Cornwall Polytechnic Society, as not only politic but economically sound. It might, he said, cost from 3 to 4% more than a rectangular shaft would cost; and not only would a circular shaft make for greater security, but it would allow them to do what was essential to deep mining—it would permit of the conveyance of huge quantities of cold air for the workers 500 fathoms deep. As to the temperature in Dolcoath, the late Capt. Josiah Thomas made some tests which showed that the temperature of the rock 354 fathoms from surface was 83° and the temperature of the air 81°. The bottom of the mine is now over 3,120 ft. from the surface, and Mr. Thomas says the new shaft will be useless unless it is made capable of conveying a good supply of cold air.

The first annual report of South Crofty, Ltd., states that the sales of tin, wolfram, and arsenic for the period from July 18, 1906, to June 30, 1907, amounted to £22,993. The profit was £1,011 and the directors consider it a matter of satisfaction that they have been able to cover all the working expenses during the period of reorganization. Only 32 heads of Cornish stamps have been running. The underground developments are now considered to be far ahead of the 40-stamp Californian mill. The remaining 32 heads of Cornish stamps are being taken out in order to make room for an additional 20 heads of Californian stamps. The ore proves highly complex, but several wolfram sales have already been made at an average price of £150 per ton, and further experiments are leading to a still better separation of the wolfram.

Regarding the developments on the New Cook's Kitchen property under covenant with Mr. Basset, the landlord, a new vertical shaft has been started and it is

now down 140 ft. This has passed through one branch, about 18 in. wide, carrying galena, arsenic, and copper. The shaft will be continued to 195 fathoms. Somewhere between 90 and 120 fm. the manager expects to cut what is known as No. 1 lode. As to the battery, 30 of the 40 Californian stamps are working, and the remaining 10 will start immediately. They are running at 106 drops per minute, with a total drop of 7½ in., using a 25-mesh screen. These stamps are electrically driven; the power taken amounts to about 1s. 2½d. per ton crushed, which should come down to 11d. per ton when the battery is in full swing. The 40 heads are to be supplemented at Easter next year with a further 20 stamps. The 60 stamps, when the rock-crushing plant is in full working, will do a duty of 3½ tons per head and a profit of 20s. per ton is anticipated or, say, £200 per day. The working capital of the Company (£25,000) being exhausted, 4,000 of the reserve shares are to be offered at £4 per share to carry on the mine. This will bring up the total number of shares issued to 44,000. Of these 20,000 were originally handed over to the original proprietors. It now transpires that these Cornish stockholders have parted

with some two-thirds of their holdings to Londoners who have been engaged in writing up the mine until the price of the £1 share has risen to over £6. The future will show whether the men of the East or the West have proved themselves the most far-seeing. Meantime the first dividend is promised for Christmas.

Tomboy returns for July, 1907: Mill ran 29 days and crushed 9,300 tons of ore; estimated realizable value of the product, \$50,000; concentrate shipped, 520 tons; estimated value, \$33,000; total for the month, \$83,000; less working expenses, \$43,000; estimated profit, \$40,000. Expenditure on construction or improvements (not included in above expenses), \$2,290.

The net proceeds of Mexico Mines of El Oro for July are estimated at \$60,000. Dolores' profit for June was \$60,000; the directors of the English company have declared a third (interim) dividend of 3% payable on August 24.

Stockholders and brokers who some nine months ago were described as puzzling over the meaning of cabled reports concerning the extent and value of the 'wash' made accessible on the Loddon Valley Co.'s property must have found the last report issued by the directors much more definite. The report states that the wash has been entered at five or six points. Some of these showed rich wash, but the rich areas proved too local in extent to be valuable as a working mine. At No. 5 raise, however, a run of gold was found which proved at this point

to carry 14 dwt., 16 gr. per fathom for a width of 275 ft. Only a small portion of the company's ground has been explored, and the continuation of this 'run' can only be ascertained by further expenditure. Of the issue of 80,000 shares, 72,827 were subscribed, and as the Company is left with a debit balance at the present time of about £30,000, further money must be raised to meet the liabilities and continue operations. The report adds that the Government of Victoria has offered to lend £8,000 for the purpose of extending the 500-ft. level due north and south. It is necessary, however, under the terms of this offer, that the Company should set apart an equal amount for this special work. The directors find that it will be necessary to ask the shareholders to agree to further funds, to the extent of 5s. per share, being provided by the adoption of the reorganization scheme.

Attention is drawn to the evidence given before the Transvaal Mining Industry Commission of the depreciation that has taken place in the market value of Kaffir mining shares since the year 1902. Taking the dividend-paying mines, the Consolidated Goldfields group, which in 1902 had an issued capital of £4,392,359, of a market valuation of £13,530,553, has, after having added some £231,000 to its issued capital, a valuation of only £10,094,332. The Eckstein group, which increased its issued capital during the period by £95,278, shows a depreciation in market value of £11,217,889 at £16,062,007. The loss on Rand Mines issues amounts to £10,763,750; on the Johannesburg Consolidated Investment group to £4,058,773; or the Neuman companies to £1,524,121; on the J. B. Robinson group to £1,479,187; and on Goerz issues to £1,602,422. On the other hand, the Farrar Anglo-French group, which has increased its issued capital by £1,368,750, and the General Mining & Finance, or Albu, group, which has added £100,000 to its capital, show improvements in market valuation of £706,250 and £137,500, respectively. Including sundry mines, the depreciation amounts to £34,199,551, while in the case of producing but non-dividend-paying mines the depreciation is £11,889,913.

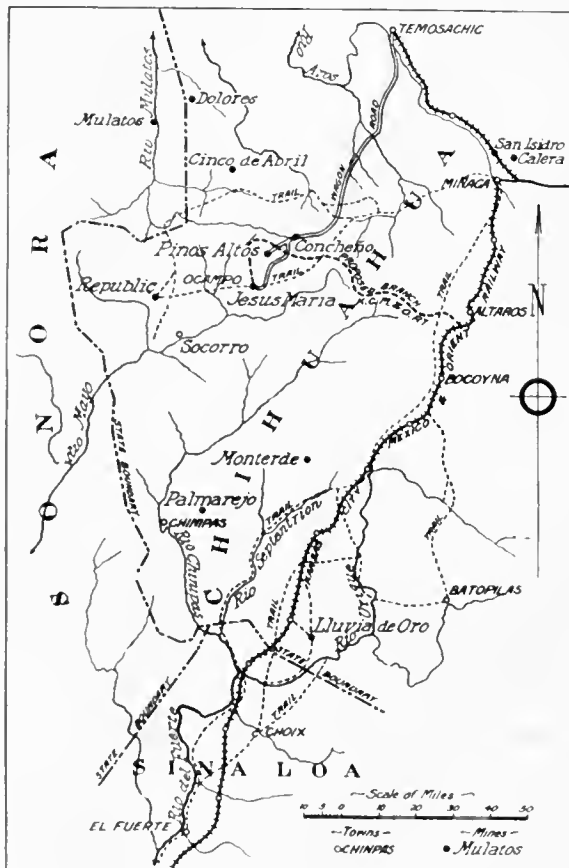

Mexico City.

A Curious Ejectment.—Litigation Likely.—The San Toy Co.—Bad Railroad Service.—Satirical Comment, Fully Warranted.

The mining interests in and about Chihuahua have been greatly excited during the last month by the action of one of the Federal District judges in dispossessing and forcibly ejecting J. P. Hutchinson from the Dolores mine in the Santa Eulalia district, which is held under option from the Escobar estate, whose title to the same was looked upon as one of the oldest and safest in this region. It seems, however, that the new mining law has some proviso that requires an exchange of these old titles for new ones, but which is not understood generally and in the case of the Dolores was not done by the Escobar estate. Learning of this Aguirre Nevarez entered a new denouncement covering part of the Dolores and when his titles were obtained sought and obtained possession through the courts. Mr. Hutchinson has taken the matter to Mexico City, and as it is claimed that both Schwab and Heinze are behind him, it is liable to be a big fight. Should the judge be sustained in his ruling, it will be hard to say whether any of the old mining titles in Mexico are worth more than the paper on which they are written. It is to be hoped that the injustice may be righted and the judge of the 5th Sala in Chihuahua may be looking for another position.

The San Toy Mining Co., which is also in charge of J. P. Hutchinson, has started its direct shipments to the Torreon smelter, using its new aerial tram and switch to

connect with the Mexican Central, at the rate of 50 or 100 tons per day, depending upon its ability to get cars. Almost all the other ore shipments from the Santa Eulalia district, which are contracted to the American Smelting & Refining Co., are practically cut off, with the exception of a couple of hundred tons per month to the Monterey plant, because of the inability or refusal of the Mexican Central to furnish cars, as this Santa Eulalia ore is usually billed to the El Paso smelter, and the yards there now, especially on the Mexican side of the river, are so full of cars that since August 1 the railroad has refused to receive more northbound shipments. This condition is due almost wholly to the fact that the Mexican Central has been so short of motive power that it could

not handle the freight given it, all its yards and side tracks got filled, and then to clean up the northern division engines were rushed up from the south and the long overdue cars sent on so unsystematically and hurriedly that they simply swamped themselves. But the company's inability to handle its freight has not been recent, for on the Chihuahua division alone the conditions have been such that for the last 18 months the Santa Eulalia mines have not been able to produce to more than half their capacity, simply because they could not ship the ores after they were taken out of the mines. And the same condition is said to exist over the entire Mexican Central system. C. R. Hudson, the vice-president, and H. Lawton, the freight traffic manager of the Mexican Central, have just returned to Mexico City in their private cars from an inspection of the main road from Mexico City to El Paso, and there is a rumor to the effect that the road and service was found to be in such a deplorable shape that serious consideration is being given to the advisability of tearing up the tracks and selling them for scrap iron, putting the ties on the market for kindling wood, punk, or peat, utilizing the coaches for way stations, and equipping the road with traction engines in order to insure more rapid

and safe dispatch of both freight and passenger service. And it is understood that some four or five of these traction engines and wagons are now available for the northern division of the old smelting plant of the Encinillas Mines Ltd., at Santa Rosalia, Chihuahua.

Butte, Montana.

The Western Federation and the Local Union.—Butte Montana Co.—Fire in the Minnie Healey.—Strike of Machinists.—The Lewisohns and the Montgomery Claims.

Officials of the Butte miners' union say the vote of the union, at a recent special election, endorsing the Western Federation constitutional amendment making it unlawful for local unions to enter into any contracts with employers relative to wages, hours, etc., for any specified time, applies only to the future and is not retroactive. President Duffy of the union declares that the Butte miners will live up to their contracts made with the mining companies several months ago, when they agreed to accept \$4 per day as long as the price of copper was at or above 18 cents per pound, and to return to the old scale of \$3.50 per day if the price of copper falls below 18 cents and remains there for 30 consecutive days, that agreement to be in force until 1912. When the Western Federation adopted the constitutional amendment it was reported that all existing contracts would be annulled, and that it was specially aimed at the Butte contracts. The assurance of the Butte union officials that the miners will live up to the contract is welcome, as it had been freely predicted that the miners would repudiate the contracts the moment the question was put to them; it was generally feared that they would refuse to go back to the \$3.50 rate and that a shut-down of the mines would result.

The Butte Montana Mining Co. took up the bond on the Alex Scott mine at the last minute, just before the expiration of the option. The company has a large number of stockholders, who purchased stock at prices ranging from 50c. to \$2, and they were fearing that they would have the same sad experience that befell the victims of the Butte Exploration Co. Some Pittsburg people backed the enterprise, but when it came to putting up \$130,000 for the final payment on August 15 they could raise only \$60,000, which sum was wired to Butte. To save the company the Butte men interested raised the balance necessary to take the deed out of escrow. The Alex Scott is a well situated property, near the Leonard mine of the Boston & Montana Co., and a lot of development work has been done on it.

All the gas caused by the fire underground has been driven from the Minnie Healey mine, and work has been resumed in that property by the Butte Coalition Co. It is now believed that the fire started in the old stopes of the Leonard mine, owned by the Boston & Montana Co., and worked its way over into the Minnie Healey. The gas is still strong in the Leonard and the West Colusa mines, which connect with the Minnie Healey. There is a suspicion that the fire may have been of incendiary origin, but the prevailing belief among miners is that it resulted from spontaneous combustion in the old inflammable material used in filling up the old stopes. While the gas was at its worst in the Minnie Healey the ore production of the Coalition Co. was cut off about 400 to 500 tons per day, but the output is again being restored to its maximum, and in another week, it is expected, the output will amount to 1,800 tons of ore per day. The ore from the Minnie Healey comes from the 1,000 and 1,100-ft. levels, and is hoisted through the Leonard shaft. A connection is being made between the 1,100 of the Minnie Healey and the 1,300 of the Rarus, and when

completed some mining will be done through the Rarus. The 1,300 is the next level below the 1,100 of the Minnie Healey, but no mining has yet been done there; an engine is being installed on the 1,100, and will be completed in a few days, when mining will be started on the lower level, where some fine orebodies have been opened.

The strike of the machinists, which has lasted for several weeks, has not yet interfered with mining operations, although every machinist employed by the big companies has gone on strike. There were about 200 employed at the mines, and they did all the repair work on the engines, machine-drills, etc., put in the pipes, and did the work on the new hoisting plants that were in course of installation when the strike was declared. It was expected by the machinists that as soon as an engine became impaired, or the machine-drills required repairing, that mining would have to be suspended, and the companies would be forced to a settlement. However, the miners, who are not in sympathy with the machinists' strike, would not risk throwing 10,000 miners out of work, and when repairs on engines or drills became necessary they made the repairs themselves. Miners have also put in necessary piping in mines, and the only work they have not taken off the hands of machinists is the installation of engines and other surface machinery. That class of work has been stopped. About 10 days' work remained on the new engine and hoisting plant on the Tramway when the machinists went on strike, but as the Coalition Co. will not be ready to make use of that plant for two or three months it is not much concerned about the delay. When the miners got a raise in wages and signed a five-year contract the machinists were offered \$4.75 per day, but they refused to accept less than \$5 per day or to sign a contract. They were informed that if they were not satisfied with what was offered them they could strike, and they did so at the first opportunity.

A vein of ore six feet wide has been cut in the Elm Orlu in a cross-cut at 500 ft. The Elm Orlu is being developed by W. A. Clark. Assays give 2% copper, 100 oz. silver, with some gold and lead. The shaft is nearly 600 ft. deep and is to be sunk 1,500 ft. The shaft is near the west end-line of the Elm Orlu and near the east end-line of the Poser, it being so situated that both claims can be developed through it. The Elm Orlu vein is one that strikes through the Pilot claim of the Pilot-Butte Co., and its development by W. A. Clark has added to the confidence of the Pilot people.

The Raven Mining Co. is making good progress in development. The Raven shaft has reached a depth of nearly 900 ft. and driving on the vein is being done at 700 ft.—The Pittsburg & Montana Co. is mining at a depth of 1,500 ft. through winzes from the 1,200-ft. level, and from 200 to 280 tons of ore is being shipped daily. The two principal veins in the Pittsmont ground are being connected by cross-cuts from the winzes. Shaft No. 1 is down 1,400 ft. and cross-cuts are being run from the bottom of it to the veins.

The failure of the Lewisohns to take up a bond on the Montgomery group of copper claims on the east side of the Butte district has resulted in a suit being brought against them by John McBarron, a promoter, who had the bond on the properties from Henry Brundy and assigned it to Adolph Lewisohn. The McBarron bond was for \$200,000 and Lewisohn agreed to give him \$100,000 for his interest, according to McBarron's claim. He was to be paid in five installments, but only \$4,000 was paid and then a new agreement was drawn up under which the Montana Consolidated Mining Co. was organized by Lewisohn, capitalized for 2,500,000 shares of \$1 each. The company was to take over the Brundy prop-

erties and also take in a lot of other mining interests owned by Lewisohn in the Butte district, including the Granite Mountain and Flatiron claims, which are undergoing development. McBarron says he was to receive \$21,000 cash and 75,000 shares of the stock of the new company, but he has received neither, and the company has abandoned the Brundy bond. The defendants named are Adolph Lewisohn and J. H. Sussman, of New York; J. Parke Channing, the consulting engineer, upon whose report the bond on the Brundy properties was thrown up; H. Clifford Wilmot, mining manager for the new company; Herman Cook and John F. Ryan, president and secretary, respectively, of the Montana Consolidated. An attachment has been levied on the Lewisohn properties in Butte, including the Granite Mountain and Flatiron, and half a dozen other mining claims.

Toronto, Canada.

The Strike.—Some Mines Re-open.—New Discoveries.—Explorations Along the Railway.—Ore Shipments.

The strike at Cobalt is assuming a more acute phase owing to the tactics adopted by the Western Federation of Miners in inducing men (engaged to take the places of strikers) to quit work. Thirty-seven miners, brought under contract from Sydney, Nova Scotia, who arrived at Cobalt on the 9th inst., were surrounded by strikers on their arrival and persuaded to join them. They had signed a contract which embodied an acknowledgment that a strike was in progress, but state that they were informed by the agent engaging them that the trouble was practically over. Others arriving since have also been secured by the strikers. As a counter-move an injunction was secured yesterday by the Buffalo Mines Ltd. restraining Cobalt branch of the W. F. of M. from picketing, boycotting, persuading miners to break contracts, or otherwise interfering with employees.

The King Edward mine, closed since the beginning of the strike, has resumed work, paying union rates, but maintaining the open-shop principle. The Colonial, under the same management, will shortly re-open. At the La Rose seven drills are in operation with double shifts. The Nipissing has 10 machine-men operating drills and a number in training. Over 300 men in all are at work. The O'Brien has 125 men employed, mostly in surface operations.—At the Coniagas 110 men and five drills are in operation.—The Foster, which has conceded the strikers' demands, has 75 men at work and five drills are running. At the 70-ft. level on vein No. 5 rich ore has been struck, indicating an extensive deposit. No. 8, at its junction with No. 5 at the surface, and also at the 70-ft. level, is showing up well. The ore at present blocked out will provide work for 12 months.

On the Cobalt Contact, in Bucke township, an 18-in. vein of silver and argentite has been discovered some 100 ft. from the main shaft. A depth of 10 ft. on this new vein has been reached and ore extracted running from 9,000 to 12,000 oz. per ton. At the Red Rock rich ore is being sacked from No. 1 extension, stated to assay over 10,000 oz. per ton.—A good strike is reported on the Anima-Nipissing property southeast of Latchford.—Development work is being actively carried on at the McKinley-Barragh, where all the plant for the concentrator has now been delivered. Work is being pushed on the Kendall vein where cross-cutting has been done for 100 ft. to an average depth of 15 ft. and a quantity of ore secured showing 12,000 oz. silver per ton. The vein also carries from 5 to 12% niccolite.

Some good finds of ore, showing visible gold and silver, have been made on the Crawford properties in Otto township near Boston station on the Temiskaming

& Northern Ontario Railway. A shaft has been sunk 25 ft. on a vein 3 ft. wide, containing galena, silver, and lead. A black schist formation at the side of the vein contains free gold. A lode of sugar quartz on one claim shows visible gold on the surface. A company capitalized at \$600,000 is being organized to develop the properties.—Willet G. Miller, Provincial Geologist of Ontario, accompanied by Noah Timmins, of Cobalt, has gone to inspect and report upon the new gold area in the Abitibi Lake district.

Shipments of Cobalt ore for the week ending August 10 amounted to 150 tons, from the following mines: Buffalo, 30; Nipissing, 32; Silver Queen, 88 tons of ore.

Denver, Colorado.

The Golden Cycle Mill.—Strike on Colorado Southern.—Coal Shortage.—The Western Federation.—Gold Prince Mines.

The unfortunate fire which almost completely destroyed the mill of the Golden Cycle Mining & Milling Co. at Colorado City on August 7 resulted in a loss to the company of over half a million dollars, about one-half of which is covered by insurance. Excepting the building containing the cyanide vats and the transformer house the entire plant was consumed, as well as a number of freight cars that were standing upon the siding. The fire is supposed to have started from an explosion of unburned gas within one of the Holthoff-Wethey roasting furnaces. The combination of an insufficient water supply and a strong wind from the northwest defied the efforts to subdue the fire and within two hours only the ashes of the plant remained. The plant, the largest and most modern cyanide mill in Colorado, has only been in operation for a few months. The site was originally occupied by the Telluride Reduction Co., which attempted unsuccessfully to put in operation a bromine extraction process. This company was taken over by the General Metals Co. of New York, which a short time later closed the plant permanently. The Golden Cycle Co. last year purchased the site and equipment, and three Holthoff-Wethey furnaces, which were the cause of the fire being the only important part of the original plant included in the new one. Four Edwards furnaces of 100 tons each were added, the sampling and crushing houses enlarged, and a grinding amalgamation and cyanide-house built, the sand being treated by percolation and the slime by agitation and slime-filtration on leaf-filters. Amalgamation proved unsatisfactory and blankets were substituted. The plant was designed and erected under the supervision of Philip Argall. The normal capacity was 800 tons per day and the treatment rates made by the company were so low that a large part of the tonnage of the Cripple Creek district was diverted to it when it began operations. The many mines that have dissolved their contracts with the smelters and other custom mills will either be obliged to close down or renew their contracts on the old terms. The result will probably be considerably to decrease the tonnage of the Cripple Creek district for the remainder of the year, especially of the low-grade ores.

The continuation of the strike of the employees of the Colorado & Southern is causing considerable embarrassment to the mining industry of that part of the State served by the road. Such mines as operate by electric power and are consequently independent of delays in coal supply are unable to get their concentrates moved and are obliged to suspend milling until the congestion is relieved. The smelters are the most handicapped by the shortage of coke, and it is stated that unless the strike is soon broken the Pueblo plant of the Colorado Fuel & Iron Co. will be obliged to blow out their furnaces, at a con-

siderable loss to the company. The efforts of the mediators who have gone to Washington have so far been unsuccessful, although the Commissioner of Labor, C. P. Neill, is engaged in negotiations with the president of the road and the Grand Master of the Brotherhood of Railway Trainmen. Fifteen coal mines in the vicinity of Trinidad have been obliged to close down on account of the shortage of cars. At Central City a dozen of the superintendents and managers of the local industries turned out and operated the trains to prevent a complete tie-up. The city of Denver will also be hampered in its gas supply unless relief is forthcoming soon.

Haywood has returned to Denver and resumed his duties as secretary of the Western Federation of Miners. Moyer has also returned and is at present in retirement. Senator Borah has been in conference with the Colorado authorities, and it is probable that Adams will be extradited to Colorado and there tried for the dastardly murder of A. L. Collins. Pettibone is to be tried at Boise at an early date. The expense of these trials constitutes a serious drain on the finances of the State of Idaho.

The Gold Prince mines near Animas Forks are being examined by the engineers of the Venture Corporation of London, with a view to purchase. If the deal is consummated it will add another to the list of large mines in Colorado owned and operated by English capital. The orebody in the workings of the Gold Prince is extremely large and is said to contain exceptionally rich shoots. The mill on the property has only lately been put in operation, and is unquestionably the largest and most modern stamp-mill in the State. Among the features of its construction are the steel frames and concrete foundations of the 100-stamp batteries and the use of Card tables to treat the fine product, the coarsest being treated on Wilfley tables, and the tailing then reground in tube-mills.

Leadville, Colorado.

The Railroad Strike.—Work on Rock Hill.—Successful Leasing Companies.—Testing With Churn-Drill.—The Old Crown Point.—Prospecting on Breece Hill.

An erroneous report to the effect that the card system will again be introduced in the Leadville district has gained wide circulation. This story is without foundation, is the unanimous reply of the members of the Mine Owners' Association.

The strike among the employees of the Colorado & Southern Railway seriously hampered the shipment of ore from any important mines on Fryer and Carbonate hills, since practically the only outlet for the products of these properties is by the high-line branch of that railway. On the other hand a coal famine was imminent, owing to the same cause. For nearly a year it has at times been impossible to obtain sufficient coal to meet the demands of mining operations, and whenever there is an interruption in the railroad service, it is only a question of a week or so for the stock of coal to become exhausted. The settlement of the strike was therefore most welcome locally.

At the present time Rock hill is most active in substantial exploration and development work. Many new shaft-houses are being erected and plants of greater or less importance installed. Within a year the trend and approximate position of several important ore-channels have been proved. The Rebate Mining Co., operating the Crescentia, is shipping 25 tons of lead sulphide daily and is opening up new ground which promises an increased supply. The shaft of the Ovens Leasing Co. on the Alhambra has reached the contact and driving is well under way to prospect the ore-bearing zone which A. F.

Wuensch, the manager, expects to prove productive.—Howard Collins has returned from the East after completing arrangements with investors to take over the Long & Derry mine. The property was formerly operated by the Anona Mining Co. and substantial gold returns were obtained from near the surface. An adit was started with a view to development of orebodies at a much lower level, but the adit was never completed, and it is the intention of the present company to drive this bore to cut the vein.—Operations on the Hoffer shaft have recently been discontinued on account of the unusual flow of water. Mr. Hoffer will install a larger pumping plant at once, when operations will again be resumed.

The shaft on the O'Donovan Rossa has reached a depth of 540 ft. and passed through a fault zone more or less filled with granite boulders and other extraneous rocks; Mr. Emmons has designated this as the Pendery fault and it is locally known as the Carbonate fault. When the 600-ft. point is reached, a drift will be driven to the

A Part of Colorado.

west across the fault to develop the ore-channel.—It is reported that the lessees of the Hopkins property on Mt. Sheridan have cut a vein of valuable lead-silver ore. This part of the district has been receiving more attention during the present season than at any time previously.

The work of driving the Dinero adit, which was begun early in April, is progressing satisfactorily as a result of the efficient power-plant equipment. The breast has passed the 1,000-ft. point and several veins of minor importance have been cut, but the important lode which prompted the enterprise will not be reached until late in the fall.—A large churn-drill has been in operation since August 5 on the Neusitz placer, in the vicinity of the Capital mine. From the information obtained during the sinking of the shaft on the latter, the wash will be found several hundred feet deep. The operations in the Capital shaft were discontinued owing to excessive water. The Neusitz Placer company will not attempt sinking until the work of prospecting with the drill has tested the ground.

The Crown Point is shipping more than 1,000 tons monthly of iron and lead ores under the lease of Nelson & Casey. They have carried the drift into the old workings

of J. D. Morrissey, where large bodies of low-grade sulphides were formerly developed, and which now can be mined at a profit. Conditions at the Mammoth continue favorable. Three prospect drifts are in ore. Although no shipments of importance have been made, this property will probably enter the list of shippers before the close of the present year.—One of the promising properties of Breece hill is the Sunday mine, which resumed operations nearly a year ago under lease to M. Nicholson. A steady tonnage of silicious ore is now assured.—The Silent Friend on Little Ellen hill has resumed shipments, which are principally lead carbonate containing silver. This property was opened during the early part of the year and lately has been equipped with a modern plant of hoisting machinery.

Johannesburg, Transvaal.

The Strike.—Old Tactics.—Dynamite Outrages.—Gloomy Condition of Affairs.—Gold Production Maintained.

I suppose it is a trait of human nature never to recognize defeat, even though it stare you in the face. At any rate this trait is very noticeable among the strikers on the Rand at the present time. They are hopelessly beaten, and yet they still hold meetings at which their unprincipled leaders tell them that they are on the eve of victory. Such a lot of short-sighted lie-loving leaders never took men more completely into a bog and left them there, than the men who engineered this strike. As usual the Australian agitator is very conspicuous. One of them, Outhwaite, a gentleman who never stays long in any one colony, came to the conclusion some weeks ago that the game was up, so he has gone to England to collect money for the Transvaal strike fund. His place was taken by an Australian equally as bad, one Wilson-Wilson, or 'Windy Wilson' as he is now called. Wilson and the Miners' Union made desperate attempts to get up a general strike along the Rand on July 4. The Government was warned that unless a Compulsory Arbitration Act were passed before that date, every artisan on the Rand would throw down his tools on that date. Botha acted with his usual skill, and pursued the Machiavelian policy of sympathizing with the strikers and at the same time of doubling the soldiers around Johannesburg to prevent them from getting on the war path. Well, the 4th of July, which was to be a 'workman's Day of Independence,' has come and gone, and the efforts of the strikers have failed completely. Scarcely any men that were at work threw down their tools on that day, and the mills ran merrily as if nothing had happened.

Seeing how complete their defeat is, the strikers out of revenge are resorting to dynamite. Already there have been a number of outrages, in which several lives were lost and a number of people were injured. Last week a small hotel, in which a number of 'black legs' were congregated, was dynamited, but strange to say no one was seriously injured. Two nights later, however, a hotel in Bocksburg was blown up, when two men were killed outright and a number injured. The strikers are not confining their attention to hotels. Several pumping stations have been wrecked and one shaft. The mines are now taking every precaution, and more watchmen have been put on to guard the properties. The strikers are also trying to strike terror into the community by writing threatening letters to a number of prominent men of Johannesburg, warning them to leave the city. These letters are treated with the contempt they deserve, the recipients preferring to die, rather than fly from an enemy so contemptible and so cowardly. The little sympathy the strikers once had from the public is withdrawn completely. Even Wilson, the Windy, is held in contempt,

especially as he has deserted the strikers, and gone to another centre to stir up strife. Another leader is leaving this week.

The commercial community is suffering severely from the effects of the strike. This war has accentuated the depression, and many firms are on the brink of ruin. The whole outlook is enough to dumbfound the most blattant optimist. One of the Labor members in the House at Pretoria, gave notice the other day that he intended bringing in a bill for compulsory arbitration for all future disputes. The strikers are indignant that the bill will not be retrospective. It is doubtful that a majority of the members will vote for a Compulsory Arbitration Act, seeing that the scheme has not proved a success in Australia, where the workmen applaud all decisions given in their favor, but consider the act iniquitous when the judges go against them.

In spite of the strike the results for June show up remarkably well, and prove that the effect of the labor troubles is insignificant. The total yield for June was 507,559 oz., valued at £2,155,976, showing a decrease of 16,918 oz., valued at £71,862 over May. There were

Map of the African Goldfields.

8,523 stamps at work in the Transvaal, of which 8,165 were crushing on the Rand and 358 in outside districts. During June 1,912 coolies were repatriated, and 1,882 Kaffirs went home, but the mines are trying to make up for this loss by demanding greater efficiency from the unskilled laborers who remain. The number of stamps at work does not change much, and the whole Transvaal industry seems to be standing still. No one has the courage to undertake the starting up of any new ventures. One mine, the Hercules, which is sinking a seven-compartment shaft, decided to cease work during the month.

Although it is indignantly denied by the strike committee, many of the strikers are returning to work, and are being taken on where there is room. Of course, the strike has dislocated the industry somewhat, especially as regards development work, the policy being to keep the mills at work. The achievement of keeping the mills at work in spite of the strike is a fine one, but it will take some time to get the mines into the position they were in before the outbreak of the strike.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

BASE, or lead bullion, is the term applied to the lead product of the lead smelting of gold and silver ores.

A CORRESPONDENT asks whether he can buy machinery and charge the cost up to assessment work on an unpatented mining claim. Reply is: Certainly not.

POTASSIUM nitrate is a powerful oxidizing agent and basic flux and is used in the assay of sulphide, arsenide, and telluride ores. It melts at about 350° and decomposes at a higher temperature, yielding oxygen, which oxidizes the sulphur and many of the metals. One gram of nitre will oxidize about four grams of lead.

As a general thing, jigs treating coarse stuff require more water than those treating fine material, because larger grains settle faster and because water can pass up in a small number of large interstitial spaces with much less friction than in a large number of small interstices, even though the total sectional area may be the same in both cases, and because large discharge orifices are required above and below.

A BREAKER that mixes two kinds of action in handling its charge will generally be found to be wasting either power or time by so doing. If a breaker crushes the coarser lumps in one part of the jaw by pressure and in another by a grinding action, either the pressure is better than the grinding or the grinding is better than the pressure, and whichever method proves best for that lump would be economical of power in treating all the lumps.

SOME millmen prefer the back knee frame for the stamp battery, because of the solid bracing to the ore-bin. The tappets are in plain sight, the pull of the belt is downward on the cam-shaft, and less lumber is required. If the ore-bin is flat-bottomed, the anchorage and bracing will be strengthened. An objection to this design is the fact that the line-shaft is subjected to dirt and is in an awkward position.

CYANOGEN is composed of carbon and nitrogen, both together forming a composition for which the chemical formula C_2N_2 is used, and which in its action is similar to one single element. The cyanides of sodium and potassium are combinations of these bases with cyanogen, the former acting as carriers for the cyanogen. The action of these compounds in the extraction of gold and silver from ores is based on the fact that they form with these precious metals soluble double compounds.

THE standard unit of the United States and British linear measure is the yard. It was intended to be the same for both nations, but in reality the standard in the United States exceeds that of the British by 0.00087 inch. The actual standard of length in this country is a brass scale 82 inches long, prepared for the Coast Survey and deposited in the U. S. treasury building at Washington. The yard is between the twenty-seventh and sixty-third inches of this scale, at a temperature of 62° Fahrenheit.

IN cleaning up the mortars and mercury traps of stamp-mills working on gold ore, much valuable amalgam is found mixed with quartz, iron, and other foreign matter. These remainders, upon being placed in the clean-up barrel, with additional quicksilver, and cast iron balls, are thoroughly ground and worked, the amalgam being

taken up by the quicksilver and separated from the waste matter. These barrels work intermittently, and are simply small ball-mills consisting of plain iron cylinders revolving on horizontal axes.

IN comparing the work of the Blake and Dodge types of jaw breakers, there seems to be but little doubt that the Dodge gives a higher percentage of fine than the Blake, with the same movement at the throat, especially when run at nearly full capacity or under the condition of choke feed. This may be accounted for by the fact that the Dodge is putting in more work at the mouth than is needed to prepare the lumps for the throat. The frequent choking or stopping of the Dodge is probably due to this excess of fine material, combined with the larger movement at the mouth.

IF, during the process of cupellation in the assay of an ore, the cupel contains the oxide of lead crystallized around the inside, it is said to be 'feathered.' When a cupel is feathered, the temperature has not been high enough to volatilize any of the silver. If the temperature in the muffle during the process of cupellation is too low, or the draft is too strong, the button will 'freeze,' becoming covered with a film of lead oxide that prevents further oxidation. They may be thawed by placing them in a hotter part of the muffle or by placing a piece of charcoal on top of the frozen cupel, but results obtained from thawed buttons are not reliable.

A LARGE variety of zircons is found in the gem gravels of the island of Ceylon, with many other precious stones that are a good deal confounded among native dealers and classified largely by color. The green variety is mostly zircon, with some tourmaline and chrysoberyl. The pale brown also includes some tourmaline. Other varieties of zircon found are rich yellow and fiery red. The readiness with which zircon alters in color by heat is illustrated by the fact that many greenish stones become a fine yellow by heating, and that the pale brown ones are often completely decolorized in the same manner to form the so-called Matara diamonds.

THE uses of chromite are many and varied. The chief use of high-class chromite is in the manufacture of soda and potash chromates and bichromates, which are used as the base for the manufacture of the various other chromium salts. It is also used in the manufacture of ferrochrome for the hardening of iron and steel, and for this purpose it is coming into more extensive use year by year. Besides their use in making chrome compounds, chromates and bichromates are extensively used as pigments in dyeing and printing. Another important process in which chrome is becoming widely used is that of chrome tanning, in which it replaces the tannin of the older bark process.

Two processes have been announced by German experimenters whereby it is claimed that minute crystals of diamonds have been obtained. By one of these it has been able to produce such crystals from pulverized carbon heated in hydrogen on a spiral of iron wire in the electric arc under a pressure of 3,100 atmospheres. The other is a process of fusing graphite with silicates. The experimenter prepares a mixture representing as nearly as possible the composition of the African blue ground, and then introduces powdered graphite. The whole is melted in a crucible, the process being facilitated by using metallic aluminum and magnesium in preference to the oxides of those metals. When the fused mass is dissolved, minute octahedra are found, possessing the physical properties of diamonds.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Mining Schools and Their Graduates.

The Editor:

Sir—The letter of comment from Mr. George E. Packard emphasizes some points that I touched upon in my communication of May 25. I think his criticism in regard to the State institutions is entirely fair, and it is a matter of common knowledge that the presidents of these schools are often retained because they are good organizers and know how to appeal to legislatures for appropriations, rather than from any acquaintance they may have with the mining business. The table showing the occupations of the graduates of the Lawrence Scientific School is interesting and illustrates the point that I tried to make in my previous communication. We find the men are superintendents, engineers, geologists, metallurgists, or teachers. Where are the foremen, shift-bosses, master mechanics, and construction bosses? I believe the majority of men who have operated mines will agree that a superintendent or manager may know his business, or he may not. None of the actual operating devolves directly upon him, so those below him have no chance to check up his work, and since he is responsible only to the directors, who sometimes know nothing of how a mine or mill should be run, he may get along well enough if he is a good office man and can put that end of the business on a systematic basis. Any man who is honest and has a general knowledge of bookkeeping and general business may qualify for the position of superintendent or manager if he provides himself with good foremen for the mine and mill, and no one need ever know that his operating knowledge is next to nothing, unless there are mining men among the directors, or a consulting engineer is employed. Manifestly this man cannot be as valuable as one who knows the details of the underground business and who is experienced in ore reduction. It might be mentioned right here that as a general thing superintendents and managers have a tendency to spend too little time underground and in the mill. They think that if they run the business end satisfactorily, they can leave the operating end to the foremen and shift-bosses. The inexperienced, of course, do this in self-defense, as they are strangers to the practical side and would not know whether things were being done right or not, even if they saw them. This isolation of the operating and business ends is a bad thing, but is quite unavoidable if the latter is in the hands of a man with little practical experience. An ideal superintendent should have an intimate knowledge of both ends and should be the connecting link between them. It is only under this condition that the maximum results can be accomplished with the greatest economy.

On the other hand, the foreman or shift-boss has got to know his business, because he is in constant and intimate contact with men that do know how. He should, and generally does, know more about how to do the work of each man under him than the man does. He should be able to turn his hand at a moment's notice to any job, and do it so well that it will serve as a useful example to the workman. If he makes a mistake or is lacking in skill or judgment, he is found out by his men, and his usefulness is at an end.

Several men have told me that it has been their experience that when they became superintendents the opportunities for learning the details of underground work

became limited. They could see how the work was going on, in their occasional rounds of the working places, but if they did not know how from previous actual experience, they could not learn by simple inspection, and were unable to appreciate the conditions under which the men were working or to intelligently criticize the results of their labor. Following out this idea, I have known men, who advanced rather too rapidly during the first years of their graduation, to go back to the manual labor end of the business, after several years spent in responsible positions, in order that they might become fortified with the self-assurance that only comes with intimate knowledge of detail. I remember a man who shortly after graduation was made manager of a property in Montana, through the influence of one of his relatives. He stayed with it two years, then resigned, and started in at the bottom, in another camp, giving as his reason the fact that he was unable to learn the details of actual mining while acting as manager. Business details demanded his presence in the office a good share of the time, and when he did get into the mine he could not talk with the men about their work with sufficient accuracy to avoid displaying to them his ignorance, and thereby losing their respect and courting insubordination. Even with his foremen he found it necessary to "look wise and say nothing," and had to be continually on the defensive. These features were especially prominent at the mine in question, as it was in a small isolated camp, where it was necessary that the manager be respected by everyone, if order was to be preserved. If this is a fair statement of conditions as operators find them, then it would seem to be best for mining engineers to spend at least the first three or four years after their graduation in gaining experience by doing manual work in several widely separated camps. Therefore, I say that the condition of affairs as shown by the table of graduates furnished by Mr. Packard may be considered rather deplorable.

Another question that comes up when we see so many superintendents on the list is: What are they superintending? For instance, at many little properties throughout Nevada, you will find a 'superintendent,' having entire charge of a hand-windlass and a crew of three or four men. To 'superintend' a property of this kind means the worst kind of mental and physical stagnation. Mr. Packard accuses me of exaggeration in the instances of reported and actual status. I can only say that the cases cited have come to my actual notice, and I know the details of each of them rather well, so there is no exaggeration. In fact, I might add a great many to the list by quoting other instances that I have seen at various places over a rather widely-scattered field. Perhaps Mr. Packard has not met with any such instances because he has not been close enough to the ground. As to the rest of my stand, of course, I have exaggerated. Everyone who writes or talks on one side of a question exaggerates a little in order to enforce his point. Mr. Packard's statement that the young graduates in engineering have done better during the first four years than the average young doctor or lawyer I consider entirely irrelevant, as these are notoriously professions in which the young man makes his start slowly, depending upon the future for his reward.

ONE OF THEM.

San Francisco, August 17.

THE SHIPMENTS of gold from Bluefields, Nicaragua, to the United States in 1906 were 41,990 oz., valued at \$533,636, against 28,413 oz., worth \$103,866, in 1905.

The Caving System at the Darien Mine.

Written for the MINING AND SCIENTIFIC PRESS
By A. B. CHASE.

The extraction of ore at the least expense is the paramount question at all mines; it was so at the Darien, near Cana, in Panama. This mine proved to be well adapted for the working of the caving system. The idea was first introduced in 1904 by Norris English, a young mining engineer of San Francisco, who at that time was acting manager for the Darien Gold Mining Co., Limited.

The system can be successfully worked on almost any vein, but it is at its best on wide lodes and large ore deposits. Every engineer knows how heavy is the expense of timbering and filling the average mine; if it were possible to abolish this expense and install the caving system, many of our low-grade enterprises could be made to yield dividends.

Under the old company's management the method of working had been based on the use of square sets, which

a round of 5-ft. holes was put into each side of the drift; from the same bar a round of 7-ft. 'uppers' was drilled; from the first round sufficient ore was removed to allow room to rig the bar for the second round, which consisted of 7-ft. uppers only, which broke through into the old workings of the 6th level, permitting waste to cover the ore as in the first case; likewise for the No. 2, 3, 4, 5, and 6 cross-cuts.

By drilling 5-ft. rounds on each side of the cross-cuts, the pillars were shot out, thus leaving the entire first floor a mass of broken material. In order to rig up and drill it was necessary to take out a certain amount of lode, in the operation of getting the ore into the chutes it was a greater convenience to use wheelbarrows than cars. While the work on this floor was being carried on, development was also in progress on the second floor, which was 14 ft. below. This distance was such that two 7-ft. rounds of uppers would break through into the old workings. The stoping on the second floor was the same as on the first floor. When breaking from the second to the first floor all the ore was taken until the waste started. The result of this method was that absolutely no ore was lost, and scarcely 5% of waste was milled. The filling was done from surface, as the lode had been extracted from the surface down to the 6th level. When the ore was extracted, the waste would settle, and it was necessary to keep the pit on the surface filled. The cost did not exceed ten cents per cubic yard; under the old system of filling, that is, of driving cross-cuts into the wall, the cost was nearly \$1.50 per cubic yard.

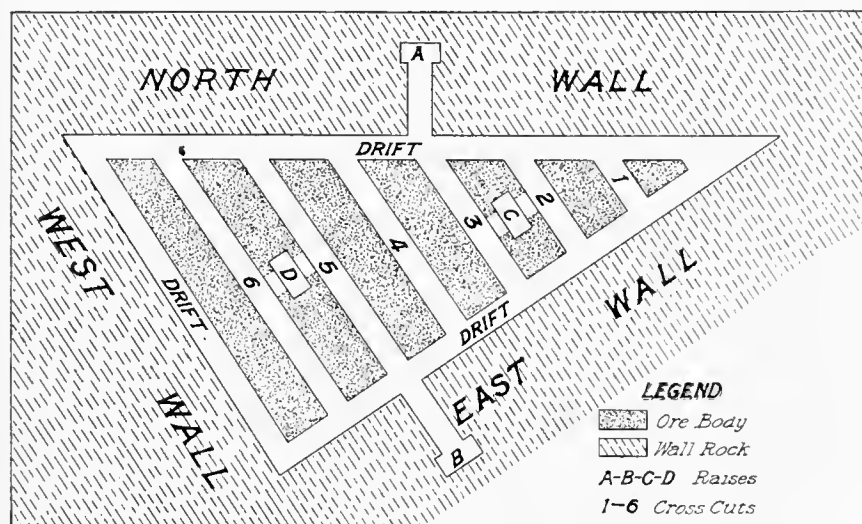

The positive gain as compared to filling is evident; furthermore, the method is a far greater security against accidents, as there is solid ground overhead, underneath, and on each side, with absolutely no expense for timbering.

There would in all probability be many variations in the system when used in other mines, owing to the character of the lode and the walls. Any suggestions or information will be gladly furnished by the writer, who was mine captain at the Darien during the working of this system.

There would in all probability be many variations in the system when used in other mines, owing to the character of the lode and the walls. Any suggestions or information will be gladly furnished by the writer, who was mine captain at the Darien during the working of this system.

GOLD PRODUCTION OF AUSTRALASIA.—The amount of gold mined in Australia and New Zealand for the first three months of 1907 was approximately 918,735 fine ounces, against 996,644 fine ounces for the corresponding period of last year, the value being about \$19,001,735, against \$20,613,034. The decrease in quantity is 77,909 oz., and in value about \$1,611,299. This decrease is a general one, Victoria being smaller by 28,830 oz., New South Wales by 4,855 oz., Queensland by 5,787 oz., Western Australia by 27,209 oz., and New Zealand by 21,880 ounces.

KLONDIKE DREDGING.—It is reported that the principal gold dredging company operating in the Yukon Territory will put three new dredges to work this summer on Bonanza creek. They cost \$225,000 each, erected ready for operation, and will be run by electrical power brought from a power-house 33 miles distant, and each machine is capable of handling 3,000 cu. yd. of earth per 24 hours. Another company is operating a dredge on the Klondike river with a capacity of 4,000 cu. yd. per day.

Plan of Darien Mine.

proved a great expense, and was wholly inefficient. The ore near the surface milled 2.35 oz. per ton. Any stuff milling less than one ounce was used as filling or left undisturbed. Below the 5th level the ore was of a decidedly lower grade, and it became absolutely necessary to adopt some means of extracting it at less expense.

The caving system was successfully applied in the following manner: The form of the orebody at the 6th level was a scalene triangle, having dimensions of 150 by 120 by 80 ft. From the 7th to the 6th level there were two raises in the country rock, one on the north wall and one on the south wall, keeping an average distance of about 15 ft. from the lode. There were also two raises in the ore. Fourteen feet below the 6th level drifts were run from the raises to the orebody. After encountering the ore, drifts were made along the east and south walls. Every 10 ft. cross-cuts were run through the lode to the north wall, these cross-cuts averaging 5 by 7 ft. On the north wall, 14 ft. below the 6th level, a drift was run the full length of the orebody. The cross-cuts from the east and south wall extended through to this drift, thus leaving the orebody entirely surrounded by drifts. Stoping was begun by cutting the mineral loose from the north wall through to the old workings on the 6th level. The ore from the first round of holes was removed; with the second round the old workings would be broken into, and the ore would be covered with waste. In cross-cut No. 1, near the north wall, a machine was rigged up and

The Uses of Indexes.

By ROSSITER W. RAYMOND.

[The following preface to the forthcoming complete analytical and alphabetical index of Vol. I to XXXV, inclusive, of the Transactions of the American Institute of Mining Engineers, here published in advance through the courtesy of the Secretary, will be interesting and suggestive to non-members, as well as to members, of that society.—Editor.]

The great additional value given to professional books by adequate alphabetical and analytical indexes has been recognized from the beginning in the publications of the Transactions of the American Institute of Mining Engineers. The first ten volumes, edited by Dr. Thomas M. Drown, as secretary, were provided with indexes, as well as tables of contents. Moreover, he included in Vol. V (published in 1877), a consolidated index of Vol. I to V, inclusive; and, at the time of his resignation in 1884, he had prepared a similar index of Vol. I to X, inclusive, which was published in the following year.

The indexes of the annual volumes from Vol. XI on were made much more extensive than their predecessors. Casual mentions, as well as important discussions, were included; the geographical localities of mines or works alluded to in the text were added in the index; and numerous cross-references were introduced, with the purpose of making it easy for the student to discover at once what the Transactions contained, either of thorough treatment or of hints and clues to further inquiry, concerning any topic, locality, or person within their scope. In order to extend the advantages of this larger scheme to the earlier volumes, a consolidated index of Vol. I to XV, inclusive (published in 1888), was prepared by compiling the several annual indexes, and introducing additional items for those preceding Vol. XI. Vol. XX, issued in 1892, contained a similar consolidated index for Vol. XVI to XX, inclusive; and in 1897, a separate index volume, covering Vol. XXI to XXV, inclusive, was published. These four indexes, for Vol. I to XV, XVI to XX, XXI to XXV, and XXVI to XXX, respectively, bound together into a book of about 950 octavo pages, have constituted for the last ten years a consolidated index to the Transactions which they cover—with the single difference that the book had to be consulted four times when a single comprehensive index would require to be consulted but once. This disadvantage, however, was relatively small, compared with the great convenience of finding by four trials in one book what would otherwise call for 30 separate searches in 30 books. Moreover, the possession of the one might be most useful to a student who did not possess the 30, by indicating to him what they contained, and thus enabling him to make further inquiry without fruitless labor. To this feature of value in such indexes, I shall presently recur.

The usefulness of the compound four-fold index referred to, is proved by the fact that the supply of copies has been exhausted. In view of this foreseen event, it was decided to issue, instead of the customary additional five-year index, a complete consolidated index of Vol. I to XXXV inclusive, which should take the place of all preceding ones; and Miss L. E. Howard, the accomplished and indefatigable librarian of the Institute, has been for more than two years engaged, with competent assistance, upon this laborious task. The result, embodying a compilation of the former index volumes and the annual indexes of Vol. XXXI to XXXV inclusive, with numerous corrections, improvements in classification, additional cross-references, etc., is the present book,

concerning which I desire to offer the following comments:

1. That this index is absolutely free from error, it would be ridiculous to assert. The atmosphere of an office and library crowded with daily visitors and overwhelmed with daily routine work does not permit such careful, intense, and minute revision as technical perfection requires. While many errors contained in our former indexes have been detected and corrected in this one, some have doubtless been brought forward into it. In this respect, I beg (though I hope it is unnecessary) to say, that with regard to this, as to every other, publication of the Institute, our rule and practice is, to be grateful, not annoyed, when we receive notice of an error, and to acknowledge and correct, not hide or ignore it. Notice of any errors discovered in this book is therefore earnestly requested.

2. It would be likewise unwarrantable to claim for the present index a complete and consistent logical arrangement. Indeed, I am disposed rather to assert for it a higher merit—namely, that of a method more elastic than any fixed system. The controlling purpose has been to make sure that the reader, seeking either the name of a mine or process, or the forgotten title of a paper or its author, or, on the other hand, desiring to be put upon the track of an inquiry concerning something which may or may not be mentioned in the Transactions, and wishing to be positively assured as to that point, before looking elsewhere, shall be satisfied as quickly as possible. Hence, in the construction of our index, we put ourselves in the reader's place, and often introduce a cross-reference not logically required by the text, because it may help him, if he has forgotten the term actually employed in the Transactions. In short, we make the index, not a mere concordance of words, but also a dictionary of topics and ideas. And, as to any proposed cross-reference, our rule is, "When in doubt, put it in!" For it cannot harm anybody, and it may help somebody.

The result of this system, if system it can be fairly called, has been, I know, that many members of the Institute have formed the habit of going first of all to the Index of our Transactions, sure of learning at once and without troublesome search, whether and to what extent, these volumes can aid them in any investigation they are called to make. I need not emphasize the folly of publishing, in these days, books on technical subjects without alphabetical indexes—a sin for which the most elaborate table of contents does not atone, and which, having repeatedly brought its own punishment, has well nigh gone out of fashion, as unprofitable sins are wont to do. But I may be permitted to express my surprise that so many editors and publishers of books intended for permanent reference, having taken the trouble to make indexes, do not take the small further trouble of making them adequately, abundantly—even unnecessarily and ostentatiously—full. There is no better recommendation of such a book to the potential purchaser, because there is no equal guaranty of its continued value to the actual purchaser. Practical men look to books for aid in the form of energy given or saved to them. Now mc^2 is the formula for energy; and in this case m is the information wanted, and c is the speed with which it can be obtained. In other words, m represents the value of the text of a book, and c the effective aid furnished by the index; so that the permanent usefulness of the book is represented by the text, multiplied by the square of the index! (mathematics, but it is unquestionable). This may be questionable experience, as the practice of nearly half a century qualifies me to declare.

3. Comparatively few of the members of this Institute

possess complete sets of its Transactions. The number of such complete sets now on hand is very small—perhaps 25. The volumes have never been stereotyped, and it is not likely that any of them will be reprinted. The Institute maintains at more than a hundred important mining centres throughout the world, free sets of its Transactions, open for consultation without fee, by all suitable applicants. This list cannot well be increased. If this new consolidated index of 35 volumes would be useful only to those who possess, or may hereafter possess, all of those volumes, the large cost of its preparation and publication would involve a most unwarranted and foolish outlay. I wish, therefore, to urge upon all students and practitioners, whether members of the Institute or not, the following considerations concerning the special value of this Index to those who have not the volumes themselves.

Indeed, in a certain sense, such an Index is more useful to the non-possessor than to the possessor of the books. For the latter can, at the cost of some extra labor, find out what each volume contains, whereas the former, having at hand neither books nor index, is utterly ignorant whether the Transactions could help him or not. I often receive letters from members thus situated, inquiring what our Transactions contain on this or that subject; and while I do my best to satisfy them, I cannot be sure that my hasty search is complete and conclusive; and I am obliged, whenever practicable, to refer them to some library containing the volumes, and bid them do their own hunting. But, on the contrary, if a member, finding in the Index the title of a paper, or the record of any remarks, concerning a subject in which he is interested, writes to the Secretary concerning it, I can easily, and always do gladly, tell him in reply what is the nature, length, etc., of the said passage; whether we can furnish it to him in separate pamphlet form, etc.—these being particulars which my clerks can ascertain for me at once. Moreover, members of the Institute send me, not infrequently, valuable professional papers, in which previous contributions to the Transactions, directly or indirectly dealing with the same subjects, are ignored. It is my theory that the author of an Institute paper should recognize what his fellow-members have done before him in the same line. Of course, if he fails to do this, it is because he does not possess the back-volumes of our Transactions, and is not acquainted with their contents. It is the duty of the Secretary to call his attention to this omission; and the result is not only extra labor for the Secretary, but often also some unnecessary mortification to the author, who is obliged to recast his paper in the light of the new information furnished to him. All this would be avoided, if the author had at hand simply an Index of the Transactions, upon the consultation of which he could have obtained from the Secretary, in advance, both guidance and aid.

4. But there is another and more important reason for recommending to all mining engineers, metallurgists, etc., whether members of the Institute or not, the acquisition of this volume. Namely, the issue of it by the Institute is part of a plan, the full realization of which is scarcely yet in sight, while every step towards its complete accomplishment is, in my judgment, to be regarded as an assential gain.

As is well-known, the generosity of Mr. Andrew Carnegie, for many years a member, and now an honorary member, of this Institute, has provided for this Institute, together with the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, the magnificent building in which our headquarters are now permanently located. One consequence of this arrangement is that the libraries of the three societies are

accommodated together in the 12th and 13th stories of the building. These libraries, aggregating more than 50,000 books, pamphlets, etc., comprise perhaps the most complete record of modern engineering practice in the departments of the three societies which can be found in the United States—for specifically American practice, perhaps the best in the world. At the present time, they are separately owned and administered by the three societies; but, so far as their use is concerned they constitute practically one library, to which the members of each society and others properly introduced, have free access. We hope, by means of indexes and catalogues, to extend this advantage to members at a distance, who may thus be enabled to consult books and periodicals by correspondence, to obtain copies of text and drawings, etc. Towards this end, the issue of the present Index is an important step.

A WOOD PRESERVATIVE.—Recent experiments in Belgium have been made with a new coal-tar extract, known as injectol, which have given satisfactory results. The experiments were principally devoted to the treatment of wooden poles and blocks used in street paving. The product is a liquid of a dark-brown color, thin, and of regular density. Its degree of viscosity changes but little with atmospheric variations. One of the principal advantages is its penetration into certain woods without any pressure. For the antiseptic treatment of compact woods, using the apparatus similar to the Breant system, the time necessary for the pressure and soaking into of a given quantify of injectol is considerably less than for any other antiseptic liquid, including creosote. As regards its antiseptic qualities, the following experiments and results obtained therefrom speak for themselves. It has been found that where creosoted poles in the ground have only resisted decay for a few months, those treated with injectol remained unattacked after three years. Similar experiments were also made with railway sleepers; the latter were treated with different antiseptics. Some were soaked in a mixture of coal creosote, creosote and chloride of zinc, and two were treated with injectol. After having been left for a period of two years in a steeping vat composed of liquid manure and other miscellaneous decomposing substances, it was found that the two treated with injectol were still in good condition while the others were almost completely destroyed. Similar results were obtained with wooden blocks for street paving. Other experiments are now being carried on and the results obtained will soon be made public.

AN interesting discovery of variscite, an attractive and wholly American gem stone, hitherto obtained from only one locality—at Mercur, Tooele county, Utah—was made in Utah. The situation is about 20 miles northwest of the old one, 9 miles west of Stockton, and some 40 miles southwest of Salt Lake City. The mineral appears in a vein that crosses a little spur or foothill running eastwardly from the main range of the Stansbury Mtn. The variscite occurs in two seams or veins which traverse this foothill in a northerly and southerly course, dipping steeply westward. The surface rock appears to be an iron-stained brecciated quartz. At the west end of the hill, where a little depression separates it from the main Stansbury range, there is an outcrop of brownish laminated quartzite; at the east end appears a strong body of bluish limestone. No metallic veins have been observed in the vicinity. The variscite itself occurs in the same manner here as at the Mercur locality, in roundish or kidney-shaped nodular masses, from the size of a lemon to that of a large cocoanut, with a rough external coating or casing of reddish-brown color, inclosing the beautiful green material within.

The Mines of El Doctor.

Written for the MINING AND SCIENTIFIC PRESS
By T. D. MURPHY.

These mines are in the northeastern part of Querétaro, about seven kilometres from the Montezuma river, which forms the boundary line between the States of Querétaro and Hidalgo. The nearest railway point is Bernal, on the main line of the Mexican National Railway, 80 km. from the mines. This station is 204 km. or 5½ hours by rail north of Mexico City; it is becoming an important

Laguna Reduction Works.

shipping and distributing point for the lead and antimony mines of the district.

Little has been written of the history or geology of this district. When the Spaniards spread over the country in their eager search for mines, they invaded the remote mountains of Querétaro as well as the more accessible parts. They discovered and worked the El Doctor mine and many others in the vicinity. Coming in by way of Zimapan, one of the oldest mining towns in Mexico, they discovered mines at Maconí, El Doctor, and San Cristóbal, and then spread northward to the important districts of Guanajuato, Zacatecas, and San Luis Potosí. The ores were transported to places where water was available, as is testified by the ruins of many old smelters and water-blowing towers, now crumbling to decay, but grass-grown slag dumps are found in the hills all over the country remote from the rivers, where smelting was carried on in stone and *adobe* furnaces, the blast being furnished by hand-blowing. They did close work too in those days, for the dumps are low in silver. To obtain air for the furnaces, water was conveyed in an aqueduct and dropped some distance through a stone shaft (*chiflón*). The entrained air, and that drawn through openings in the sides of the shaft, was compressed by the descent. A separation was effected at the bottom of the shaft, the air going through a main to the furnace and the water running back to the river. There is a record of the operations of some of these old smelters as far back as the year 1700. Previous to 1780, however, not much

is known of the history of the mines, but an account has been kept since then. During the revolutionary periods work languished, but between 1821 and 1878 operations were carried on with energy. No accurate data in regard to the production of the district from the time of discovery to the present date are available, but the total production is said to be \$40,000,000 in silver.

After the Spaniards left the country the mines came into the hands of Ignacio Trigueros, a Mexican, who did considerable work, but operations were soon suspended by him on account of the difficulties of extraction and unwatering, as everything had to be carried out on the backs of *peones*. After lying idle for several years, in 1884 Gustavo Beaurang, then consul-general of Belgium in Mexico, came into possession of the mines. He unwatered the workings, did some development, installed machinery and a water-jacketed smelter, and inaugurated a new era of mining and smelting; he was succeeded by his son, Victor. Young Beaurang had received a good technical training at a college in Belgium and had spent some time in practical work at various mines and smelters in Europe, and on arrival at El Doctor in 1886 he was well equipped to direct operations in the mining and metallurgy of lead-silver ores. Being shrewd and strenuous, he proved an economical manager, and many of the improvements he introduced at the mines have left

marks of his ingenuity. The business earned profits for a number of years, but hardly any of the money taken out was put back in underground development or betterment of the mines, being invested in other enter-

Loading Mules With Bullion for Germany.

prises in Mexico, consequently the properties were never opened up as they should have been.

When Beaurang entered the district he 'denounced' a large area of country surrounding the then producing mines in order to discourage possible rivals from coming in. This scheme worked well for a time, but the payment of taxes became a burden and he soon permitted many of the chief denouncements to lapse, thinking, perhaps, that the fact would not be discovered. He was eager to make money, but he disliked to spend a dollar if it could be avoided. Labor was cheap in those days,

because the Indians had never been disturbed by offers of higher wages to go to other mining camps. The important work about the mines, such as engineering and metallurgy, was done for little or nothing by young men from the colleges in Belgium and France for the sake of the experience gained. Many a thesis was written upon the subject of geological formations in the El Doctor district, with special reference to the Cretaceous fossils found there, while the young fellows were surveying in the mines or working a shift at the smelter; for Victor Beaurang never permitted his college chums to remain idle.

In 1900 Thomas Braniff Jr., of Mexico City, who was on a tour of inspection of the mining districts of Hidalgo and Querétaro, with an eye to investment, rode across the range from Zimapan to Maconí. After a personal examination of the old workings, and the mines in operation at that time, he became impressed with the future possibilities of the district and made up his mind to invest. Returning home he sent out Fernando Vivanco, an energetic young engineer, who proceeded to acquire extensive holdings in the Maconí district for Messrs. Oscar & Thomas Braniff. He denounced a large area, and in doing so discovered that Beaurang had no title to many of the properties claimed by him, so Vivanco properly took possession of the lapsed claims for his own people. During the following two or three years he did a good deal of exploratory work, principally in what is now known as the La Negra mine.

During 1904 the United Mining & Development Company of America, a New York corporation, took an option on the Maconí group of mines, and spent some money in building roads and other work. After a year or so this company withdrew from the district, but not because they were dissatisfied with the mining prospects. About this time Victor Beaurang died, and Messrs. O. & T. Braniff purchased from his estate its entire holdings in the district, comprising the El Doctor, Valenciana, Santo Entierro, and many other mines, consolidating them with their own. Thus they came into undisputed possession of every mine of any consequence in the district, with absolute title from the Federal Government, and they are still the owners. In March, 1906, I was engaged by the Messrs. Braniff to take charge of the mines, effect a reorganization of the local forces, and place the mines and smelters in such condition that profitable operations might result.

Taking the district as a whole the geological conditions are not complicated. A great belt of crystalline magnesian limestone crosses the country above beds of shale and limestone, of Cretaceous age. Where dikes intrude, the limestones when pure have been altered to crystalline marble, or when impure, to a garnetiferous rock, for a considerable distance from the dikes. During upheaval, especially near the dikes, there has been folding, and even re-folding, so that the younger series of strata are found below the older. An abundance of Cretaceous fossils exist, chiefly in the marbleized limestone, although some have also been observed in the lime-shale. A few marine shells have been picked up on the surface of the ground.

Sedimentary strata, iron-stained mountain slopes, prominent dikes, and high marble cliffs are the distinguishing geological features of the district.

It is said that the El Doctor mines were discovered and worked by the Spaniards soon after the conquest, but it is thought by some that they may have been worked by the Chichimeca, or Otomi Indians, because near at hand on top of a large flat mountain, accessible from one point only, are the ruins of what appears to have been a large fortified city. The walls are of great length, and still of considerable height, built of roughly-shaped

slabs and blocks of lime-shale and limestone. There must have been a large population there at some time and it is possible they were engaged in working the mines. It is said that the El Doctor vein was discovered accidentally by some Indians who built a fire on the outcrop, thereby fusing the lead and silver. The principal ore-shoot has been worked almost continuously from grass-roots to a vertical depth of 500 metres, with a maximum length of 13 m. and the ore was of good grade all the way. When the old miners reached a vertical depth of 250 m., the difficulties of extraction, unwatering, and ventilation, became so great that they were obliged to go across the ridge and start a cross-cut adit, the present Socavón, to strike the ore-shoot. This adit was driven in small section for a distance of 883 m. The ore was cut and operations were carried down until the conditions again became too difficult and the work dragged along and was finally suspended for a number of years until Beaurang arrived on the scene. This adit has a single track, is fairly straight, of good size and grade, and is lighted with incandescent lights. An old roadway, or *galera*, to the outcrop is kept open as a means of ventilation for the lower workings, now 250 m. vertically below the adit. Near the face of the adit an incline has been sunk; overhead a chamber has been cut out in which is installed an electric-driven friction-drum hoist, operating a skip, with a capacity of about a metric ton (2,204.6 lb.) of ore per trip.

The geological formation is similar to the rest of the district, but while there is abundant evidence of intense metamorphism, there is a total absence of eruptive rocks or dikes, as elsewhere. At the upper contact, between the limestone and shale, the former has been highly crystallized, but is not garnetiferous. This gray and white marble reaches the surface, and forms great white cliffs along the outcrop of the vein. Geological conditions in the mine are fairly uniform, however, and there are not many signs of disturbance after the ore was formed.

The ore-shoots follow strong fractures in the sedimentary strata, occurring in a contact-vein between the underlying unaltered blue limestone and overlying lime-shale, that passes into a calcareous slate with depth; but the largest deposits and best ore are found between the shale hanging and upper crystalline limestone, or coarse-grained marble. In places the lode is entirely within the marble, and has the appearance of a fissure-vein, elsewhere it is made up of a net-work of lime and calcite streaks with ore between. The swells in the marble near the contact always contain the largest deposits. Sulphide ore also enters the shale and slate in the shape of pipes or tubes. Isolated irregular orebodies are also found filling cavities in the blue limestone, and are traced by means of small stringers leading away from the regular deposits. Large bunches of calcite are encountered, and near these usually occur deposits of carbonate ore of good grade.

The mine has always been worked in early Mexican fashion, following the ore, and as the shoots were persistent in depth they simply went down on them and did not explore along the strike to look for more. When the shoots begin to thin out toward the edges work is stopped. Practically all of the ore-breaking is done by *busecones*, and when the vein is reduced to half a metre in width the *barreteros* (drillers) will not follow it any longer unless it is rich, so that in reality the boundaries of the ore-shoots are not ascertained yet, because many faces exist where the ore is either narrow or low-grade, and it has often been found that the ore will open out from half a metre to two or three metres within a few metres of driving, with a corresponding increase in rich-

ness. Between the ore-shoots (in the direction of the strike) is a zone of lode-matter or ferruginous clay, containing a high percentage of iron and alumina, with from 250 to 500 grams of silver. This material is tightly packed and no doubt prevented the ore-bearing solutions from penetrating, the ore becoming concentrated along the larger fractures or watercourses where the rock was more open.

The average width of the ore is about six feet. The gangue minerals consist of calcite, quartz, dolomite,

Cake of Silver From the Cupel in Refinery. 124½ Kilograms.

gypsum, and calamine, native silver occurring in vugs of the last. There is a great quantity of iron oxide in the vein-filling. In places the ore is hard and dense; in others, especially in the ducts between orebodies, a large amount of low-grade vein-matter may exist with only a pay-streak on the foot-wall side that is soft and friable. The compact ore is always the best. The walls are often smooth and slickensided, showing native silver in sheets more than an inch square on the smooth faces. Where this occurs the ore is of good grade and will average six to seven kilograms in silver for a distance of six inches or so from the streak of native silver. The general average of the ore brought to the surface is about one kilogram (32.15 oz. Troy) of silver per metric ton. The ore does not contain much lead, the average being about 1½%; the other components are iron and copper pyrites, some zinc blende, antimony, and arsenic, most of the silver being with the iron pyrite and gangue. It is aimed to extract as little ore as possible under a kilo in silver, therefore care is exercised underground in breaking and sorting as far as the light will permit.

Ventilation is poor, candles will not burn, and petroleum lamps are used. Often the flow of carbonic acid gas is so strong that the men are driven out of the workings for several hours, and at such times quicklime is introduced to absorb the gas. After this is slacked and exhausted it is gathered up and used for building walls and pillars. The Company pays P2.50 per metric ton for kilo ore in the mine, with a deduction of 15% of the weight for waste and moisture in the *patio*, the miner furnishing his own light and explosives, but the Company furnishes sharpened tools and moves the ore. As there are a number of individual contractors, much sampling and assaying of the various lots of ore has to be done, and in general careful supervision is necessary,

because the *buscones* are tricky. Nothing can be accomplished with the natives by day's pay, and if they are given explosives they are either extravagant in their use or will endeavor to carry them out of the mine to be traded for *pulque* or reserved for feast-days. On the other hand when they are obliged to furnish their own explosives, they will do little drilling or blasting, and will chip at the ore with *cunas* (gads), resulting in the production of an excess of fine for the smelters. Good ore must be found for the *buscones* or they will not work. Where development is in ore it has been found best to pay the men a small price per metre of advance and pay them at the regular rate for the ore broken, otherwise they will shoot ore and waste together or assist their friends working close by to annex the ore to their own piles, to the detriment of the Company. The price paid per metre of development varies from P12 to 15, the latter price being paid for winze or shaft-sinking.

Mining methods are crude as yet and partake of the nature of primitive Mexican mining, following the ore regardless of level. The ore is carried from the stopes to the shaft on the backs of *peones*, who average about five *arrobas* (126.76 lb. Avoird.) per trip, or 120 *arrobas* (3,012.35 lb.) per shift. The men earn from 60 to 75 centavos per day and the small boys about 45 cv. The *buscones* earn from 50 cv. to P1 per day, which is about the average in ore or development work. The *peones* rarely work more than five days per week and neither do the *barreteros*. If the latter are lucky and make a little extra money on their contract during the week it means that they will work a less number of days during the following week.

The ore from the stopes is dumped into chutes, let into the hanging wall of the shaft, and the skip is filled

Old Spanish Blowing-Tower at Maconi.

directly from these. Hardly any low-grade ore is taken from the mine; it is left behind as filling in the stopes in the form of walls, or pillars to support the roof, so there is a large tonnage of low-grade ore that can be concentrated for the smelter. No dumps of low-grade ore are found on the surface as in other old mining camps in Mexico. Not much timbering is done except for chutes and stulls. Timber is put in green usually and does not last long. During the rainy season water seeps through the rocks and gas is liberated from the lime and shale. Incandescent lights are used at points where the gas is strong. The problem of ventilation will have to receive serious attention before long.

It is difficult to maintain a uniform production from the mine on account of the irregular labor supply. When labor is fairly plentiful and the production normal, the cost per ton of ore placed in the *patio*, including ore-breaking, development, timbering, carrying and tramming, and hoisting, amounts to an average of P6.50 per ton. The ore is run out from the mine in cars and dumped over sorting screens into the ore-shed close to the mouth of the adit. Three sizes are obtained, *gabarro*, from egg size to large pieces as they come from the mine, *granzon*, down to nut size, and *arenilla*, the fine. The *gabarro* is broken by hand to suitable size for the smelter, sorted, and if oxidized is dumped with the *granzon* directly into the storage-bins alongside. The sulphide is trammed to the roasting-yards where most of the sulphur, with some zinc and antimony, are driven off by heap-roasting. The sulphide fine is made into bricks by hand with the addition of milk-of-lime and charcoal screening and roasted in circular stone furnaces. Owing to the small amount of lead in the El Doctor ores, the ores are carefully bedded in order to obtain a good smelting mixture. The ore-bed (*revoltura*) is formed of successive layers (*capas*) of oxidized ore, roasted sulphide ore, fine, matte, wall accretions from the blast-furnace, and by-products from the refinery. It is aimed to have about 10% lead in the completed bed, therefore a sample is taken of each layer and assays made so that no lead will be wasted. The silver is brought up to a kilo and over. Each bed contains about 350 metric tons, and in drawing off the mixture for the smelter a vertical face is maintained and the material is intimately mixed with shovels before charging. The ore contains sufficient silica, but lime and iron must be added. The lime is blasted from a quarry close to the smelter and is broken by native women to suitable size. When smelting operations are increased a rock-breaker can be installed at the quarry. The cost of limestone is 75 cv. per metric ton at the charging floor, but it is barren of silver. The iron is packed some distance by mule-back from a large deposit. It is of good quality and contains from 80 to 150 gm. silver per ton. The cost delivered is about five pesos per ton.

The smelting plant is a 36 by 42-in. water-jacket furnace with a capacity of 40 tons per day of all material. The blast for this furnace is supplied by a No. 4½ Baker blower, driven by a 15-hp. Westinghouse motor, and the average of the blast-pressure is from 12 to 14 oz. The furnace produces from 1½ to 2 tons per day of base bullion and about 1½ tons of matte. The base bullion averages 8 kg. silver, 6 gm. gold, 33% antimony, and 62% lead per ton, and the matte averages from 10 to 12% lead and over a kilo in silver. When the slag cones are cool the matte is knocked off, broken up, and roasted in heaps, to be returned to the ore-beds. The base bullion is ladled from a small well on the outside of the crucible into 20 kg. molds, sampled, and assayed, and either refined at the works or shipped to Germany. During the past year practically all of the base bullion produced was shipped, especially that from the El Doctor mine, because it is high in antimony, and the German people pay for the antimony concentrated in the bullion at the price of lead, and in the local refinery almost all of the antimony is lost.

The refinery is an old fashioned type of German cupel-furnace and is not economical, for several reasons. A poor quality of wood costs seven pesos per cord and has to be packed a long distance, and men and mules cannot be spared for this work. Half a cord of wood is required per ton of lead refined. A new cupel is necessary for each operation, and material for this has to be transported for some distance, and besides there is the cost of labor for shaping the cupel and afterward breaking it to get at

the absorbed silver and lead. Some silver is always left behind in the litharge, but of course this and the cupel material are afterward put into the ore-beds. Later on, when the production is greater, some one of the desilverizing processes will be found more economical. The recovery in the present refinery is an average of 95% silver and 85% of the lead, with the antimony almost a total loss. From 30 to 35 tons of lead bars form a charge and the run lasts for about seven days. A No. 3 Baker blower, driven by a 5-hp. Westinghouse motor, furnishes the blast for the cupel. The resulting cake of silver is extracted after cooling, broken into small pieces, melted in crucibles heated with coke and charcoal, and cast into bars, the silver averaging 998 fine. The bars are sent under escort to the railway and shipped by express to the mint at Mexico City. It has been found that although freight and treatment charges to Germany are high, aggregating P100 per ton of lead, it is more economical to ship than to refine, and no more refining is done than is necessary to furnish litharge for the *revolturas*. The lead bars are shipped by mule-back to Las Tucas, thence by wagon to Bernal, and from there to Tampico, where the bars are embarked for Germany. Each pack-mule carries an average weight of 140 kg. (308.64 lb.), and about 100 mules are employed. Mule and wagon freight amounts to P15 per ton, and railway freight to Tampico about the same. In addition to this the State and Federal tax on the silver exported has to be paid. Treatment charges are high, but a reduction has been promised.

The fuel used in the blast-furnace is a mixture of charcoal and coke, the latter from Baroteran, in Coahuila; about 12% by weight of the charcoal is used, but this varies according to the stock of the latter on hand. Coke costs P43.50 at the mine and is of fair grade. The total fuel used amounts to 20% of the charge, meaning the total ore and flux, exclusive of fuel and returned slag. During dry weather, when fodder is scarce, or during the rainy season when the roads are in bad condition, and the pack animals cannot work, more coke is used, and it is held in reserve to meet these emergencies. Charcoal is packed to the smelter from the mountains by mules and burros, probably more than a hundred being employed for this purpose, and P12 per ton delivered is paid. The Indians burn the charcoal in crude beehive ovens in the mountains. A central deposit is selected and the charcoal is carried in small lots to this point. An Indian will carry five *arrobas* (126.76 lb.) per trip and make several trips per day for long distances.

The average slag composition from the smelter is as follows: SiO₂ 33%, FeO 28%, CaO 23%, ZnO 2.5%, Al₂O₃ 10%, Pb 0.5%, Ag 60 gm. The last is considered too high, but it is a difficult matter to lower it economically. The furnace is fairly free from accretions, the campaigns are of good length, and an excess of flue-dust or fume is not formed. Taking all of the conditions into consideration, especially the size of the furnace, men qualified to judge have pronounced the work not unsatisfactory. The furnace is operated entirely with native help, and as they have had experience in the work from boyhood they are fairly proficient, but they are careless and have to be constantly watched or they will allow the jackets to burn, especially during the night shift. Charging, handling of slag and matte, and all other work in connection with the smelter, is done by hand, with inefficient labor. The average cost per ton of ore smelted, which includes breaking and sorting of the ore in the *patio*, tramping to roasting heaps and back to charging bins, roasting ore, matte, and fine, forming the ore-beds, fuel, flux, and supplies, amounts to ten pesos.

Common labor is cheap, but scarce and erratic. Each family of Indians has a small piece of land where they

grow enough corn to supply their actual wants; besides this they have a small herd of goats, and they only work in the mines to get money for luxuries. From October to February the *peones* will not work at all, and in May and June they are sowing corn. They are peaceable, but stupid and lazy, and as simple-minded as children, leaving their work on the slightest pretext. It requires patience and tact to manage them. The miners and *peones* are intemperate and observe all holidays, which are numerous, more for the purpose of loafing and drinking than respect for the day. When they are flush, from Saturday night to Sunday afternoon, their object is to eat, drink, and be merry, and when 'broke' during the balance of the week, they are hungry and wretched. They are like a large family bound together by one common purpose, which is to get something for nothing from the Company. They like amusement and welcome every occasion when they can congregate to dance and drink. A curious thing is the great distance they are able to shout from hut to hut in the mountains. The men talk business and the women gossip over almost incredible distances, and riding along the trails on a quiet morning it is interesting to hear them. On the Montezuma river there is a settlement of Otomies. They do not speak a word of Spanish, nor will they accept money or have any dealings with other Indians or outsiders.

Several things at present militate against low costs in the district, such as distance from railway, high cost of transportation and supplies, scarce and inefficient labor, irregular production, and antiquated methods that it is not feasible to change at present. In spite of these drawbacks the business is profitable, and, as many of the foregoing problems are likely to be solved, the future is bright.

The Stock Market.

Hayden, Stone & Co., of New York and Boston, make the following interesting comment on the financial situation:

There is no situation which calls more imperatively for calm, level-headed judgment than that occasioned by such an upheaval as we have seen this week. With speculative sentiment universally bearish there is grave danger of losing one's head and joining too enthusiastically in a movement which may be nearing its end. There are one or two things which are apt to be lost sight of at such a time as the present, and which it will do no harm to recall.

From all quarters not under the immediate influence of market sentiment still come reports of great prosperity. A little slowing down there has been which will in all probability go still further, but this has already been discounted. Crops, which are really the underlying factor of our prosperity, will have an average yield, and bring better than average prices; railroad earnings are still gaining, and net income, for the first time in months, is showing an appreciable increase. In other words, all factors governing intrinsic value of securities must be pronounced favorable, except the money situation.

Here we still continue to think lies the keynote to the situation, and here there is great menace. Several large underwriting payments are falling due, and the necessary provision for these, in conjunction with the already severe tension in the money market, would alone be enough to occasion a very severe break. On top of this has come strongly displayed animosity toward corporations in the Southern States. This, however, we believe is a factor which will soon come to a head, and will pass away. The people, after all, cannot do without the cor-

porations, and to cripple them would be only hitting one's nose to spite one's face. Nothing is so fickle as popular sentiment on this point, and a few more level-headed acts like that of the Governor of New York in vetoing the two-cent rate bill, would soon send the pendulum swinging the other way.

In the meantime, advantage is being taken of all the unfavorable factors to frighten holders of securities into selling them and investors from purchasing them, so that the buying to date has come very largely from covering of shorts, and as yet there is no organized support. We do not take much stock in the rumor that the Standard Oil crowd are selling securities in retaliation for the fine imposed on that company. The men behind this company would not be so short-sighted as to sell the old line issues at the lowest figures they have reached in 10 years. We are more inclined to believe that this and the attack on the Southern Railway are being used as weapons by the short interest to hammer the market and to bring out, if possible, long stock.

Boston has naturally followed New York's lead, and with no end in sight to the deadlock in the metal market, has sold copper stocks freely. Announcement is made this week of an assessment on Winona. This is rather a small company and the assessment is of little importance except as showing a tendency which is likely to be followed by others, beginning with the weaker companies, particularly with those who reopened their mines on the prospect of continued high copper; later on will come reductions in the rates of disbursements on the part of some of the dividend-paying companies. On looking back to the prices of the fall of 1906, when copper sold at 16c. per pound, and dividend rates were very much below what they are now, we find that prices averaged higher, so it is a question whether even the copper stocks, as well as the railroads, have not now pretty well discounted unfavorable contingencies.

Our summary of the situation would be that the man with money who can afford to pay outright for what he purchases will make no mistake in beginning to buy now, as the two unfavorable factors—tight money and corporation baiting—should gradually disappear in the next six months or a year. Those not in a position to do their own financing will find little to be gained by entering the market at present, as money conditions are such that it would be neither to their nor to their broker's advantage to carry their stocks, while those disposed to come in on the bearish side may perhaps reap temporary profits but should be prepared quickly to run to cover.

THE permeability or flow of water through concrete is less as the percentage of cement is increased, and in a much larger inverse ratio. The permeability is less as the maximum size of the stone is greater. Concrete with maximum size stone of 2½-in. diam. is, in general, less permeable than that with 1-in. maximum diameter stone, and this is less permeable than that with ½-in. stone. Concrete of cement, sand, and gravel is less permeable than concrete of cement, screening, and broken stone; that is, for equal permeability, a slightly smaller quantity of cement is required with rounded aggregates like gravel than with sharp aggregates like broken stone. Concrete of mixed broken stone, sand, and cement is more permeable than similar concrete of broken stone, screenings, and cement; that is, for watertightness, less cement is required with rounded sand and gravel than with broken stone and screenings. The permeability decreases materially with age; increases nearly uniformly with the increase in pressure; and increases as the thickness of the concrete decreases, but in a much larger inverse ratio.

Electric Heat v. Heat From Fuel.

The current issue of the *Electrochemical and Metallurgical Industry* has this to say on the above subject:

In our present issue we notice the last reports of our San Francisco contemporary, the MINING AND SCIENTIFIC PRESS, on the progress of the Noble Electric Steel Co.'s work at Héroult-on-the-Pit, in Shasta county, Cal. As will be remembered from our former notices this undertaking of Mr. H. H. Noble is noteworthy in two respects from an industrial point of view. If successful it will mark the beginning of the commercial manufacture of pig iron on the Pacific Coast, and at the same time it is the first commercial plant in the world in which the electric furnace enters into competition with the blast furnace. A concise analysis of the possibilities of electric heat versus heat from fuel seems timely, and it seems proper to first view the problem from the narrow point of view which is most unfavorable to the electric furnace and which simply inquires as to those relative costs of fuel and electrical energy for which the cost of the blast-furnace and of the electric-furnace treatments becomes the same. The immense importance of the element carbon in metallurgy is due to its double application as a strong reducing agent and as a fuel to produce, by its oxidation, the heat needed for the chemical reaction. In the case of reduction of iron from the ore, the blast furnace and the electric furnace require the same quantity of carbon to act as reducing agent and to combine with the oxygen in the iron oxide. But the blast furnace also requires carbon for producing the necessary high temperature, and it is only this last portion of carbon, the calorific value of which is replaced by electrical energy in the electric furnace. We will, therefore, first compare the cost of fuel and electrical energy to produce the same number of heat units.

One kilowatt-hour is equivalent to 860 kilogram-calories, which is approximately the full heat obtained from 100 grams of good coal when completely burnt to carbon dioxide. If the cost of a ton of coal of 2,000 pounds (or 907 kilograms) is a dollars, and if the efficiency of heat production by burning coal is x per cent, then the coal required for producing 860 kilogram-calories costs $a \div 90.7 x$ dollars. On the other hand, if the cost of 1 kilowatt-hour is b cents, and if the efficiency of producing heat from electrical energy is y per cent, then the kilowatt-hours, required for producing 860 kilogram-calories, cost $b \div y$ dollars. Hence electrical heat will be cheaper than heat produced by combustion of fuel if $a y$ is greater than $90.7 b x$. To go further, we need the efficiency figures x and y . By assuming definite figures we introduce, of course, an uncertainty into our comparison, but it will probably be considered fair if for a first approximation we assume a 25% efficiency for fuel heating and a 75% efficiency for the electric furnace. Then we conclude that electrical heat will be cheaper than heat produced from fuel if a is greater than $30.2 b$, or in words, if the cost of a ton of coal in dollars is more than 30 times the cost of a kilowatt-hour in cents. For instance, to compete with coal at \$6 per ton, the electric kilowatt-hour would have to cost less than 0.2 cent. This is clear evidence that if the electric furnace did not have other important features it could not compete with fuel heat under ordinary conditions.

We have purposely made this comparison on the basis of the cost of the ton of coal and of the kilowatt-hour, although it has become customary to use the electric horsepower-year as the unit of electrical energy in such estimates. Then the above condition can be stated in this way: Electric heat will be cheaper than fuel heat if

the cost of one ton of coal is more than one-half the cost of the electric horsepower year. Stated in this form, the comparison looks more favorable for the electric furnace than stated, as in the preceding paragraph. But in reality it is not proper to make the comparison on the basis of the horsepower-year, since we thereby implicitly assume that the electric furnace is working continuously every hour all year around, which is in general a decidedly improper assumption.

It is, of course, clear that the above comparison is exceedingly narrow in that it considers only one single side of the problem, namely, the amount of fuel and electrical energy required to produce the same number of calories. But even in this very respect the above comparison falls short of the truth and does not do justice to the electric furnace. The chief reason is that electrical heating is essentially internal heating, permitting a very high concentration of energy at any point wanted and thus enabling one to produce high temperatures. Fuel heating, on the other hand, is always more or less transmission of heat from the fuel to the charge, and the rate of heat transmission depends on the difference of the two temperatures; this rate decreases rapidly the higher we go up in the temperature. Naturally, with fuel heating we can never obtain any higher temperature than that of the burning fuel itself. There is no corresponding limitation in electric heating. This is the fundamental reason why for all very high temperature processes the electric furnace reigns supreme. This is an established fact, but since electric reduction of iron ore does not fall into this class of processes, we may not further discuss them here, except by pointing out that the possibility of obtaining higher temperatures might be found useful for special cases of iron ores; for instance, with titaniferous slags. It is of greater importance perhaps to refer to the fact established at the Sault Ste. Marie experiments that iron ores containing a high sulphur content can be successfully smelted in the electric furnace so as to get a pig iron containing only a few thousandths of one per cent of sulphur. Through the electric furnace certain iron ores will therefore become available for the production of pig iron which heretofore could not be treated economically. This will probably become more important in future years than it seems to be at present.

But there is another point. With respect to the reducing agent it was stated above that the same amount of carbon as reducing agent is required in the electric furnace as in the blast furnace to rob a certain amount of iron oxide of its oxygen. This is perfectly true, but it would be absolutely wrong to conclude that the electric furnace has therefore no advantage in this respect over the blast furnace. The point is that the blast furnace requires coke, while charcoal or peat coke will do very well in the electric furnace. This point is at the bottom of the whole situation in California. On account of coke not being available, California has not had its own pig iron industry. At the new plant on the Pit river there is unlimited timber for charcoal making. Viewed from every point the undertaking of Mr. Noble looks promising, especially if we consider that pig iron sells in San Francisco at about \$10 more than in Pittsburg. Let us hope that the work which was officially inaugurated on our national holiday, the Fourth of July, will turn out commercially successful. It would be a matter of great industrial importance for California and would stimulate similar progressive work in other districts where the conditions appear sufficiently favorable for electric smelting and sufficiently different from the conditions in our present blast-furnace centres. In the latter centres electric smelting for reduction of iron from ore is, of course, out of the question.

Oil in the State of Vera Cruz.

Written for the MINING AND SCIENTIFIC PRESS
By EZEQUIEL ORDOÑEZ.

In an article published in the 'Memorias de la Sociedad Alzate,' I explained the geological conditions prevailing in the Gulf-coast lands of Mexico near Tampico, Tamaulipas, in 22° latitude. These geological conditions were discussed in connection with the presence of heavy asphaltic oil found there in extensive seepages distributed all along the coast. The oil finds its way up through a uniform formation of shale of unknown age and more than 4,000 ft. thick. On account of the uniformity of constitution and the slight importance of stratigraphic accidents due to tectonic agencies, the strata are almost horizontal, with gentle undulations and low domes, similar in shape to the mounds of Texas,

carries a sandy material, consisting of small sharp pieces of shale, fine lapilli, and volcanic sand. This shows that the material referred to comes from the places where the oil is accumulated around the volcanic pipes, at a greater or less depth. Such regions impregnated with oil surrounding the solid or tufaceous core, are really in some cases the zones of friction caused by the upward movement of the lava, sufficiently cooled to rise as a solid body and to find its way to the surface, like the obelisk of Mont Pelé. In the tufaceous cones the oil contains fragmentary volcanic material that has fallen back into the chimney during explosive eruption. The more productive wells come, of course, at the base of the cones of this kind, by reason of the permeability of such material as has been shown in the wells drilled at the base of the Cerro de la Pez in the El Ebano oilfields, the *cerro* being composed of tufa. The Mexican Petroleum Co.

although not, of course, of the same origin. The impervious condition of the shale has forced the oil to reach the surface only through vertical borings, chimneys, or pipes drilled upward by volcanic action during the Pliocene and perhaps post-Pliocene times. The evidences of such curious volcanic pipes, well known to geologists in regions having volcanoes of the explosive type, are found here in the form of small isolated cones, ranging from a few feet to four or five hundred feet in

height. These cones of volcanic origin, spread over the coastal peneplain, are easily recognized, being the only objects of any topographical importance in an undulating region. Some of the cones are of solid basaltic lava (sometimes nepheline basalt); others are of basaltic tufa. At the base of these cones, or in their neighborhood, are to be found the greater number and more important seepages of oil. The shale strata have not suffered disturbance near the cones; however, as oil-seepages are found at a distance from volcanic cones, it is presumed that the thick strata have at least been cracked during volcanic outbursts, or that the oil existing there has forced its way to the surface through points of abortive eruption. The truth of the hypothesis herein set forth respecting the geological conditions existing was practically demonstrated during the drilling operations conducted by the Mexican Petroleum Co. at Ebano, near Tampico. In the more highly productive wells of this company the heavy oil, abundantly charged with gas,

has obtained, from but a very few wells around this hill, a daily output of 6,000 barrels. It is my purpose here to show that the conditions above described prevail, with but unimportant variations, in an extensive zone of the Gulf-coast lands, or at least in the southern half of the State of Tamaulipas, and the northern half of the State of Vera Cruz. I have recently made an examination of this region during a trip lasting three weeks, taken for the special purpose of

Poxteitilla Mountain.

height. These cones of volcanic origin, spread over the coastal peneplain, are easily recognized, being the only objects of any topographical importance in an undulating region. Some of the cones are of solid basaltic lava (sometimes nepheline basalt); others are of basaltic tufa. At the base of these cones, or in their neighborhood, are to be found the greater number and more important seepages of oil. The shale strata have not suffered disturbance near the cones; however, as oil-seepages are found at a distance from volcanic cones, it is presumed that the thick strata have at least been cracked during volcanic outbursts, or that the oil existing there has forced its way to the surface through points of abortive eruption. The truth of the hypothesis herein set forth respecting the geological conditions existing was practically demonstrated during the drilling operations conducted by the Mexican Petroleum Co. at Ebano, near Tampico. In the more highly productive wells of this company the heavy oil, abundantly charged with gas,

investigating the oil possibilities there. From data acquired during this trip I am convinced that the reserves of heavy oil existing there, and to be exploited in the future, are enormous, possibly sufficient to supply fuel for the entire railway system of the Republic of Mexico. The only obstacle that seems to stand in the way of the immediate development of the oil industries of Mexico lies in the frequent difficulties arising between the owners of the lands and the oil corporations. These difficulties originate in the extremely unfavorable terms granted to the land-owners by the first contractors or promoters. After this there came naturally a reaction in the form of unreasonable demands made, in turn, by the land-owners. Added to this there exists an inadequacy in the provisions of the law in the matter of working the sub-soil without acquiring the ownership of the surface. The result is that the only safe way to develop the oil business is for the oil corporations to own the fee-simple in the soil. This follows as a consequence of the legal

principle of Mexican law that oil, like coal, is not subject to 'denouncement.'

There is nothing, perhaps, more pleasing to the geologist, after crossing the mountains of the Sierra Madre Oriental in a direction from west to east, than to cast the eye over the coastal plains of the Gulf of Mexico from the view-point of the last elevations of the Sierras facing the plains. If this view is made from the mountains bounding the Huasteca de Vera Cruz, as, for example, from a point near the town of Chicontepec, the whole perspective is still more interesting, on account of the great number of cones, peaks, and pyramids of volcanic origin distributed over the plains. These hills, brown in color, stand out clearly and distinctly from the green plain, which appears, by reason of the distance, to be entirely level and uniform. The most prominent feature visible is the Sierra de Tantima, an isolated group of high mountains standing not far from the shore-line. To the south follow isolated volcanic cones and peaks, real necks, so numerous and of such shape as to present a landscape reminding one of the classic drawings of Geikie and Dutton. Continuing the journey to the Coast, so as to place ourselves in the centre of the region described, we shall see that the cones are distributed without order and independently one of the other. The most important group of necks is in the neighborhood of the intersection of the boundary lines of the cantons of Chicontepec, Tuxpan, and Tantoyuca, and about 50 miles from the sea, from which some of them are visible.

The undulating lands, out of which these cones arise, are, as we have already stated, composed of a thick formation of shale, interbedded with limestone and sandstone in thin layers, the whole probably of upper Cretaceous age. These strata are very slightly folded or undulated, except in a few places. Some of the steeper cones, instead of arising directly from the plain, stand on a conical base, with gently sloping sides, which consist also of basaltic rock, and represent the remnants of small lava streams. The point from which this lava has flowed is marked by the steep peak that crowns the hill.

While it is true that the form of the volcanic necks, caused by erosion, tends more or less to a cone, still the difference between the consistence of the lava in the neck itself and that of its base, has caused certain difference in shape, making the core steep and fantastic in form, whereas the base of the cliff preserves sometimes the original contour of the chimney.

Some of the necks have one side steeper than the other, due to the effect of the strong northern rainy winds so frequent in our Gulf-coast lands during winter. For this reason one of the necks, called Tepenahuatl, 450 ft. high, measured from its upper base, has the form of a triangular pyramid, its northern facet being rocky and steep. Similar, though less pointed, is the neck called Morallillo, standing near Tepenahuatl but lower in altitude. But the most prominent and beautiful basaltic core of the region here described is that called Poxtectitla, a magnificent, solid, basaltic pyramid, measuring 650 ft. above its conical base. Its northern cliff is almost vertical and quite inaccessible, and is finely striated as a result of the columnar structure of the lava. The Tepenahuatl, Morallillo, and Poxtectitla hills are all covered with dense vegetation on their southern slopes. Tepenahuatl and Poxtectitla, as visible from the sea, present the appearance of two black needles, and to the seamen are known as Los Gregorios (The Watchmen). The gently sloping bases of these two hills rise 400 and 500 ft., respectively, above the level of the coastal plain, making the total height 850 and 1,150 ft., respectively. The coast land here is 350 ft. above sea-level.

Some small rocky masses, black in color, stand out

from the large bases of the hills above described, bearing evidence to secondary volcanic outbursts. Around Poxtectitla there are three interesting examples of these volcanic masses; that furthest to the east is called Cerrito de Francia; the one to the extreme north is an excellent example of the pyramid. From the accompanying sketches a good idea can be formed of the general appearance of the mountains mentioned.

To enumerate and describe any number of other hills of volcanic origin to be found in the same region would require more space than is at my disposal. There is one other, however, that demands special mention; it is called Tenexcuila and stands on the Hacienda de Tlacolula. It rises from a large basaltic base, and its appearance, from a distance, is that of the conventional cap of liberty, owing to which circumstance it is known to the natives as El Gorro de la Libertad. Like the other hills of this region, this also displays a steep cliff on the northern side, showing the columnar structure of the basalt. The prismatic division of the lava of the necks is in contrast to the irregular structure of the lavas at the base, which latter structure is similar to that of our common malpais.

The oil seepages being found, as I have stated, in the neighborhood of volcanic hills, are, however, of more frequent occurrence near the isolated volcanic peaks than in places where such peaks are closely grouped and surmounted on large bases. The reason for this apparent anomaly is that the extensive basaltic lava stream at the base of the neck constitutes a formidable obstacle to the upward flow of the heavy oil from the base of the neck to the extremity of the lava stream.

In the coastal plain lying between Tampico, Tuxpan, and Papanla will be found the greater number of volcanic hills and the more important and densely distributed oil-seepages of Mexico. I shall name a few of them. Near the Laguna de Tamiahua there exists a large pool of asphaltic oil, close to the twin volcanic hills known as Los Hermanos. Not far from the Sierra de Tantima is another big, dry, asphaltic lagoon. On the Hacienda de Tlacolula we found two oil-seepages, one on either side of the basaltic hill called Temaxeales. The large volcanic mountain near the Hacienda de Tamatoco gives birth to several exudations of oil. On the eastern side, and not very far from its base is found one of the larger seepages, named La Chapopotera de Juan Felipe, having an extent of one-half mile. The Chapopoteras de Cerro Viejo, those of the Hacienda del Chapopote, and others nearer Tuxpan, are also extensive and important.

Recent discoveries of oil in the State of Coahuila and in northern Tamaulipas show geological conditions somewhat different from those above described and a different quality of oil. These will form the subject of another article.

TIN MINING IN CORNWALL.—Cornish tin mining points to a revival. As long as the Americans delay developing the deposits in South Dakota and in the Southern States, so long will the Cornish mines profit through the lack of rivalry. There is no doubt that an enormous quantity of tin still remains to be extracted from the Cornish hills. Many old mines, which ceased working when the bad times came some 30 years ago, were closed, not because they had not an abundant deposit of tin ore, but because the market was flooded with foreign tin, which was then being produced at a price with which the deep and costly Cornish working could not compete. This foreign supply has now greatly diminished, and the world again turns for its supply to Cornwall. Old mines are being reopened and new claims started.

Technical Methods of Analysis.

By W. A. SEAMON.

*The differences in results obtained by different chemists on the same pulps do not lie so much in the differences of methods employed, or to imperfections in the methods themselves, as in the varying fidelity of the analyst in executing the details of treatment. Imperfection in execution of methods is due in part to the rapidity with which technical chemists are compelled to work; but, I wish to call particular attention to the imperfect execution due to deficient understandings and appreciation of the importance of adhering to the details and successive steps in the methods employed.

Most of the technical methods have been, in recent years, fairly well studied and the *raison d'être* for their successive steps are well understood by the more thoughtful chemists. It, however, frequently happens that, on certain ores, certain details of treatment may be modified, or omitted, with advantage. Chemists who have found these things have, sometimes at least, condemned the original method. So long as their work has been confined to the particular classes of ores on which they have been working they have not discovered the danger, or fallacy, in their modifications; finally, they have come to the conclusion that their modifications are good for all classes of ores, and gross errors have followed—the result of the development of a supreme confidence based upon limited experience.

The criticisms I make are not new and I make them only because I feel we have lost sight of the real essentials for good work, in a vain effort to find a universal method which may be followed mechanically and yet give uniform results. For many determinations I have, from time to time, employed different methods and have usually found, after I had learned to understand the methods, that results by different methods checked well with each other.

First in importance is the preparation of the pulp. How frequently discrepancies in results are eliminated by re-grinding the pulps is a common experience with most technical chemists. The improvement in results comes from the more perfect mixture, made possible by making the particles smaller and more nearly uniform in size, as well as by increasing the working power of the solvents. With the grinding machines now available we should insist upon being furnished with finer ground pulp—the finer the better, particularly for wet determinations.

There is room for great improvement in the type of balance made for analytical work. At present the best balances employed have a sensibility of only one-tenth of a milligram, making the factor of error from the balance, when a half-gram charge is employed, equal to $\frac{2}{100}$ of 1%. This error is probably more than doubled by the rapidity necessary to weigh up a day's run. I have employed a button balance, with a sensibility of one-fiftieth of a milligram, for important wet work with improvement in my results. The small size of the pans is the objectionable feature and has caused me to recommend that balance makers make a balance with short beam, with sensibility of one-fiftieth of a milligram, and capacity of only about ten grams, to be used exclusively for wet work. The pans should be from one and one-half to two inches in diameter. Such a balance will help considerably in doing better work; but it alone will not remedy all evils. No chemist can be sure of his results unless he frequently tests the equilibrium of his balance while

weighing up his day's work—the more frequently the better. The accuracy of the weights should be tested weekly, keeping for this sole purpose a set of standard weights that have been most thoroughly checked. In my own experience I frequently find the equilibrium disturbed to the extent of one milligram after only a few weighings. Such a disturbance corresponds to an error of $\frac{2}{10}$ of 1% in a result. It is foreign from my purpose to discuss the reason for such disturbances of equilibrium; the simple fact that they may occur at any moment is the point to be borne in mind.

When we come to the first acid treatment we reach the stage where most of the discrepancies have their origin. The assayer puts on the specified amount of acid and places the assay on the hot plate, when the active portion of the acid evaporates more rapidly than the water, and takes for granted that decomposition has been accomplished. I happen to have a southern window which receives the sun up to the middle of the afternoon and I always allow the acids to act in the cold for half an hour, then give the assays a sun-bath for another half hour. By shaking the vessels, the analyst can always tell whether or not decomposition appears to be as complete as is possible to secure with conventional treatment; my own experience has taught me that, as a rule, assays are placed too quickly on the hot plate. Then there is the most important point of knowing with a reasonable degree of certainty that the ore has been decomposed; without that knowledge all results must be looked upon with a degree of suspicion.

Evaporations to dryness should be conducted slowly, with care enough to avoid sputterings, thereby throwing portions of the assay on the covers. It is frequently difficult to prevent this, but it should be prevented as far as possible. A thin sheet of paper placed between the plate and the vessel I often find effective. Evaporation over a water-bath is perhaps generally too slow for use by a technical chemist, but a metal box kept filled with dry steam might prove more satisfactory than the hot plate for certain ores.

Uniformity of results in determination of insolubles cannot be expected, and it is far better for us to work to eliminate this determination than to seek to improve it. This matter lies mainly with the ore buyers; if they would fix their schedules to provide for a 'true silica,' uniformity in results could be expected. In my own experience I have come to the conclusion that difference in elevation at which the assay is made affects the results for an insoluble. The same pulps usually give a higher insoluble in Denver than they do here (at Chihuahua, Mexico), where the elevation is nearly 2,000 ft. lower. This may be accidental or due to some other cause; but, as the differences are relatively the same, I have come to the conclusion that the difference in atmospheric pressure causes a sensible difference in the solvent power of the acids.

A great deal of good work has been done by many chemists in working out methods and, as it is important that all should understand the methods thoroughly, it seems to me that in publishing results we should go to extremes in describing the reasons for each treatment; for all of us cannot take the time to work out for ourselves all of these points. If this were done there would be less departures from the methods and there would more rigid adherence to instructions. When the analyst understands the purposes of the treatment and tries to note whether the object of each step in treatment has been accomplished, greater uniformity will be secured and the data for improvement in methods will be found.

Too much stress is laid upon checking with duplicate assays; while duplicate assays should be made to guard

against error, it is of far higher importance to know whether each assay has been properly made. One determination made carefully is of far greater value than any number of assays (no matter if the results do check) in which the analyst cannot say with positiveness that the object of each step in the treatment has been accomplished. The greatest errors I have made have been due to too strong reliance on checks. Checks made on succeeding days are of some value. I think I voice the experience of all technical analysts when I say that good checks are usually made on days when we are not crowded with work, and that when we are crowded good checks are seldom obtained.

In all volumetric work analysts should work with constant bulks, and solutions should be restandardized, at every run, with quantities of the standardizing substance corresponding to the percentage of the constituent in the ore (not because the standard varies daily, but to be surer of constant conditions).

We have heard a great deal about scientific methods of analysis as compared with technical methods, usually to the disparagement of the latter. I wish to place myself distinctly on record as protesting against these claims. Scientific chemists do not check with their so-called scientific methods any more closely than technical chemists do. Examine carefully articles on determinations of atomic equivalents; note the elaborate care employed in preparing absolutely pure salts; also the care and time taken in making the analyses; and yet, with all this care, you will generally find a statement to the effect, that "after rejecting all discordant results the following were selected as sufficiently accurate to serve as a basis for calculation." Absolutely accordant results are unattainable for several reasons, among which may be mentioned imperfections in method and separations, of which none are perfect; there is no balance, or instrument, which does not possess its factor of error—sometimes these factors of error will balance each other, but sometimes they are all plus, or all minus, when the total factor becomes large enough to make differences which cannot be neglected; then there is the individual factor of error (perhaps sometimes known, but probably an unknown variable), for which correction can never be made. While I voice my protest against the validity of the claims for superiority of so-called scientific methods and analysts, I do say that the results of a scientific chemist are more likely to be accurate than those of a technical chemist. Not because of any superiority in method employed, or of ability in the analyst, but for the reason that the scientific chemist can take the time to test each step in his progress, and can know (if he wishes to do so) whether he has accomplished his work, and he is for these reasons better able to speak positively of the value of his work. Most of the technical methods are capable of yielding results equally as reliable as the so-called scientific methods, and many of them are capable of yielding more accurate results. We should not lose sight of the fact that the work of technical chemists is constantly being checked and rechecked, and that any errors are sure to be brought to light. The scientific chemist does not have to measure up to the same searching inspection of his results and, until he has been subjected to it, he has no right to boast of his supposed superiority in skill nor of methods employed.

Technical chemists must work rapidly, and it may frequently be impossible to pause at each step for even a cursory examination to make sure that each step has been accomplished; more can be done, however, in this respect than is usually attempted. I feel that we should educate each other up to a better understanding of the reactions and purposes in our treatments, which will

lead to a greater fidelity in adherence to the details of methods, and will most speedily eliminate the serious differences which from time to time occur.

Another thing much to be desired is the development of a disposition to acknowledge mistakes—when mistakes are made. There is too much bluffing by some of our oldest and best chemists. Having by years of hard work and careful attention built up a business so large that they have to employ assistants (who, from lack of experience or other reasons, occasionally make errors), they will not acknowledge those errors, even when they discover them; they hope to save their reputation by boldly asserting that they have repeated their work and obtained the results reported.

Assayers doing umpire work cannot be too particular in discharging that important function. They should never lose sight of the fact that the chemists, representing the buyer and seller, and working regularly on the ores, better understand the nature of the ores and are, therefore, more capable of judging of the relative values of varying results. Instead of trying to bluff they should make an effort to learn something of the peculiarities of the ores, either by their own work, or through correspondence with the assayers representing buyer and seller. Those of us who are engaged in control and umpire work should never lose sight of the fact that we occupy semi-judicial positions, striving to reach a result just to both buyer and seller.

In common with other chemists I would gladly welcome methods which would give concordant results by simply following them mechanically; but, thirty years' experience as a teacher and practitioner convinces me that such a method is but the idle dream of a lazy person. Thorough training in theory and manipulation; more investigation and fuller freedom in sharing our experiences and the acknowledging of our errors will do more to eliminate cause for criticism of our work than anything else we can do. First, let us understand what we are trying to do; next, do it; and lastly, let us know that we have done what we have tried to do.

Finally, I suggest that (1) the best methods for technical chemists are to be found in volumetric methods, (2) that the best volumetric methods are those in which the constituent to be determined has been most freed from other constituents, previous to titration. The use of aluminum in the separation of copper previous to titration by any conventional method, or by electrolysis, has made the determination of copper the most accurate of any analytical method. This is a purely technical method; for, it has been developed by technical chemists, working alone and in the face of the criticism of scientific workers. I comprehend fully the boldness of this statement, and will gladly defend the proposition, if challenged to do so.

BY FAR the largest proportion of the tin used in the arts is employed for making tin-plates. The total weight of the tin on the plating is said to average 5% of the total weight of the sheet, and there has been in the past great difficulty in recovering this tin by a commercially profitable process, in spite of the high price of the metal. That contained in the solder used in making the joints of the tin can be, and is, recovered by simply heating the tins sufficiently hot to cause the solder to flow; but this process is useless as a means of recovering the rest of the metal, which feat is now being successfully accomplished at Copenhagen by the Bergsøe process. In this a solution of stannic chloride is passed over the tinned surface, when it takes up further tin forming the stannous salt. The latter is then electrotized, the additional tin dissolved is deposited, and stannic chloride re-formed.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

FILTER-PRESS.—No. 862,286; Laurence S. Schoenfeld, Jamestown, Colorado.

In a filter-press, a series of perforated hollow filter members, spaced in unchanged relation to each other during the entire cycle of operations, means to feed matter into the intermediate spaces, means to discharge fluids from the interior of the members, and means for discharging the residue from the spaces.

GRINDING-MILL.—No. 860,782; Max F. Abbé, New York.

A grinding-mill composed of a rotatable cylindrical grinding chamber, a communicating screening chamber, a spiral screen and a spiral conveyor within the screening chamber and rotatable therewith, the convolutes of said screen and conveyor surrounding the axis of the mill, means for returning the tailings from the screen to the grinding chamber, and means for discharging the ground material from the conveyor.

PERCUSSIVE DRILL.—No. 862,770.—Harry P. Taylor, Salt Lake City, Utah.

A percussive device comprising a reciprocating hammer operating in both directions by a charge of working fluid, a tool-rotating mechanism, means for supplying a charge of working fluid against one end of the hammer for reciprocating it in one direction, and means for conducting the said charge of working fluid from the said end of the hammer to against another portion of the hammer and to said tool-rotating mechanism, causing thereby the operation in one direction of said tool-rotating mechanism and the reciprocation of the hammer in an opposite direction to that caused by the supplying of the charge against the end of the hammer.

GRINDING-MILL.—No. 860,788; William R. Cunningham, Bucyrus, Ohio, assignor to The American Clay Machinery Co., Bucyrus, Ohio, a Corporation.

In a grinding and mixing mill, the combination with a rotatable pan, and grinding mullers beneath which said pan rotates, of a hinged door at the side of the pan and opening outwardly therefrom, said door having fixed to it a scraper which is normally out of contact with the floor of the pan when the door is closed, but which is moved toward said floor co-ordinately with the outward movement of the door.

PROCESS FOR SEPARATING MINERALS.—No. 851,600; James F. Latimer, Toronto, Ontario, Canada.

The process of separating graphite and similar substances from rocky matter and gangue, consisting in mingling the crushed ore with oil; delivering the oil-provided mass to, and maintaining it in, an upflowing current of water; centrifugally agitating the mass to separate the components and so accelerate the current as to carry the oil-provided graphite to the top of the water; flowing the so separated graphite away; settling the gangue through a current of reduced speed below the zone in which the material is fed and agitated, and removing said gangue by a downwardly-flowing current.

SMEETING-FURNACE.—No. 862,684; George G. Vivian, Denver, Colo., assignor of one-half to Lafayette Hanchette, Salt Lake City, Utah.

A reverberatory smelting furnace comprising a hearth, a combustion chamber communicating therewith, a slag tap adjacent said combustion chamber, and a matte or metal tap remote from said combustion chamber.

New Traction Engine.

Many experiments have been made in the past few years, looking to the use of traction engines for hauling lumber, ore, etc., and these experiments have proved so satisfactory that the demand for engines for such purposes has largely increased. A saving of 25 to 50% of the cost of hauling can be effected by the use of steam-engines in place of horses, and in many cases where mining and lumbering operations could not be carried on at all on account of the large expense of transporting the product, the use of steam-traction engines has so decreased the cost as to make operations profitable.

The four main requisites of a traction engine are durability, power, ease of handling, and speed. Attention is called herewith to the new Avery undermounted double-cylinder locomotive traction engine. This engine is built upon new principles, and repeated tests have shown that it possesses many points of superiority over the old-style engines where the cylinders are mounted on the top of the boiler. In the latter the boiler is the real frame of the engine, the cylinder and gearing being all attached to the boiler by means of brackets. All the strains incident to heavy hauling come

boiler if one contemplates its having a long life. In this engine all the strains come on the steel frame, and the durability of the engine is thus largely increased. The power developed by the cylinders is transmitted through the gearing and applied to the pull on the load in a direct line, instead of pulling down from the top of the boiler at an angle of from 45 to 90°, as with top-mounted engines. Repeated tests have proved that one of these undermounted engines has a pulling capacity of at least from 15 to 25% more than any other engine of equal rated horsepower. The amount of power that a certain sized engine can develop is one of the most important questions which contractors, lumbermen, and miners will consider, and is certain that an Avery undermounted engine will appeal to them strongly in this respect also.

Commercial Paragraphs.

HENRY TROEMNER of Philadelphia has been given the order for several new scales and balances intended for the San Francisco Mint.

C. A. LUCKHARDT Co., assayers, for the past year temporarily established at Oakland, have entered permanent

Avery Undermounted Double-Cylinder Locomotive Traction Engine.

on the boiler, which soon shows the effect of the steady pulling in leaky bolts and loose brackets, and the life of such an engine for continuous hauling purposes is short. The fact is that while the demand for traction engines for hauling has grown and has been brought to the attention of manufacturers, most of them have failed to appreciate how different are the demands on an engine that is to be used for continuous hauling purposes as compared to a threshing engine, a large part of whose power is to be expended in belt-work for driving the separator. Some manufacturers have attempted to meet this demand by simply reinforcing their gearing and building larger engines, but in doing so they have not in any way avoided the real difficulty, that of relieving the boiler from the great strains incident to hauling heavy loads. The Avery Manufacturing Co., of Peoria, Ill., having built one of the best top-mounted engines on the market, saw that the demands on an engine for hauling purposes were entirely different from those on an engine that was to be used for threshing and, fully realizing that no top-mounted threshing engine could successfully meet these requirements, they devised the new Avery undermounted double-cylinder engine. In this engine the cylinders and gearing are mounted on an independent steel frame-work, and the boiler is entirely relieved of all strains. All that is required of it is simply to generate steam, which it is easily seen should be the only thing required of the

quarters at 53 Stevenson St., within a few feet of the site of their old plant, which they occupied for nearly half a century before the fire that devastated San Francisco.

THE WM. POWELL Co. of Cincinnati has mailed a catalogue of their brass and iron specialties. A valuable series of tables and rules is bound in with the catalogue, giving in a concise form information that every engineer and shop manager requires in his daily practice.

G. G. GATES, 149 Beale St., San Francisco, who installed the first successful canvas tailing plants in Calaveras and Amador counties, has arranged with the Goodyear Rubber Co. for the manufacture of a new concentrator-belt for both end and side-shake machines of the Frue and Johnson types. He is also making a new tandem-table machine of the Wiltley type.

THE ECLIPSE DRILL SHARPENING MACHINE MFG. Co., of 1,701 Blake St., Denver, has recently installed two of its drill-sharpeners at the plant of the Colorado Central Power Co., at Shoshone, near Glenwood Springs, Colo. The power company is installing a large plant of machinery for generating electric power for use on the western slope of the Rocky mountains. Jos. Retallack, the manager, has recently placed on the market a coke furnace and sliding rack for heating drill-bits, to be used in connection with the drill-sharpener.

Editorial.

WE ARE INFORMED that the United States Geological Survey is taking up the examination of mineral claims located on forest reservations. Mr. Waldemar Lindgren has charge of this work. The Survey has already done good service in getting evidence concerning the mineral character of land claimed to be agricultural by railroad companies and others anxious to acquire large tracts of the public domain.

ACCORDING TO information emanating from a press bureau, it appears that F. Augustus Heinze is willing to work with the Guggenheims; at least, he is not desirous of competing with them in the ore market of Salt Lake. The building of the new Heinze smelter on the south shore of the lake is, we are assured, no sign of an impending conflict between clever people, but only the evidence of the irrepressible activity of an energetic captain of industry. As they say in funeral notices: Country papers please copy.

THE CONVICTION of several men implicated in the imposture of the Lost Bullion Spanish Company at Denver, is another credit to the post-office inspectors. Two mining engineers are among those convicted, and it is likely that the punishment of them will serve as a warning. On the face of it the whole affair was a fraud, although no worse than many schemes hawked in the pages of several so-called mining papers. It is a pity that the regulations against the fraudulent use of the mails cannot be enforced against the periodicals which, under the guise of giving advice, are the lure of the faker.

REVERBERATIONS of the financial storm in New York and Boston are still echoing across the continent. The President's speech has prodded several editors to sarcasm and even to protest, and all of these molders of public opinion are not hirelings of the financiers. To the people on Wall Street the vicinity of Washington is ominous and to those that live in New York the activity of the Stock Exchange is a vital fact, for speculation is so general on Manhattan island that few men, even professors and editors, escape the snare of it. Hence the President's lack of sympathy for the nerves of the speculator and his disregard of the intense strain to which business is being subjected, provoke their resentment. Mr. Roosevelt ought to have, so they say, more feeling for a delicate situation, and he ought to recognize the danger of an assault upon national credit. "Into a room where credit lies nervously ill, he bursts with a shout and a club," so says the *Evening Post*. And yet those at a distance, away from the dust arising from "the stamping ground of the great herd" on Manhattan

island, are in sympathy with the President in his vigorous efforts to assert the right of the community to check the predatory methods of the big corporations. Temporary disquiet on the bourses of the country is bound to arise from any attempt to disturb illegal practices among those in control of public utilities, but this should not deter the enforcement of justice. In the meanwhile it is well once more to state that the sickly condition of the 'Street' is not due to threats against unscrupulous financiers; it is the evidence of a worldwide condition, varied by local characteristics. During the present month the decline in stocks quoted upon the London Exchange has reached the staggering total of \$680,000,000. Since the beginning of 1907 the depression is measured by \$1,725,000,000, of which one-third is in American railroad shares. The biggest losses have been in the South African mining market, where quotations have been amputated to the extent of 25 per cent. No wonder the money markets are groggy. The water is being squeezed out of stocks and the process leaves a feeling of acute discomfort. It was inevitable.

OUR CORRESPONDENT in Mexico sends us an important letter concerning the increased freight rates levied by the railroads. It will be remembered that the Mexican Government has recently effected a consolidation of the main lines within the Republic, and it was hoped among those engaged in mining that this would mean a better management. During the last year or two the shortage of cars on the Mexican Central and the consequent slow delivery of the material needed in mining and smelting has seriously hindered profitable operations. Some of it was due to a big increase of business, but much of the car shortage was traceable merely to lack of management, as has been the case on this side of the Rio Grande. Now we learn from our correspondent that not content with a wretched administration, the railroad companies propose to increase their tolls to a prohibitive degree. It is time for mine operators to make a vigorous protest.

The Hearst Memorial.

ON OTHER PAGES of this issue we give an account of the ceremony that marked the formal opening of the new Mining Building of the University of California. The building is a memorial to George Hearst and is the gift of his widow, Mrs. Phoebe Hearst, whose thoughtful munificence has provided the University at Berkeley with several splendid structures and a general plan of construction destined to make the State University worthy of its noble site at the foot of the Contra Costa hills, facing the Golden Gate.

It is claimed, and justly, that this is the finest building in existence that is devoted solely to the cause of mining education; certainly it is a noble edifice, built of an exquisite stone and designed both as to beauty and utility in such a way as to do honor to the donor and the architect. We rejoice in the good fortune of the department of which our friend Professor Christy is dean, and in the added facilities provided for a college, the gradu-

ates of which constitute a notable group in the profession of mining and metallurgy.

But there is another aspect of the event that stirs thoughts not unmixed with regret. At the opening, the generous woman to whom the University owes the building—and much more—was accompanied by her son William Randolph Hearst, one of the most prominent of the public men of America. As a newspaper proprietor on a tremendous scale, as a candidate successively for Mayor and Governor of New York, as an aspirant for the Presidency of the United States, he has loomed large in the public eye during the last few years. He has given to the University of California its Greek theatre, one of the truly classic buildings on this continent, and he participates in the gratitude evoked by the munificence of his mother. For this the community honors him, but, at the risk of seeming barbarously ungracious, we venture to say, in a paraphrase of Dooley and Kipling, that "the more we remember, the less we forget." No university in America today is so potent an educational force for good as Mr. Hearst's newspapers are for evil. In four or five cities of this Republic he publishes a crop of journals, each of which preaches every day the gospel of hatred and undermines all the best instincts of popular government. A benefaction to a State University deserves the thanks of the community, and will get it, but not without a thousand regrets that the multifarious abilities of a forceful man should be expressed in a species of enterprise that is so utterly anti-social. At the opening of the building dedicated to his father's memory, he made a good speech, full of optimistic patriotism calculated to stir a vibrant chord in the young men before him—the young men whose best impulses and highest principles are debauched by the wretched sheets scattered broadcast by him every morning in the name of journalism. What a power for good the half dozen Hearst newspapers could be if they were different in every respect, except ability and energy! It is a fact that the average citizen reads a serious book once in six months and a newspaper twice a day. That is why the daily newspaper is so potent a force in shaping the thought of the country. It is the medium through which the members of a modern community get the larger part of their information on current affairs. The publisher of a single paper has great power to educate or pervert the public mind, and the proprietor of half a dozen dailies has a proportionately larger scope for disseminating ideas, good or bad, and distributing information, true or false. If the periodicals controlled by Mr. Hearst were pulling on the same side as the University to which his honored mother has given so generously, then the cause of good citizenship would be enormously strengthened; but as it is now, the University is dedicated to ideals which he does his best every day to shatter. By preaching the gospel of hatred, by stirring the mud puddles of social life, by misinformation on current affairs, by the slander of good men, by the support of bad ones, by a policy that is wholly anti-social, he is doing his best to oppose one of the chief purposes of an American University, namely, the development on right lines of popular government in these United States.

By the Way.

At the recent meeting of the British Association for the Advancement of Science, the President, Sir David Gill, said:

One of Clerk Maxwell's lectures at Aberdeen, when I was a student under him there, in 1859, ran somewhat as follows:

"A standard, as it is at present understood in England, is not a real standard at all; it is a rod of metal with lines ruled upon it to mark the yard, and it is kept somewhere in the House of Commons. If the House of Commons catches fire there may be an end to your standard. A copy of a standard can never be a real standard, because all the work of human hands is liable to error. Besides, will your so-called standard remain of a constant length? It certainly will change by temperature, it probably will change by age (that is, by the rearrangement or settling down of its component molecules), and I am not sure if it does not change according to the azimuth in which it is used. At all events, you must see that it is a very impractical standard—impractical because, if, for example, any one of you went to Mars or Jupiter, and the people there asked you what was your standard of measure, you could not tell them, you could not reproduce it, and you would feel very foolish. Whereas, if you told any capable physicist in Mars or Jupiter that you used some natural invariable standard, such as the wave-length of the D-line of sodium vapor, he would be able to reproduce your yard or your inch, provided that you could tell him how many of such wave-lengths there were in your yard or your inch, and your standard would be available anywhere in the universe where sodium is found."

That was the whimsical way in which Clerk Maxwell used to impress great principles upon us.

Now the scientific world has practically adopted Maxwell's form of natural standard. It is true that it names that standard the metre; but that standard is not one-millionth of the earth's quadrant in length, as it was intended to be; it is merely a certain piece of metal approximately of that length.

It is true that the length of that piece of metal has been reproduced with more precision, and is known with higher accuracy in terms of many secondary standards, than is the length of any other standard in the world; but it is, after all, liable to destruction and to possible secular change of length. For these reasons it cannot be scientifically described otherwise than as a piece of metal whose length at 0° C. at the epoch A.D. 1906 is = 1,553,164 times the wave-length of the red line of the spectrum of cadmium when the latter is observed in dry air at the temperature of 15° C. of the normal hydrogen-scale at a pressure of 760 mm. of mercury at 0° C.

The ancient philosophers were confident in the adequacy of their intellectual powers alone to determine the laws of human thought and regulate the actions of their fellow men, and they did not hesitate to employ the same unsupported means for the solution of the riddle of the universe. Every school of philosophy was agreed that some object which they could see was a fixed centre of the universe, and the battle was fought as to what that centre was. The absence of facts, their entire ignorance of methods of exact measurement, did not daunt them, and the question furnished them a subject of dispute and fruitless occupation for twenty-five centuries.

But astronomers now recognize that Bradley's meridian observations at Greenwich, made only one hundred and fifty years ago, have contributed more to the advancement of sidereal astronomy than all the speculations of preceding centuries. They have learned the lesson that

human knowledge in the slowly developing phenomena of sidereal astronomy must be content to progress by the accumulating labors of successive generations of men; that progress will be measured for generations yet to come more by the amount of honest, well-directed, and systematically discussed observation than by the most brilliant speculation; and that, in observation, concentrated systematic effort on a special thoughtfully selected problem will be of more avail than the most brilliant but disconnected work.

By these means we shall learn more and more of the wonders that surround us, and recognize our limitations when measurement and facts fail us.

Huggins's spectroscope has shown that many nebulae are not stars at all; that many well-condensed nebulae, as well as vast patches of nebulous light in the sky, are but inchoate masses of luminous gas. Evidence upon evidence has accumulated to show that such nebulae consist of the matter out of which stars (that is, suns) have been and are being evolved. The different types of star spectra form such a complete and gradual sequence (from simple spectra resembling those of nebulae onwards through types of gradually increasing complexity) as to suggest that we have before us, written in the cryptograms of these spectra, the complete story of the evolution of suns from the inchoate nebula onwards to the most active sun (like our own), and then downward to the almost heatless and invisible ball. The period during which human life has existed on our globe is probably too short—even if our first parents had begun the work—to afford observational proof of such a cycle of change in any particular star; but the fact of such evolution, with the evidence before us, can hardly be doubted. I most fully believe that, when the modifications of terrestrial spectra under sufficiently varied conditions of temperature, pressure, and environment have been further studied, this conclusion will be greatly strengthened. But in this study we must have regard also to the spectra of the stars themselves. The stars are the crucibles of the Creator. There we see matter under conditions of temperature and pressure and environment, the variety of which we cannot hope to emulate in our laboratories, and on a scale of magnitude beside which the proportion of our greatest experiment is less than that of the drop to the ocean. The spectroscopic astronomer has to thank the physicist and the chemist for the foundation of his science, but the time is coming—we almost see it now—when the astronomer will repay the debt by wide-reaching contributions to the very fundamentals of chemical science.

By patient, long-continued labor in the minute sifting of numerical results, the grand discovery has been made that a great part of space, so far as we have visible knowledge of it, is occupied by two majestic streams of stars traveling in opposite directions. Accurate and minute measurement has given us some certain knowledge as to the distances of the stars within a certain limited portion of space, and in the cryptograms of their spectra has been deciphered the amazing truth that the stars of both streams are alike in design, alike in chemical constitution, and alike in process of development.

But whence have come the two vast streams of matter out of which have been evolved these stars that now move through space in such majestic procession?

The hundreds of millions of stars that comprise these streams, are they the sole ponderable occupants of space? However vast may be the system to which they belong, that system itself is but a speck in illimitable space; may it not be but one of millions of such systems that pervade the infinite?

We do not know.

Personal.

E. W. STERRINS is at Spokane.

M. E. MACDONALD is at New York.

CHARLES BUTTERS is at Washington.

W. H. RADFORD is at Fairbanks, Alaska.

ALBERT BURCH has gone to Wardner, Idaho.

J. H. CURLE is on his way to the Malay States.

T. H. LEGGETT will open an office at New York.

DOUGLAS WATERMAN has returned from work in Plumas county.

J. R. CAHILL is visiting the mining regions of Peru and Bolivia.

W. E. DEFTV is examining mines in Yavapai county, Arizona.

HAROLD S. GAY is in San Francisco on his return from Honolulu.

JOHN B. KEATING, of the Bully Hill mine, is at San Francisco.

J. PARKE CHANNING is expected at Seattle on his return from Alaska.

THEODORE J. HOOVER will come to the West from London in September.

JAMES M. HYDE is with Charles Butters & Co. at Virginia City, Nevada.

LUTHER W. BAHNEY is now instructor in metallurgy at Stanford University.

M. T. CHESTNUT & SON have opened a Denver office in the Century building.

HERBERT HAAS is now in the service of the Union Iron Works, San Francisco.

SEELEY W. MUDD sailed on August 22 from Liverpool on his return from Europe.

M. F. PERRY is manager for the Creston Colorado Co., at Torres, in Sonora, Mexico.

JOHN A. CHURCH sailed from San Francisco on the *Asia* for Nagasaki on August 27.

NEWTON B. KNOX passed through San Francisco on his way from Japan to London.

C. W. EVANS has returned to Ashland, Oregon, from the inspection of mines in Curry county.

GEORGE S. TYLER, superintendent of the Nelson mine, Quiney, Cal., has been in San Francisco.

S. H. BROCKUNIER has not accepted the mine management at Silverton. He is now at Denver.

H. VINCENT WALLACE has returned to Nogales from a visit to the dredging districts of California.

CHARLES PALACHE, professor of mineralogy in Harvard University, is at his home in Berkeley.

CHARLES JANIN has completed the inspection of mines near Silver Cliff, Colorado, and is now at Denver.

H. A. SHIPMAN and R. J. GRANT have taken new offices in the Ernest & Cranmer building, at Denver.

W. S. G. TODD is superintendent for the East Fork Development & Mining Co., at Boulder Creek, California.

E. J. BUMSTED has left Velardeña, to become manager of the San Francisco mine, at Ocotlan, in Oaxaca, Mexico.

HARTWELL CONDER has joined the firm of Alexander Hill & Stewart, mining engineers, and will act as their Australian representative, with offices at Melbourne.

Obituary.

THOMAS CORNISH, formerly superintendent of the Terrible and other mines near Georgetown, and then of Stratton's Independence, at Cripple Creek, died on August 22 of pneumonia, while at Stenika's ranch, in southern Nevada. He was 57 years old, and had been engaged in mining in the Silver Plume, Leadville, and Cripple Creek districts since his arrival in Colorado in 1868.

General Mining News.

ALASKA.

While it is true that the Guggenheims have three dredges in the process of installation on Hunker, and own a good deal of ground, still there are many patches of good ground which are not controlled by them, especially a large number of creek claims on upper Hunker. Among the Hunker hill claims that have not been gobbled up are the Temperance, Whisky, Delhi, Nugget, Australian, and various others, while among the creek claims that have not been grabbed by the giant combine are the Gold Bottom above No. 30, Last Chance, Hester, Henry Gulch, and Eighty Pup.—The Guggenheim holdings on the main Hunker extend from the mouth to 30 below, with the two exceptions of the claims 47 and 49, now being worked by individuals, and take in Dago hill. Above 30, or virtually from the lower end of Gold Bottom town to the head of Hunker, are 42 claims, and from the town to the head of Gold Bottom creek are 40 claims, making a total of more than 80 creek claims contiguous on the upper end, which

women, in Minneapolis, to take over the hornblende-garnet vein near the mouth of the Stikine river, about seven miles from Wrangell. The garnets are hard and pure, and will be cut and polished in Minnesota.—Coal, coke, and ore are arriving at the Hadley smelter, and a long and continuous run should be possible. There is still a little difficulty in getting fluxing ores for the charge.—The Alaska Galena Co. has been organized to develop the Moonshine properties, purchased from McCallion, Hoover & Patterson. W. W. Catlin is the manager and Milnor Roberts superintendent. A camp has been established on the beach on the south arm of Cholmondely sound, seven miles from Chomly, and a trail built from the beach to the mine on the ridge of Granite Mtn. About 100 tons of galena ore has already been mined.—A shipment of 350 tons of gypsum was recently made from Chicagoff island, and 100 tons of marble from Calder.

The U. S. Geological Survey is doing a great deal of work this season, investigating the mineral resources of Alaska. The copper deposits in the valley of Chitina river, a tributary of Copper river, are being re-examined by Fred H. Moffit, assisted by A. G. Maddern. This field is important because of the large amount of development now going on within it. Mr. Moffit will make a reconnaissance down Copper river, and may visit the more important districts of the Prince William Sound copper district.—Investigations of the coal resources of the Territory, begun last year, are being continued by W. W. Atwood, who reached south-eastern Alaska in the early part of May, and spent a month studying the coal-bearing rocks of that district. He next visited the Yukon coalfields, as far as they are accessible from the Yukon river. He is assisted by H. M. Eakin.—In accordance with the plan of mapping the important mining districts in detail, the ore deposits of the Ketchikan mining district, in Kasaan peninsula, Prince of Wales island, south-eastern Alaska, are being studied by C. W. Wright and Sydney Paige. A contour map on a scale of an inch to the mile is in preparation as a base for the work.—The tin deposits of Seward Peninsula, both lode and placer, are being examined by Adolph Knopf, who is to make a special study of the manner of occurrence and mode of origin of the ores.—A contour map of Kasaan peninsula, on the

Map of Alaska.

are not gobbled. The Gold Bottom ground nearly, if not all, has been organized into one group. S. G. McLellan was the organizer. Temperance hill and a number of other hills and benches adjoin upper Hunker and Last Chance.—In the development of the Candle Creek placers, 11,000 tons of coal were used last year. This coal was mined within 12 miles of where it was used. Candle creek is a tributary to Kiwalik river, which flows into Kotzebue sound.

In the Ketchikan district there is a congestion of ore at the Jumbo, owing to the lack of transportation facilities, and all the hunkers, holding 4,500 tons, are full. The daily production of the mine is about 100 tons of ore.—The Mt. Andrew mine can arrange for the freighting of only about 4,000 tons per month.—The Cymru property will soon be worked again. About 900 tons of ore from this mine are stocked at Coppermount, awaiting shipment.—The Red Wing has just shipped a cargo of ore to the Tacoma smelter.—About 50 sacks of copper ore were recently shipped from the Peterson property on Cat island.—J. H. Hazlett, representing Chilberg & Davidson of Seattle, who recently purchased the Goodro & Thomas copper property on Karta bay, has gone to the mine for the purpose of making a 500-ton trial shipment to the smelter, and if the returns are satisfactory, an aerial tramway and bunkers will be built.—E. W. Molander has gone to the Hadley smelter to install a hot-blast attachment to the smelting furnace, which is expected to effect a saving of coke.—The Alaska Garnet M. Co. has been organized entirely by

inch-mile scale, is being made by D. C. Witherspoon. On the completion of this work Mr. Witherspoon will map, on the scale of one-half inch to one mile, the region between the international boundary west of Dawson, Y. T., and Fairbanks, Alaska, adjoining the southern boundary of the area already mapped in this region. J. W. Bagley is assisting him.—Alfred H. Brooks, the geologist in charge of the Division of Alaskan Mineral Resources, will be engaged in office work in Washington until mid-summer. He will then visit southeastern Alaska, the Fairbanks district, and Seward Peninsula, paying particular attention to economic developments in the various fields.

ARIZONA.

COCHISE COUNTY.

Parker Woodman has been appointed to the superintendency of the Copper Queen mines, to succeed S. W. Clawson.—A strike of copper ore is reported from the Scherrer property at Johnson, at a depth of 45 ft. San Francisco people bought the property some weeks ago, and Emile Allen is the manager. Two carloads of ore have been shipped to Douglas, and two more await shipment. This property adjoins the Republic, which has been a regular shipper for two years.—George Myers reports a strike on the His Royal Highness claim of the Black Queen group, two miles east of Paradise, near the top of the divide between Silver creek and Round valley. The property is held on a two-year bond and lease. Some good ore is being exposed

in other properties at Paradise. The Snowball shaft at the Savage is down 170 ft. and some good ore is showing. The Seanland tunnel, after running 450 ft. and attaining a depth of 300 ft., shows good ore, and in the Horace incline on the same group the ore has held to the present depth of 150 ft. —The Doran & Gallagher shaft is 100 ft. deep.

MOHAVE COUNTY.

(Special Correspondence). — The Arizona-Southwestern Copper Co. has commenced sinking a 200-ft. shaft on the Siamese group of claims in the Cedar Valley district, situated between Big Wallapai Mtn. and Hackberry, to cut a vein that crops out on the surface, and which can be traced for a long distance. In a 16-ft. shaft, samples have been taken running \$28 in gold, copper, silver, and lead. Copper is the predominant metal. The ore is an excellent concentrating material. There are many natural advantages, such as timber and water, but as the district is a new one, this is the first company to undertake mining. There is a small hoisting plant on the ground, which was packed in on burros in sections. This plant will suffice to reach the 200-ft. point. The officers of the company are: Geo. L. Hibbs, president, Doylestown, Pa.; L. Hoffman, vice-president and general manager, and J. H. Hoffman, secretary and treasurer.

Prescott, August 27.

The first payment on the McCracken group of mines was made this week. The mines are about 30 miles from the Santa Fe railroad, and if the deal goes through it will mean much to this county.

YAVAPAI COUNTY.

(Special Correspondence). — The outlook for a good ore-body in the Little Daisy shaft is growing brighter as sinking progresses. The manager states that the present hoist will soon be replaced by a new one of larger capacity, another boiler is to be installed, and as soon as a site is determined on, a double-compartment working shaft will be sunk. — The Jerome Mines Development Co. has for several months been operating a diamond-drill on its property. It is stated that they have cut sufficient ore to warrant the opening of a mine, and are at present sinking a double-compartment shaft. — Superintendent Martin, of the Sycamore Mining Co., reports that work on the new shaft is progressing rapidly, having gone 70 ft. in 30 days, and that the new No. 9 Cameron pump is handling the water easily. — A tunnel is being run by contract on the Eureka property, in Black canyon, to cut the main vein. The contractor reports good headway, and says that another 100 ft. ought to show something good. — Tom Taylor, superintendent of the United Verde smelter, has returned to Jerome after an extended absence.

Jerome, Aug. 25.

The hoisting plant and air-compressor have been installed at the mine of the New England-Arizona M. Co., near McCabe, and power drills are at work. — Good reports come from the Nigger Brown mine in the Black Canyon district, where the shaft is down 200 ft. — The Flour Gold Placer M. Co., operating on Humbug creek, is employing 35 men, and the flume will soon be finished. — A hoisting plant has been purchased to sink a double-compartment shaft on the property of the Logan Copper Co., in Copper Basin. — Copper ore is exposed in the bottom of the 300-ft. shaft on the Storm Cloud group in the Hassayampa district, 12 miles south of Prescott. — The New York-Arizona Copper Co. has its shaft down 460 ft., in the Black Hills. Nearly 200,000 gal. of water per day must be handled. — John S. Jones announces that a reduction plant, with a capacity of 120 tons per day, will be built at the Little Jessie property.

CALIFORNIA.

BUTTE COUNTY.

George H. Sisson has made partial payments toward the purchase of several properties in the Magalia district, and it is reported that he has purchased an option on the McGibbons mine, and on the Matheson property. — A good deal of development work is being done on the Mammoth Channel property.

CALAVERAS COUNTY.

The members of the local miners' union at Angels Camp voted to reject J. V. Coleman's offer of 9 hr. per day for underground workers, top men to work 10 and 12 hr. per day, as before the lockout. Subsequent to this action, Coleman withdrew his offer.

NEVADA COUNTY.

(Special Correspondence). — It is reported that sinking will soon be resumed at the Central shaft. A large amount of development work is under way, and the mine is looking well. — At the Brunswick the working force is being steadily increased and the mill is treating ore of a good grade. — The work of unwatering the Kenosha is progressing rapidly. — The Niagara is showing up well, and the management is pleased with the results thus far obtained. — The New York-Grass Valley Co. announces that it must secure \$65,000 before October 1, or suffer the attachment of its property. To meet this difficulty, the Prudential Mining Co. has been organized to raise sufficient funds. If the stockholders pay off the indebtedness in the stipulated period, the property will remain in their hands. All title to the mine will be conveyed to the Prudential Co., which will be composed of New York-Grass Valley shareholders. They have received circulars from the management urging them to join the new company in order to protect their interests. — In the Randolph Flat section, some promising prospects are being developed. — Several small placer properties are being operated on Deer creek, and some of the men are getting good returns. The late rains furnished an abundance of water for placer mining in this district. — Conservative estimates indicate that the production of the Grass Valley district for the present year will be approximately \$1,300,000. The miners' strike and heavy rains in the spring greatly retarded production. — The California mine is shipping copper ore to Kennett. A large body of ore is being developed. — The copper miners of this county are seriously considering the installation of a small smelter at some convenient point. At present only the highest grade copper can be profitably mined, but with the installation of a nearby plant, the deposits of low-grade ore could be handled at a profit. — The Miners' Union has declared war on the wood trust, and will set aside \$10,000 to purchase firewood for its members. The union officers state that they will ship in wood from outside districts and sell it at cost prices.

Grass Valley, Aug. 27.

The Horseshoe Mining Co. has purchased the Phoenix mine, on Gold hill, from the Eastern owners. The same company owns the Eclipse property. W. B. Simmons will be in charge of the work, and W. J. Bruce of Tonopah is the prime mover in the organization. The property was last worked eight years ago, when a hoisting and pumping plant was erected and a 10-stamp mill built. The shaft is down 500 ft., and was once a good producer, being known as the Sneath & Clay property. — Some good rock has been encountered in the Niagara mine, near Newton, at a depth of 200 ft. This company recently levied an assessment of 5c. per share on its stock, to meet the final payment due the Williams brothers on the purchase price of the property. C. A. Hurst, representing a pool of shareholders in Illinois, is said to control the company. — A big restraining dam is to be built across the Greenhorn river, above the Narrow Gauge bridge, and the Red Dog gravel mine, owned by J. S. Goodwin & Co., will be hydraulicked. Robert Richardson will superintend the construction, which will require two months, the dam being 35 ft. high. The gravel to be worked is in some places 200 ft. deep. — The Banner shaft has been pumped out and all the workings are dry. The shaft is 900 ft. deep, and drifts are to be run each way on the vein. Bulkheads will be built in the upper levels, to hold back the water and save a large amount of pumping. It took 38 days to unwater the mine, and mining men think it may become a good producer. — A new compressor for the Union mine, on Banner hill, has arrived and is being installed. When it is in place, sinking will be resumed.

services rendered.—G. G. Gates is building 20 of his new concentrators in Oakland for the Eagle-Shawmut M. Co.—It is stated that Nevada capitalists have taken over the Black Oak mine, and will work it on a large scale after unwatering it.

COLORADO.

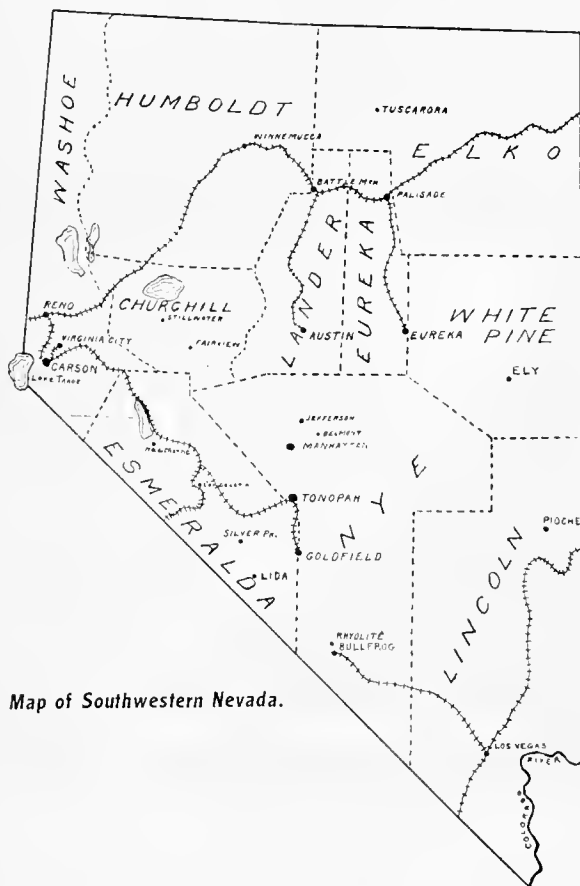

TELLER COUNTY.

With dividend payments running all the way from \$3,000 to \$120,000 by leading mines within a few days' time, and a monthly production of over a million dollars, there is no discussion here as to whether mining should be classed among the gainful occupations. The mines of Bull hill continue to hold the record for production. The recent strike of the Isabella at the 1,000-ft. level is still the talk of the camp. The Delmonico, a portion of the old Stratton estate, is being vigorously developed by its new owners, the Consolidated Copper Creek Co., whose shaft is going down rapidly.

NEVADA.

ESMERALDA COUNTY.

The production of the Goldfield mines amounted to 3,417 tons with an estimated value of over \$350,000 for the week

Map of Southwestern Nevada.

ending August 23. This total is low on account of the shut-down at the Mohawk, since Sunday, the eighteenth, owing to the walkout of the miners, and the closing of the Combination since the twenty-first, from a similar cause.—For the week, the Nevada Goldfield Reduction Works received consignments of ore as follows: Little Florence, 425 tons; Mohawk, 240; Mowhawk Combination, 700; Higginson, 106; McNaughton, 41; Red Top, 435; Frances Mohawk, 15; Hayes-Monette, 125; Rogers Syndicate, 90; Total, 2,177 tons. Total mill value about \$272,125. For the same week the Western Ore Purchasing Co. received consignments of ore as follows: Mohawk Jumbo, 603 tons; Mohawk Ledge, 92; Florence Leasing Mining, 12; Mohawk, 43. Total, 750 tons. Average value about \$93,750.—The old trouble about change-rooms is again up between the miners and operators. The union miners repudiated their agreement with the Consolidated officials, and walked out at the Mohawk and Combination mines. Their chief contention seems to be that they must be watched over in the change-rooms only by members of the Western Federation of Miners, and a general strike may follow, resulting in Goldfield being an open camp.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Winnipeg Mining Co. was organized April 1, 1905, and capitalized at \$1,500,000. The directors are C. W. Clark and Arch. Wright, of Winnipeg, and E. R. Fraser, W. R. McCracken, and Charles Garber, of Spokane. Joseph L. Lancaster is the superintendent. The company owns the Hawkeye, Laughing Water, Governor Rodgers, Struck Luck, St. Barnard, Eagle, Waterloo, and Hawkeye No. 3 claims in one group, on Lambert creek. The property was recently equipped with a Leyner straight line eight-drill compressor, and an Atlas 100-hp. tubular boiler. An Ingersoll-Rand drill is in commission, and two more have been ordered. This may develop into one of the most valuable mines in Ferry county. An incline shaft has been sunk 240 ft. on the foot-wall of the vein, a horse-whim and gasoline engine having been used for hoisting purposes. An adit is in 1,070 ft., and connected with the workings from the shaft. It passes 210 ft. through glacial drift, 600 ft. through decomposed granite, over 200 ft. through altered syenite and into an immense vein of iron sulphide ore, with gold, silver, and copper. The formations intersected are intercalated with narrow beds of limestone. Three stringers of ore, from 6 to 18 in. wide, with rich streaks of chalcopryite, are bedded in the granite, in low-grade quartz. The main vein has an approximate width of 70 ft. on this level and was first encountered in the adit on the hanging-wall side. No drifts have yet been driven on either the hanging wall or foot-wall by which any information can be had on the length of the orebody. The shaft is in ore from the collar to a depth of 115 ft., on a 56° pitch of the vein. It then goes down successively through 10 ft. of porphyry, 20 ft. of syenite, 15 ft. of porphyry, and 70 ft. of ore. A sump follows the foot-wall an additional depth of 12 ft. in ore. The strike of the vein is N 30° E, the pitch is N 60° W, at an angle of 56°. A drift has been driven 65 ft. through ore on an intermediate level, at a depth of 80 ft. Another level has been opened from the shaft at a depth of 140 ft., where the width of the pay-shoot is about the same as in the adit level. On both of those levels stations are being cut, preparatory to stoping. A station is being cut on the adit level. Taken from the surface to the lowest level, limonite, hematite, siderite, magnetite, pyrite, marcasite, pyrrhotite, and arsenopyrite are found in the ore. A force of 18 men is employed by the company. The distance from the portal of the adit to the ore-bins of the Belcher Mtn. railway siding is less than 80 ft. The stockholders of the Winnipeg Mining and Belcher Mtn. railway companies are almost identical, which will insure the lowest rates for transportation from the mine to the main lines in transit to the smelters. Work on the Belcher mine will shortly be resumed, with new plans, under new management. The Bortle tunnel is in 77 ft. and is being driven under contract, with three shifts of four men each.—The cross-cut from the No. 2 adit on the Copper Key mine has cut the orebody for 71 ft., and there is no sign of the hanging wall.—On the Oversight group a new tunnel has been started to tap the Pin Money vein at 12 ft. lower elevation than the bottom of the shaft, for the purpose of driving on the vein and stoping. It will have 80 ft. in all to run. The open-cut has crossed another vein, eight feet in width, with rich ore on the hanging wall identical in appearance with that of the Pin Money vein.—In the Iron Chief, a vein of iron sulphide ore has been followed for 100 ft. by an adit and about 150 ft. by drifts. A new tunnel was driven 75 ft., and ore of a similar character was encountered. It is all of shipping grade, although the vein is narrow as compared with most others in the neighborhood, and is believed to be a stringer from the main vein.

Republic, Aug. 28.

STEVENS COUNTY.

(Special Correspondence).—Work has been resumed on the Populist group, on Jumbo Mtn., and the property is looking well, with some good ore in sight.—Seven miners are employed on the Chief & Butte mine, on Pierre creek, a controlling interest in which is under bond to the Green-

ough brothers. The property is looking so well that there seems no doubt that the bond will be taken up.—The Hibernia Mining Co. is applying for a U. S. patent on the Abe Lincoln and Bryan claims. From the bottom of a shaft on the former, 108 ft. deep, a body of ore 40 ft. wide, averaging \$9 per ton, has been intersected. It is proposed to extend an adit from the Viking ground, adjoining to cross-cut the vein on the Abe Lincoln claim at a depth of about 1,000 ft.—The Viking Copper M. Co. owns the Minnie Healy, St. Lawrence, and Mountain Consolidated claims, west of the Hibernia Co.'s ground, on the east side of Kettle river, near Rock Cut. Considerable work has been done on the claims, and good ore has been uncovered on different veins, samples from which have assayed as high as \$90 per ton in gold and copper. The ore on the most extensive showing averages about \$14 per ton. The adit to be extended into the Hibernia ground will tap the Viking's main vein at an approximate depth of 900 ft. The property is handy to transportation, being on one side of the Kettle river, and the Washington & Great Northern railway is on the other. A good bridge spans the river.—A drift is being driven on a vein, from two to three feet wide in the Globe mine. A good wagon-road will be built to the mine, and the former will afterward be equipped with machinery, and the company will then begin shipping ore. The mine is three miles distant from Orient, the nearest railway shipping point.

Republic, Aug. 26.

BRITISH COLUMBIA.

The inability of the Crow's Nest Pass collieries and coke plants to furnish an adequate supply of fuel to the Boundary and Rossland smelters, has caused a decided shortage in the output of those districts during the week ending August 17. The Rossland mines shipped and crushed ore as follows: Centre Star, 2,330 tons; Le Roi No. 2, 315 tons shipped and 700 tons milled; and the White Bear, 175 tons shipped and 350 tons milled. Total, 3,770 tons of ore treated.—The 12-drill compressor of the Iron Mask has been shipped to Phoenix to be used at the War Eagle group, which has recently been purchased by the Consolidated company. The Idaho shaft is down 40 ft. in pay-ore all the way, and on the Centre Star 1,100 level driving continues on the vein, which is six feet wide.—No ore was shipped from Le Roi, as there is not enough coke at Northport, and the smelter there is closed. Diamond-drilling continues on the Spitzee.—S. E. Griswold, manager of the Inland Empire, states that the hoist and pump will be running in a few days, when development at depth will be commenced.

The Trail smelter feels the coke shortage, and only half of the furnaces have been in operation. In addition to Rossland consignments, shipments were received during the week as follows: St. Eugene, Moyie, 535 tons; Whitewater, Ainsworth, 122; La Plata, Kokanee creek, 56; Standard, Silverton, 24; Westmount, New Denver, 23; Canadian group, Sandon, 22; Arlington, Erie, 22; Lorna Doone, Silverton, 22; Queen, Salmo, 22; Dunean, west fork of Kettle river, 17; Providence, Greenwood, 15, and Enterprise, 5 tons of ore.—The Northport smelter is being overhauled during the shut-down, and no ore was received during the week.—The Boundary mines shipped ore as follows: To Granby smelter from Granby mine, 16,773 tons. To B. C. Copper Co.'s smelter from Mother Lode, 5,977; from Snowshoe, 1,755 tons. To Dominion Copper Co.'s smelter from Brooklyn, 704; from Idaho, 1,280; from Rawhide, 2,940; from Sunset, 1,645; from Mountain Rose, 80 tons. To Trail smelter from Snowshoe, 1,655 tons. Total shipments for week, 32,809 tons, and for year to date, 744,151 tons.—Boundary smelters this week treated ore as follows: Granby smelter, 15,473; B. C. Copper Co.'s smelter, 9,471; Dominion Copper Co.'s smelter, 6,649 tons. Total treatment for week, 31,593 tons, and for year to date, 729,386 tons of ore.

The difficulty of getting coke is giving rise to a good deal of discussion in this district. The trouble seems to be largely due to the shortage of men at the collieries and coke ovens. Wages have risen in the metal mines, lumber camps, and harvest fields until they are higher than those paid for unskilled labor at Crow's Nest Pass, resulting in a

shortage of men there. Another cause is the shipping of coke to Montana for the smelters in that State. The managers of the local smelters consider that the home plants should be supplied first, and only the surplus shipped abroad.

MEXICO.

CHIHUAHUA.

The new 100-ton dry concentrating plant using the Sutton-Steele pneumatic process, is working at the Calera zinc mines, near Miñaca. C. M. Pringle is the general manager.—Manuel Gameros has purchased more silver-lead claims in the new Cerro Colorado district.—The output of the Dolores mines at San Isidro for July was \$90,000. W. H. Paul has succeeded in increasing the production since he took charge of the properties.—Some rich copper-silver ore has been struck about four hours' ride west of Chinipas, in the western part of the State. A shaft is down 150 ft. and work is progressing under the charge of E. A. Merriam.—A shipment of 300 cut turquoises was recently made from Chihuahua, the stones coming from the O. K. mine at Hornigas, near the K. C. M. & O. railroad. R. H. De Berque owns the property.—An order was recently received by all agents along the Mexican Central line, to the effect that no more zinc ore shipments for the United States were to be received, until further orders. This has caused great disquietude among the zinc producers, as their market is out of.—The railroad from Baca station on the Parral branch of the M. C. to the Cigarrera mine is completed.—The Resolana Mining Co. will build a 50-ton mill on its property, three miles from Santa Barbara. Peter Lee is president of the company and Luis Joseph treasurer.—It is rumored that the Montezuma Lead Co. may start up its concentrator at Santa Barbara in the near future. Several of the shareholders of the San Diego M. Co. have recently come from New York and Missouri to see the property. The deepest shaft is down 260 ft. A new gas-producer power-plant will be built. Nat P. Wilson is superintendent for the company.—After a long period of experimentation the concentrating plant of the Minas Tecolotes y Anexas, at Santa Barbara, is running steadily, and treated 13,600 tons of ore last month. About 800 men are employed.—The pumps in the Americana mine at Terrazas are raising 2,500 gal. water per min., and the water in the cave is being rapidly lowered.

By the execution of a judgment recently passed by the Supreme Court, the Don Jose Mining Co. is given possession of the mines at Gavalana. This is the first time for 27 years that all litigation has been cleared up, and the history of the mine is one long story of legal tangles, adverses, and difficulties.

GUERRERO.

The Mitchell Mining Co. is in receipt of wire advising it that the steamer bringing the rails for the La Ocha & Pacific railroad connecting its mines in Guerrero with the Pacific coast has arrived at Acapulco from Antwerp, and that the unloading at Port Marques was begun at once.

JALISCO.

Patrick Fitzgerald has been appointed general manager of the Santo Domingo mines in the Hostotipaquillo district, to succeed T. Elliott Smith, who resigned because of ill health. Nathan Udell is assayer for the company.—William Oliver, for several years general manager of the Agua Blanca mine of the Mexican I. & D. Co., in the Autlán district, has retired, becoming consulting engineer for the same company. Michael Minnehan succeeds him. The work of remodeling and enlarging the Agua Blanca concentrating plant is nearly finished. The concentrate will be freighted by wagons to Ameca.—Although the rainy season is on, in Autlán copper prospecting continues, especially in the Ayutla and Coapaxtle hills; in the latter, Emilio Leonarz, representing a German company, is developing the Princesa mine by a tunnel.—Thomas Kelly of Chicago has taken up a number of claims in the Ojo Verde district, through his representative, Frederick Ossolinski. If the Jalisco railway is extended as proposed, it will open up a promising copper country.

Special Correspondence.

Denver, Colorado.

The Card System at Telluride and Cripple Creek.—Labor Conditions.—Political Conditions.—Copper Ores in Colorado.

The announcement that the Smuggler-Union will abandon the card system, following, as it does, its abandonment by the Liberty Bell and the taking on of union miners by the latter company, has caused a buzz of comment in Telluride and throughout Colorado. The cause of the move is the present great difficulty in securing enough men. For a long time it has been difficult to obtain competent men; more lately it has been equally difficult to obtain any men at all. Most of the companies in Telluride have not, for this reason, lived up very strictly to the card system, so that the present move is more in the nature of a formal abandonment. Bulkley Wells announces that no union men will be employed, but, if, on the termination of the leases by which that property is now worked, the workings are again opened on company account, as is the general belief, it may prove difficult to adhere to this ruling.

In Cripple Creek, on the other hand, the card system is to be rigidly maintained and new notices to that effect are being posted throughout the district. Since the loss of the cyanide plant of the Golden Cycle Co. by fire, several properties that produce low-grade ores and enjoyed extremely low treatment rates at the Golden Cycle mill, have chosen to shut down until such time as the plant can be rebuilt rather than attempt to operate at smelter rates. This has given a temporary over-supply of labor in the district and the Mine Owners Association will probably find it easy to maintain its exclusion of members of the Western Federation of Miners, for some time at least.

A most promising property at Telluride is that of the Black Bear Co. This company is operating on what is regarded as an extension of the same vein that the Tomboy Gold Mines, Ltd., is exploiting and the showing so far made is highly encouraging. The workings are situated near the head of the cascade in Ingraham gulch, a wire-rope tramway to a point a little east of the Smuggler-Union mill serving for transport to the railroad level.

The political situation in the State does not at present offer much of interest, the guerrilla warfare which Judge Lindsay is waging against Governor Buchtel and the large corporate interests of the State figures most largely in the public attention. The Governor seems to find himself generally helpless to turn the tables upon his nimble adversary. Whether the statements made by the Judge are entirely true, there is certainly truth enough in them to call for some serious thought upon the part of all who believe in more than a merely republican form of government. With the coming of Utopia it may be possible to have a cleric and educator elected to the position of chief executive of the State, simply out of respect for the clerical and academic atmosphere and influence, but it seems scarcely possible that we have arrived that far yet. Those who object to being governed by, and in the interests of, corporate wealth, do not hesitate to deny that we have progressed so far. Be that as it may, Judge Lindsay has shown himself a sincere friend of, and unselfish worker for, the good of the raw material from which the commonwealth continually rebuilds itself, the boys and girls of the State. It is to be hoped that his influence, in this regard, at least, may never grow less.

The comparative slight importance of copper ore and copper smelting in Colorado must always be a source of

surprise when one regards their great importance in the States south, west, and north in the Cordilleras. In Colorado they are developed to so slight a degree that where copper ore is found, it must usually be shipped long distances for treatment, and this lack of smelting facilities has handicapped the development of many properties that might otherwise be paying mines. Possibly the development of the mineral resources of Routt county may aid in remedying this defect. Ex-governor Routt, for whom Routt county was named, and who was the first governor of the State of Colorado, was buried with State and municipal honors from the capitol on August 16, adding another to the list of pioneers who have gone to their long home. The romance of mining has largely fled; soon there will be none left to tell the tale of the early days to a more prosaic generation.

Butte, Montana.

Effect of Lower Price for Copper.—Lessening Production.—The Amalgamated Mines.—Butte Coalition.—Big Lode in the Rarus.—New Machinery.—The Snowstorm.

The falling price of copper will soon have an appreciable effect on the mining industry of Butte, for a low price of the metal will force many lessees and small mining companies to stop operations. Already the Bullwhacker company has ceased mining, because its ore, which averages only about 4% copper, is not rich enough to pay a profit at present prices. The smelters are also declining to purchase the lower-grade ores because of the uncertainty of the copper market. There also appears a tendency on the part of the large companies to curtail the copper output, and it would not be surprising if some of the large mines were closed and kept shut-down until the surplus copper is absorbed and there is a better tone in the copper market. The Never Sweat mine of the Anaconda Co. and the West Colusa mine of the Boston & Montana Co. have already been shut-down, though other causes than those indicated are given for this step. The prevalence of gas from a mysterious fire is given as the reason for the West Colusa suspension, and the machinists' strike is credited with the closing of the Never Sweat, the big engine at that mine being out of repair. It is surmised, however, that these apparent reasons are welcomed as an excuse for closing some of the mines. It is announced that as other engines break down, other mines will be closed. All labor about the mines and all kinds of supplies are costing more than they have in many years and it is apparent that the mining companies could make money by leaving the ore in the ground instead of storing copper on the surface. Labor conditions are not at all satisfactory in Butte, due to the strike of machinists and the action of the Western Federation of Miners in declaring void the contracts entered into by the miners and companies of Butte for a term of five years, by which the miners agreed to accept a sliding scale of wages, working for \$4 per day of eight hours while copper is at 18 cents or more per pound, and to return to the old wage of \$3.50 per day should copper prices drop below 18 cents. There seems to be a general impression that the miners will refuse to accept a reduction, notwithstanding their contracts, though the question has not yet been brought to an issue.

John Gillie, general manager of the Amalgamated properties, says that the Butte production of copper is about normal and the Amalgamated is working about the same number of men that it did last year. A great many more men are employed in the district, however, by the new companies. The latter cannot be expected to do much in the way of copper production for several

years yet, and in the meantime the demand for the metal is increasing. "I regard the present drop in price as temporary," said Mr. Gillie. "The big consumers of copper have refused to come into the market and are using up their regular stock. The reason for the drop in price is therefore apparent. But consider what the result will be when these concerns are again forced into the market. I believe we shall see copper soaring again shortly."

The North Butte Mining Co. is driving on the Edith May vein at the 1,800-ft. level and is cross-cutting for the Jessie at the same depth. The cross-cut north from the 1,600 is expected to reach the Berlin vein in a short time. No work is being done on the Berlin shaft. The North Butte continues to mine about 1,250 tons of ore per day, but it is probable that if the price of copper continues low that fewer tons of ore, but of a higher grade, will be mined by the company.—The Butte Coalition output runs between 1,300 and 1,400 tons per day. There is a rumor out that the company will soon begin active operations on the Alice group of mines, in which it owns a controlling interest. It is also reported that a big copper vein has been cut in the Magna Charta, one of the

station will be cut and an electric pump installed. The pump will throw 400 gal. per min. 1,000 ft. Some time ago the company experienced a great deal of trouble from the water, but it is now fully equipped for handling it.

Thomas L. Greenough, president of the Snowstorm Mining Co., says that the mill is handling 4,000 tons of ore per month. The mine is producing as much as can be treated at this time. Two hundred men are working in the mine. A new adit is being driven 500 ft. below No. 3, so as to give an additional depth of 500 ft. on the vein. It will be fully three months before the vein is reached by the new adit. The Snowstorm paid its last monthly dividend of \$40,000 on August 10.

Toronto, Canada.

Gold Finds.—Discovery on Montreal River.—Strike Situation Improving at Cobalt. — News of Operations. — Ore Shipments. — Another Smelter.

A rich gold find is reported near Night Hawk lake, situated west and slightly south of Lake Abitibi. Two Swedes are said to have discovered a vein of gold-bearing rock, 130 ft. wide, and to have traced it for two miles. There is a rush of prospectors from the neighboring settlements and camps. McDougall's Chute, 18 miles distant, has been deserted for the new field. While the first reports as to the extent and richness of the deposit are probably exaggerated, there is no doubt of the fact that gold has been found there. Samples of the ore have been forwarded to the Ontario Bureau of Mines, which show a quantity of visible free gold. The Bureau has also received official information as to the finding of gold at the headwaters of the Black river, a tributary of the Abitibi river. Willet G. Miller, Provincial Geologist, now in the northern region, will inspect these deposits shortly.

Another important gold discovery has been made some 80 miles up the Montreal river from Latchford, and near Fort Matachewan, a Hudson Bay port, on what is known as the South Bend of the river. W. H. Fletcher of Cobalt and Joseph L. Garvin of Ottawa, who have been prospecting there for some time, have discovered numerous large quartz veins, showing free-milling gold on the surface, and the party has staked out 15 claims. The value of the discovery is confirmed by J. T. Carmody of Cobalt, who has a wide experience in Arizona and South Africa, who has just inspected and reported on these locations. One of the veins when stripped measured 35 ft. in width and others from 4 to 8 feet.

Activity is gradually being resumed at Cobalt as the strike situation becomes less serious. The Western Federation of Miners is fighting the injunction lately secured by the Buffalo Mines Ltd. in the courts, and meanwhile the number out of employment becomes continually less, some returning to work on the employers' terms and others on the union scale. The Silver Leaf has accepted the union scale and resumed work. The Trotheway is taking out much first-class ore, a shipment of 20 tons to the Copper Cliff smelter having yielded \$29,000. They have also some 7,000 tons of low-grade ore on the dump.—The Kerr Lake (Jacobs) has started operations with a new air-compressor and drills, and bids fair to be a steady shipper. The Coniagas has secured nearly its full force and it is expected that the new concentrator will be working in a month.—Some good finds have been made at the O'Brien. A newly discovered vein has been stripped for 60 ft. and three small rich stringers, carrying ore as high as 1,000 oz. silver per ton, found running through wallrock, which is shot with silver to the width of three feet. Three other veins have been found, one very rich. There are 150 men at work.—At the Gillies

Montana.

Alice group, by a cross-cut from the Drummond claim. —Little work is being done on the Ophir mine by the Butte Central & Boston Co. and the output by lessees has been reduced lately. It had been the intention of the company to sink a deep shaft on the Ophir, but work on the shaft was stopped after it had been enlarged from a two to a three-compartment shaft some months ago.

One of the big veins of the Rarus mine, owned by the Coalition Co., has been opened at a depth of 1,800 ft., and will soon be in shape for an increased production. The vein was opened by a cross-cut driven 200 ft. from the shaft.—The shaft of the Alex Scott mine is now 1,000 ft. deep. Sinking was stopped several weeks ago and the efforts of the company were directed to exploratory work on the 600, 800, and 900-ft. levels in the hope of striking a good orebody and taking out enough ore to make up a portion of the sum due on the bond. However, no big body of ore was found, and the promoters of the company had to do some remarkable hustling to raise the money with which to pay off the bond, succeeding in doing so just an hour before the expiration of the time. The limited quantity of ore, that has so far been found as yet, has been in pockets.—The new air-compressor purchased by the Colusa-Leonard Extension Co. has been installed and is at work. The shaft has reached a depth of nearly 800 ft. At the latter point a

Limit, the mine of the Ontario Government, the shaft is down 115 ft. and driving to the extent of 210 ft. has been done at the 65-ft. level.—Steady progress in development is being made at the Cobalt Lake mine. The north shaft is down 12 ft. The level station in shaft No. 4 has been blasted out and sinking continued to 92 ft. A level station has been dug out at shaft No. 5 at a depth of 95 ft. and driving begun.—Several new companies, of which little has hitherto been heard, have been doing extensive development work and promise to figure shortly on the list of shipping mines. Among them are the Stratheona, on which some recent strikes promise well, and the American Silver King, where a vein from 3 to 5 ft. wide has been stripped for 200 ft., assays varying from 900 to 1,200 oz. silver per ton.

Shipments of ore from Cobalt for the week ending August 17 amounted to 259 tons, contributed by the following mines: Buffalo, 30 tons; La Rose, 21; Nipissing, 148; Temiskaming, 59 tons of ore.

Considerable excitement has been occasioned during the last few days by an apparently well authenticated statement that the Salt Lake Smelting & Refining Co. intends to erect a large smelter at North Cobalt to cost at least \$2,000,000 with a capacity of 250 tons per day. Charles H. Gage, chief consulting engineer of the Salt Lake Co., was looking over the ground this week.

Mexico City.

Effect of the Railroad Merger.—Car Shortage.—Big Raise in Freight Rates.—Serious Blow to Mining Industry.—Figures that Tell the Story.

Is the great merger of the main lines of Mexico into one large company to be controlled by the Federal Government going to be as great a benefit to the country at large as was promised? Or is it going to be run by other monopolies and take advantage of the general public by reason of there being no competition? And is the guaranteed interest on the bonds to be paid by a general raise on all freight rates? These are the questions that are being asked throughout the Republic of Mexico today, by reason of a general revision of the freight rates on all the lines that are included in the consolidation. The first move was an order increasing the minimum weight for a carload from 10,000 kg. (or 22,000 lb.) to 15,000 kg. (or 33,000 lb.). It was claimed that this was made necessary by reason of the great call for cars and the requirement that they be loaded nearer to their capacities. Be that as it may, it will certainly work considerable hardship on the shipper, who formerly got carload rates on 10,000-kg. loads, but will now have to pay local rates because of his not having the requisite 15,000 kg., and had the railroads any kind of management there would not be such a scarcity of cars. I know of one case of a shipper asking for a week for his goods only to be told by the agent that they had not arrived until finally he learned that the car had been in the railroad yards all the time, and of another case of a car being switched around wild to various concerns for a month before the correct person found his car, although said car was plainly and properly billed.

This increase, however, in the minimum carload weights will not work a material hardship on the miner in general, for his shipments will usually exceed 15,000 kg., but the blow that strikes at the very heart of the mining interest is the new tariff rates on ore, as given out by the railroads mentioned, the principal of which are the Mexican National and Mexican Central railroads, and which rates have been presented to the Federal Tariff Commission

for consideration and approval. The increase in these rates over the old is tremendous and unprecedented, and though they have not as yet been approved, the railroads are urging their approval with all possible insistence, and it behooves all who are interested in the mining business in Mexico to use their utmost effort and influence to prevent the adoption of such rates. In the first place the shipper is no longer allowed to run his own risk of loss and put a valuation of P25 per ton on his ore, but the new rates require an actual valuation according to smelter returns, without freight reduction, and according to this valuation he is given three classifications; the first class being ore worth over P50 per metric ton; the second class, ore of a value between P50 and P25 per metric ton; and the third class, the ore under a P25 valuation.

Formerly practically everything was shipped at P25 release valuation, the shipper being willing to take the risk, but that is to be no longer allowed under the new rates, and the ores of higher value must pay more. Yet does it cost more to haul them?

Space, of course, will not permit of a complete tabulation of the new rates, but an idea of the change made may be obtained by giving a few examples from some of the principal shipping points to the Aguascalientes plant of the American Smelting & Refining Co. and the Torreon plant of the Torreon Metallurgical Co., as follows: From Pachuca to Aguascalientes, a distance of 576 km., old rates in pesos, 5.12; new rates, 3d class, 5.97; 2d class, 7.44; 1st class, 9.36. Pachuca to Torreon, 1,127 km., old rates, 7.58; new rates, 3d class, 7.96; 2d class, 10.05; 1st class, 12.82. From Marfil (the Guanajuato shipping point) to Aguascalientes, 221 km., old rates, 2.75; new rates, 3d class, 3.80; 2d class, 4.59; 1st class, 5.67. Marfil to Torreon, 772 km., old rates, 6.20; new rates, 3d class, 6.83; 2d class, 8.53; 1st class, 10.88. From Parral to Aguascalientes, 879 km., old rates, 8.54; new rates, 9.60, 11.38, and 13.68, according to class. Parral to Torreon, 328 km., old rates, 5.12; new rates, 6.63, 7.46, and 8.71 according to class. While from Chihuahua, whence ore is shipped to Aguascalientes, Torreon, Monterrey, and El Paso, the changes are as follows: To Aguascalientes, old rates, in pesos, 7.17; new rates, 7.70, 9.63, and 12.36; to Torreon, old rates, 4.51; new rates, 5.47, 6.76, and 8.48; to El Paso, old rates, 3.74; new rates, 4.81, 5.88, and 7.38; to Monterrey, old rates, 6.51; new rates, 8.47, 3.76, and 10.48 for 3d, 2d, and 1st classes respectively. It will be seen from the above that these increases run from about 10 or 15% as a minimum to over 100% (see Marfil to Aguascalientes, 1st class) and it is estimated that the increase in freights on ores, based on shipments to smelters during the last twelve months, will be close to 50%, or between 3,000,000 and 4,000,000 pesos in a single year, which the mines will have to stand for the benefit of the railroad. Some of the large shippers will have their freight bills increased by over P1,000 per day. It will react greatly and seriously upon the mining industry throughout the Republic, many properties may have to close down, a great deal of low-grade ore will be cut off, and the chances are that what the railroads hope to gain in rates they will lose in tonnage. This has really been sprung on the public so suddenly (and is not generally known even now) that time has not been given for concerted action among the mining companies, but it is to be hoped that important shippers will take some strong and immediate individual action. The President of the Tariff Commission, who has the same under consideration, is Lic. Don Luis Mendez, First Calle de Damas No. 1, Mexico City. No one who has any influence to prevent the approval of these new rates should fail to use it.

London.

Our Correspondent Waxes Poetic.—Processes and the Zinc Corporation.—West African Output.—Mexican Coal Enterprise.—Cornish Tin Ticketing.—Methods of Ore Treatment.—A Touch of Humor.—Depreciation in Mining Shares.

"Welcome, welcome with one voice;
In your welfare we rejoice,
Sons and brothers, that have sent,
From isle and cape and continent,
Produce of your field and flood,
Mount and mine, and primal wood,
Works of subtle brain and hand,
And splendors of the Morning Land
Gifts from every British zone!
Britons hold your own!"

Thus sang the immortal Tennyson in the ode composed by him for the ceremony at the opening of the Colonial Exhibition at South Kensington by her late majesty the Queen. To your correspondent—still conscious after the lapse of twenty-one years of the thrill of that memorable scene when he assisted in making vocal those stirring words—the indictment against "old John Bull," anent the Royal School of Mines, from "That young eagle of the West" (the ode again!) comes with something like a shock. From the standpoint of the good old crusted heroes and the somnolent South Kensington notabilities of mid-Victorian lustre (on the governing body of the new College), the views expressed in the MINING AND SCIENTIFIC PRESS of July 27 must seem rank heresy. None the less they are undoubtedly shared by many people on this side whose opinion is of consequence.

It seems after all that the Cattermole process is not to be the salvation of the Zinc Corporation, but the Elmore oil process. At the recent meeting of stockholders in London, Mr. H. C. Hoover explained that when he arrived at Broken Hill last March it became very evident that the only reliable flotative agent was a mixture of acid and oil. Mr. Queneau's process was acid pure and simple. They then had in front of them two methods—one was the Cattermole process and the other was a machine invented by Messrs. Elmore, which had been largely used in copper mining, but had not been tried on a practical scale in the case of zinc. The plant was altered to adopt that, and at the same time a unit of the Elmore machine was obtained to see if that would give better results. Mr. Hoover said the Cattermole process has not been a commercial success so far, but that is more a question of the quality of the tailing which is available for the present plant than it is of the process itself. If they had available for this old plant (Mr. Queneau's plant) the richer tailing, such as is being treated by the Sulphide Corporation, they too would be earning profits today by that process. Unfortunately the tailing at the British mine is of lower grade. They were anxious to work out their process on the lowest grade position. The Cattermole and the Elmore are not separate processes. So far as the Zinc Corporation Co.'s position goes, the processes are identical. The only difference between them is the different manner in which the concentrate is trapped after being floated. Messrs. Elmore, working largely on copper, have invented a machine that appears to be the solution of the difficulty.

The Elmore results obtained had been very good, and if these results are applied to the Zinc Corporation's tailing, they will be making a profit of from 8 to 10s. per ton. Between 800,000 and 1,000,000 tons of tailing were already paid for and they had available under the options somewhere between 3,000,000 and 1,000,000 tons more. This tailing contains an average of about £5 per ton of gross value in the shape of metal, and there was an enor-

mous margin between that and the present working costs, which are practically £4 12s. 0d. out of the £5. The resolutions for the reconstitution of the capital were carried by a large majority. The 500,000 old shares will be called Ordinary and there is to be an issue of 180,000 Preference Shares. The £1 Ordinary Share has gone down to the "nimble bob," but is now rather better, and a more hopeful feeling prevails as to the ultimate success of the Corporation.

The West African gold output returns for last month were 22,498 oz., as compared with 16,070 oz. for July of last year, an increase of 6,428 oz., while the output for the first seven months of the year is 166,582 oz., or 46,741 oz. ahead of the figures for the corresponding period of 1906.

The directors of the Mexican Mining & Industrial Corporation (floated in the early summer under the auspices of the Venture Corporation) announce that they have secured an option on the Sabinas colliery situated in the valley of the Sabinas river, in Coahuila, Mexico. The circular states that this option having been secured, they will be enabled to proceed with the flotation of Sabinas toward the end of the autumn of the current year, and the directors anticipate that the operation will be successfully carried through with highly favorable results to the Corporation. It appears that the Sabinas colliery is a going concern with a business earning at present about £5,000 per month with a steadily increasing output amounting at present to 22,000 tons per month, and enormous reserves of coal are said to be already opened up.

A notice has appeared in the press that the Lena Goldfields will be floated by the Russian Mining Corporation in the autumn. This refers to the property of the Lena Gold Mining Co. of Petersburg in Eastern Siberia, north of Lake Baikal, recently visited by C. M. Rolker. It is understood that Mr. Rolker's report is of a highly satisfactory character.

The first Cornish tin ticketing for August is rather disappointing. A lower average price was realized than for the previous sale, and Doleath offered only 65 tons. The home parcels amounted to 200 tons, which fetched £21,020 10s. 0d.—an average of £104 16s. 9d. Thirty-two tons of Swaziland tin totaled a sum of £3,713.

At a friendly meeting of interested parties held lately at North Crofty, Mr. Marcus Rutherford, an American metallurgical chemist, described the system that he has adopted for the treatment of the ores of North Crofty, as follows: Roller-crushing instead of stamps, screening after each machine, and the crushing is done dry. The crushed and sized ore is calcined for elimination of sulphur and arsenic. It then goes to the separating machines where all of the metalliferous values are removed, leaving a final discard of quartz and gangue. This complex concentrate contains iron, copper, tin, and zinc, and is smelted, slagging the iron and producing a bronze containing the tin, copper, and zinc. These ingredients may not be in the required proportions to make the desired alloy. This is rectified by adding whatever there may be lacking; in other words, standardizing the alloy. Recovering all of the metals permits of working an ore that is too low-grade to work for any one metal. Under existing methods the Cornish miner not only loses all of the metals other than the one for which he is dressing, but also loses a good proportion of the particular metal in his attempt to get it pure.

After he has dressed an ore for tin and lost all of his copper and zinc—and part of his tin; and another man dressing for copper has lost all of his tin and zinc and part of his copper, and the man dressing for zinc has done the same, these various pure metals come to the brass or

bronze founder and are mixed again to make brass or bronze. In responding to the toast of 'Success to Cornish Mining' one of the guests told, amid laughter, of his experiences on returning from South Africa. He went to one mine and said to the captain: "Why don't you pull out these old heads and install good Californian stamps?" The answer he got was to the effect that if they crushed the stuff too quickly they would work out the mine in a few years—which wouldn't do! He (the guest) recommended the adoption of the South African miner's attitude: "When a mine was worth working, work her for all she's worth, and when she's good for nothing, scath her and look for another."

More depreciation of mining stock! The monthly table of comparative values of Australasian mining securities given in the *Australasian World* shows a greater shrinkage in aggregate values than on any previous occasion. A year ago the 34 representative mines included in the table were valued by the market at £32,353,095; but at the mid-August settlement their values had fallen to £28,851,686. Compared with the values at the beginning of the year, when they aggregated £34,625,830, the fall is still more severe; and during the past month alone the depreciation amounts to £1,405,188. Between July 10 and August 12, 21 properties depreciated and six appreciated in value, while seven remained stationary. Among the few increases the largest were Talisman Consolidated (£159,375) and Oroya Brownhill (£112,500). The principal decreases were: Kalgurli, £390,000; Mount Lyell, £325,000; Broken Hill Proprietary, £180,000; British Broken Hill, £131,250; Mount Morgan, £125,000; and Waihi, £93,750.

Salt Lake, Utah.

Dividends.—Consolidation at Mercur.—Heinze at Park City.—Ore Shipments.—Scarcity of Coal.—Shipments From Tintic.

Dividends were paid by Utah mines during August to the amount of \$580,350, the contributing mines and amounts being: Newhouse Mines & Smelters, \$300,000; Colorado, \$120,000; Gemini, \$50,000; Lower Mammoth \$14,500; May Day, \$8,000; Uncle Sam Consolidated, \$10,000; Grand Central, \$12,500; Beck Tunnel Consolidated, \$40,000; Utah, \$3,000; Bingham-New Haven \$22,600.

The Northern Light, Columbia, and Chloride Point mines in the Camp Floyd, or Mercur district, are likely to be consolidated. Special shareholders' meetings of the first two named companies have been called to consider the proposal early next month. It is proposed to take in the Chloride Point by purchase, the price being \$20,000, and form a new organization to be known as the Lion Hill Consolidated Mining Co. The Chloride Point has produced considerable silver ore and has been a dividend-payer.—John Dern, president of the Consolidated Mercur Gold Mines Co., has expressed himself as being eminently pleased with the results achieved by the new slime-plant recently installed at the Mercur mine and states that fully one-half of the loss in the tailing is now being recovered. The last of the equipment has arrived and it is a matter of only a short time until the capacity will be raised to 600 tons daily.

F. Augustus Heinze, who has held an option on a controlling interest in the Silver King Coalition at Park City, has allowed it to lapse. A payment of \$5 per share on a large block of the stock was due on August 15, and on another block on the basis of \$7.50 on October 15. It is believed that negotiations will be re-opened and that the tightness of the Eastern money market has had something to do with the blocking of the deal.

Jesse Knight of Provo has acquired a controlling interest in the Treasure Hill mine at Park City and in compliance with his option has paid \$45,000 into the treasury of the company. Preparations are being made to start vigorous development. A deal is pending for the acquisition of the Creole mine, in which event the Treasure Hill property would be worked through the Creole shaft.—An electric-haulage system is being installed at the Daly-Judge mine at Park City. Recent developments in the mine have been of a very satisfactory character and some recent alterations in the mill have been productive of better results.—The ore shipments from Park City last week amounted to 1,767 tons, the contributing mines and amounts being: Silver King Coalition, 775; Daly-Judge, 293; Little Bell, 49; Daly West, 650 tons.

The Gold Chain Mining Co., with headquarters at Provo, Utah, has filed articles of incorporation to develop and operate the Gold Coin group in the Tintic district.

Utah.

E. E. Loose, of Provo, is president of the organization. —There appears to be no imminent danger of labor difficulties at Tintic. A statement has been made by the president of the miners' union that the miners are content with the present wage scale.

The fuel situation in Utah at the present time is anything but satisfactory. Mining and smelting companies have found it almost impossible to get coal for storage, and consequently the probability of a famine during the winter appears inevitable. The price of domestic coal in Salt Lake City has advanced from \$5.25, the schedule for lump and nut coal last winter, to \$6 and \$6.50 per ton, and dealers are several weeks behind in their deliveries.

The ore and bullion settlements reported last week in Salt Lake totaled \$724,000, while sales on the Salt Lake Stock & Mining Exchange during the same period amounted to 321,732 shares, for which \$267,884 was paid.—Ore shipments from the Tintic district during the past week aggregated 144 carloads, the contributing mines and amounts being: Ajax, 3; Beck Tunnel Consolidated, 9; Bullion Beck, 3; Colorado, 7; Centennial Eureka, 48; Eagle & Blue Bell, 4; Eureka Hill, 2; Grand Central, 5; Godiva, 2; Lower Mammoth, 2; Mammoth, 14; May Day, 7; Scranton, 6; Uncle Sam Consolidated, 6; Victoria, 3; Yankee Con., 4; other mines, 4 carloads.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE electric locomotive has not been much employed in mines in the United Kingdom, but is largely employed both underground and on the surface in America and on the Continent, and in gold mines in New Zealand.

FROM a financial point of view it is essential for profitable hydraulic mining that there should be ample facilities for grade and dump, and a sufficient head and an abundant supply of cheap water; the importance of each of these requirements varies inversely with the richness and extent of the gravel.

THERE are three general forms of water engines: The water wheel proper, such as the overshot or undershot types; the turbine; and the engines typified by the Pelton wheel, which may be considered as between the large water wheel and the turbine. In this classification, the large water wheel and the water turbine correspond roughly to the low-speed and high-speed steam engines.

THE percentage of opening in a screen is the ratio of the net area of the holes to the whole area of the screening surface. This depends upon the arrangement of the holes and the amount of space left between them, and the greater the percentage of opening, the more rapid and perfect will be the screening; but the practical limit is set by the inadvisability of impairing the strength of the screen.

CLASSIFIERS are devices for subjecting sand or slime to the action of water under free settling conditions, with the object either of obtaining a series of products diminishing in size, preparatory to subsequent treatment, or to settle the whole material as completely as possible from the water. They all have a carrying current of water that carries forward whatever grains may remain suspended, and some have rising hydraulic, or clear water currents, added from below.

THE materials used in a structure usually do not conform to our assumption as to the strength and properties of those materials. In many cases the materials, as actually used, are not so strong as we are led to believe by the application of the tests described in certain textbooks. There is no definite value that can be stated as the strength of a particular kind of material without many reservations, and many more reservations than can be conveyed in the ordinary books of reference.

ORE is weighed in tons of 2,000 lb. each in the United States, and bullion is weighed in troy ounces. In assaying, the assay ton system has been generally adopted, based on the proportionate weight of one ounce troy to one ton avoirdupois. By expressing the number of troy ounces in a ton in milligrams we have a weight containing 29,166 milligrams, which is called an assay ton. Therefore, if one assay ton of ore is used in the assay, every milligram of metal extracted from it will represent one ounce troy per ton of 2,000 pounds.

IN Colorado, molybdenite occurs only at or above timber-line, and as a rule disseminated through the country-rock in spots or bands, also in pockets, but seldom in real veins. As the ore is always of low grade and found at high altitudes, concentration is generally best effected at the mine. The concentrate may then be treated chemically and marketed as ammonium molyb-

date or molybdenum dioxide, of a blue color, or as the trioxide. When chemically pure and free from ammonia this sells at \$2 per lb., and metallic molybdenum brings 40c. per grain.

CAST IRON is, generically, iron containing so much carbon or its equivalent that it is not malleable at any temperature. Specifically, cast iron is iron in the form of castings other than pigs, or remelted cast iron suitable for running into such castings, as distinguished from pig iron. For instance, cast iron pigs, or pig iron, is remelted and cast into castings, such as columns, locks, gears, etc., of special shape suited to their special purpose; these are specifically called cast iron, and this is the usual restricted meaning of cast iron in trade language. It has been recommended to draw the line between cast iron and steel at 2.2% carbon for the reason that this appears to be the critical percentage of carbon. In Germany every metallic product of the blast-furnace is called pig iron or cast iron.

SULPHUR deposits of value occur in the State of Louisiana. Great difficulty was at first experienced in dealing with these deposits, which occur at a depth of between 600 ft. and 800 ft. below the surface, by reason of the fact that the over-laying strata contained quicksand. The beds have been ascertained to be between 100 ft. and 200 ft. thick and extend for many miles underground. They are now being mined by means of steam and compressed air. Borings are driven into the stratum of sulphur, and a steam pipe leads down to the bottom of the bore. Steam is then forced down the pipe, and the melted sulphur is brought to the surface by a compressed air lift-pump system. At the surface it is discharged into large concrete-faced shallow vats or pools, where it is allowed to solidify, after which it is broken up and shipped to the refinery or direct to the market.

LIQUID AIR was first used as an explosive only in combination with other substances. It is now used alone, its explosive power depending upon its property of turning suddenly into vapor at an elevated temperature. If the vessel in which the liquid air is contained is sufficiently tight, very high expansive powers are attained. For this reason it is stored in vessels having a small opening. This property of the liquid air makes it necessary to place the cartridge in place in the rock before it is loaded. In English mines the cartridges are made of thick phosphor-bronze, the loading being calculated so that the pressure reaches 5.6 kg. per sq. cm. The explosion takes place in six or eight minutes after loading and about 30 tons of coal are broken by one shot. The coal falls in blocks about 60 cm. in circumference. A heavier loading of the cartridge causes the coal to be broken into powder.

BARYTES occurs commonly in veins as a gangue of metallic ores, and also in veins in sandstone and limestone, or as a replacement of limestone. Differential weathering of the limestone and barytes has given rise to deposits of barytes embedded in residual clay. It thus may have a wide range in geologic age and an extensive distribution. The principal sources, however, are limited to two districts—that of Missouri and the Appalachians. In Missouri the counties of Washington, St. Francois, Crawford, Cole, and Miller are producers, Washington county furnishing three-fourths of the output of the State. The Appalachian district includes contiguous portions of Virginia, Tennessee, and North Carolina. Barytes has been found also in the Cumberland valley in southern Pennsylvania, although but little has been produced there.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

The Royal School of Mines.

The Editor:

Sir—Mr. Garrison's letter protesting against the extinction of the Royal School of Mines, published in your issue of July 27, requires an answer. He is mistaken in assuming that the School is to be abolished because of its affiliation with the newly formed Imperial College of Science and Technology. Under the charter the School maintains its name and its diploma and remains a separate institution, as much as it did when affiliated to the Royal College of Science. The new arrangement has the support of the Institution of Mining & Metallurgy, which includes numbers of old students of the Royal School of Mines among its members; indeed, it is largely due to the efforts of the Institution that the new arrangement, which it is hoped will improve the education given by this famous school, has been brought about.

W. FISCHER WILKINSON.

New York, August 15.

[Mr. Garrison understands the new plan. Like the editor and other graduates he would prefer to have a first class funeral for the old School of Mines than see it made a part of an Imperial scheme with a parochial endowment and a kindergarten annex. The efforts of the Institution are cordially appreciated, but they have been largely neutralized by the inertia of British red tape and the inherited incubus of South Kensington. Incidentally it is amusing to see an editorial article on mining education in the *Mining World*, a Chicago periodical, in the course of which reference is made to "British home and colonial colleges" that are supposed to train mining engineers. Camborne, Ballarat, Johannesburg, and Otago, are mentioned, but the Royal School of Mines gets no recognition. Is it the ignorance of the man at Chicago, or is the R. S. M. no longer worthy of mention?—Editor.]

Erosion and Oxidation in Sonora.

The Editor:

Sir—The suggestive address by H. V. Winchell, printed in your issue of July 13, and the stimulating editorial in the following issue, have led the writer to consider how far some of the theories set forth coincide with his observations.

As the discussion has referred to hot and arid regions, a few words on northern Sonora may be of interest. For several months the writer has been in the southern part of the Magdalena district where mineral veins and ore deposits are very numerous, although there are no deep mines. Here both oxidized ores and sulphides are found at many points. The zone of oxidation in some properties has been opened to a depth of 300 ft. or more, while in others sulphides occur within 20 to 40 ft. of the surface. The conclusion reached by the writer with reference to this variation is that in general erosion keeps pace with oxidation where the surface slopes are abrupt. Where they are gentle, or nearly flat, oxidation is deep. It would not be true, in Sonora, to say that oxidation is more noticeable in advance of erosion on the warmer slopes of the mountains. Here the south and west slopes, which endure the higher temperature by day, are subjected to a greater contrast of low temperature at night and so to greater strains and resultant disintegration.

Without doubt, oxidation must progress more rapidly in Sonora than in a colder region, but with the oxidation of

the sulphides and the alteration of the metalliferous minerals, that of the country rock also occurs and thus aids erosion. Further, the character of the enclosing rock bears an important relation to the progress of oxidation. A hard massive quartz will carry iron pyrite and galena unaltered at the surface, because the quartz is relatively impervious to water. A limestone baked and hardened by volcanic intrusions may also hold galena or pyrite unaltered at the surface. Again, oxidation may be prevented by the retention of the ground water in the rocks through the obstruction of their natural drainage by volcanic dikes.

Since all explanations of natural phenomena become more complex as more facts are recorded, we may expect that a complex explanation will be necessary to state the varying relations of oxidation and erosion. But whatever variations in opinion may come through increase of information, we most fully acknowledge our obligation to the pioneers in thought who supply us with foundation to work on.

F. J. H. MERRILL.

Llano, Sonora, Mexico, August 18.

Concentration of Slime.

The Editor:

Sir—I have been engaged for a number of years in milling, amalgamating, and concentrating California gold ores; and have made a careful study of the losses encountered, and methods for concentrating, and recovering, a part of them on canvas tables and other appliances. Thinking that perhaps a discussion on this topic might be interesting to a part of your readers, I submit the following:

California gold ores are mostly crushed to pass screens having from 20 to 40 openings to the linear inch. They are amalgamated on copper plates, with a subsequent careful concentration on vanners. This latter treatment practically recovers all of the metalliferous particles that would be retained on a sieve having 150 openings per linear inch. In order to make a further concentration of the finer particles, it is necessary to size and eliminate the coarser particles of waste. This is usually effected in a crude way, by passing the tailing through variously, and often wonderfully constructed, apparatus, called hydraulic sizers. In some of the installations that I have seen, the pulp passes through a complex series of these devices and still discharges muddy water with the coarse sand and carries over large particles of waste with the slime for treatment on the canvas plates.

Classification is of prime importance, if a good recovery is to be obtained on canvas; and in my opinion the best cone-sizers to be obtained on the market should be installed, instead of wasting time and money with make-shifts. Now having crudely eliminated the principal part of the waste oversize particles, there is diversity of opinions as to whether the tailing should be still (1) further separated into two or more grades of material, and each different grade given a careful treatment on properly adjusted canvas tables; or (2) whether it should be first treated as it is and then resized and the finer particles given another treatment on a differently adjusted canvas plant. I am an advocate of the second method of treatment; for the reason that fine slime does not greatly interfere with the collection of the coarse particles of mineral; but the coarser particles of waste do interfere seriously with the concentration of the finer particles of mineral.

Various plants with which I am acquainted are only recovering about from 15 to 20% of the mill losses, employing the first method; while I once constructed and

operated a plant on the second plan that effected a recovery of nearly 50% of the mill-losses. In the plant that I installed and operated I first treated the tailing as it came from a 20-stamp mill by a sluice system over cloth of twilled drilling with a distribution of about one foot per stamp, and a flow of 12 ft. This was to collect a part of the oversize particles of mineral that normally should have been saved on the vanners. I then sized out the coarse particles of waste with a crude hydraulic sizer and treated the pulp again on a sluice system with four times the original spread, or width of distribution; after which I sized out practically all of the sand of a size to be retained on a 120-mesh sieve, then treated the pulp on wide tables of the Gates style with six times the original spread, or distribution.

In this case the canvas-concentrate was rich enough for direct chlorination treatment without re cleaning. If it had been necessary to re clean the canvas-sweeps on vanners my percentage of recovery would unquestionably have been lowered. But I claim that it would still have greatly exceeded the recovery usually obtained by the plants that practise classification into a series of different grades and then give each grade a single treatment, for the reason that many of the finer particles of mineral that are associated with the coarse sand are displaced from their lodgment on the canvas by the action of the heavier particles of waste, so as to be carried away and lost. One of the principal arguments advanced by the men who first separate into different grades before canvas treatment, is that it is necessary to have the material separated into grades for re cleaning on vanners because it is necessary to have the vanners adjusted to a different speed and throw for treating different sized particles of mineral. I agree with them thoroughly in this proposition; but why cannot the canvas-concentrate be treated on the vanners in the same way as I advocate for the first treatment on canvas, namely, treat all the pulp on vanners adjusted to save the coarse particles of mineral; then size out, and eliminate, the coarse particles of waste, and then reconcentrate the fine particles on suitably adjusted vanners. Of course the material should be passed through dewatering cones as it is essential for good vanner work on all grades of material, to have the pulp of the right fluid consistence.

Perle T. Hambric, who is at present operating a canvas-plant at the Central Eureka mine, has recently invented and applied for patent on an automatic plant that will probably revolutionize canvas concentration, and lead to its introduction and use in cold countries. This device is designed on the lines of a merry-go-round with the tables constructed in tiers around the periphery. Mr. Hambric says that he can design and construct the plant of structural steel to carry ten decks of canvas tables, one above the other, and in this way erect a plant of a capacity for handling the pulp from a 100-stamp mill, and house it in a building 40 ft. square. The machine is adjusted to revolve slowly around a central axis and at a certain point in the revolution the pulp is cut off and the accumulated concentrate removed, to be saved by means of a system of spray-pipe. The plant is entirely automatic and requires no attention, except to change the canvas every few months and see that the spray-pipes and pulp-distributors do not become clogged so as to interfere with the operation of the plant. Some ores carry quite a lot of valuable mineral that either occurs naturally in a state of slime in the ore, or is ground to so fine a state during the crushing operation that it cannot be collected on an ordinary canvas plant, but will remain in suspension in still water for hours. In some instances this suspended mineral possesses some adhesive quality that causes it to adhere together and accumulate on suit-

able surfaces, if the muddy water from which all of the fine sand has been eliminated is allowed to circulate slowly through a tank or reservoir filled with pieces of lumber, or other collecting surfaces, set at such an angle as to allow the non-adhesive particles of gangue to slide off by reason of their gravity. At one mine I was able to collect a lot of this valuable material by passing the muddy water below the canvas plant through a tank filled with pieces of lumber fixed on an inclination of about 50 or 60°. The fine suspended mineral would collect and build up as a slimy product of about the consistence of vaseline, and assaying \$150 per ton.

It is well known that mineral oils have an affinity, or attraction, for fine gold, and many of its associated minerals. If a fine particle of free gold, amalgam, or mineral carrying gold becomes coated with a film of oil, and does not possess sufficient specific gravity to be concentrated, it will probably float on the water. If the film of oil be thick enough, it will rise and float on the surface; but my observation has been that, while such a tailing always shows slight films of oil that carry small quantities of valuable mineral, the proportion of it is infinitesimal in comparison with the suspended mineral that simply floats on the water.

Allowing that it is oil, the question arises as to the source from which the oil emanates. In my opinion the oil may be derived from the following sources: First, mineral oil used as lubricants on drills, cars, skips, hoisting-cables, rock-breakers; and on the guides and cams around the batteries. Second, vegetable oil derived from crushing chips in the mortar. The latter is the more important.

This floating mineral often comprises over one-half of the mill-loss; and while a part of it can be recovered by proper appliances, I believe that the better plan would be to avoid making the greater part of it, by studying the cause and devising means for milling the ore in such a way as to prevent its formation. In my opinion this could be most readily accomplished by successive crushing followed in both operations by amalgamation and concentration. The wood and oils would be eliminated at the first operation, leaving only the coarse clean particles of ore for the final fine crushing, which I think should probably be effected in a tube-mill.

WILTON E. DARROW.

Sutter Creek, Cal., August 20.

NICKEL IN ALASKA.—At two points on the shores of Prince William sound there has been prospecting for nickel. One occurrence is in small stringers along the south side of Port Valdez, and the other is near the mouth of Miners river, on the east side of Unakwik bay. The country rock is diorite, carrying disseminated pyrrhotite. The vein, if it can be so called, is a zone in the diorite impregnated with this iron sulphide, and has no sharply defined walls. This sulphide-bearing rock is 10 ft. or more wide, and above the tunnel, which is at the water's edge, a zone of iron-stained rock, perhaps 20 ft. wide, can be seen running up the cliff. Here also there are in the diorite some pegmatite veins, which carry pyrrhotite. These veins resemble those north of Mummy bay on Knight island. They are from $\frac{1}{4}$ to 2 in. wide, and are not sharply defined. There are also in the dioritic country rock small fractures filled with quartz, but these do not, at least so far as seen, carry the iron sulphide. It was thought that the pyrrhotite carried considerable nickel, and also cobalt, but selected samples of the best ore which could be found at this point were assayed, and the results showed neither cobalt nor nickel.

Opening of the New Mining Building of the University of California.

On August 23 the Hearst Memorial Building, given to the University of California by Mrs. Phebe Hearst, was opened with appropriate ceremony. These new quarters for the mining department of the University represent a memorial to George Hearst, former senator from California and a mine operator famous in the story of Western development. The money for the building (which has cost thus far \$550,000) is supposed to come from the dividends paid by the Homestake mine, in South Dakota, one of the great ore deposits the exploitation of which was undertaken by James B. Haggin and George Hearst, who were associated in many successful enterprises. Mr. Haggin is still alive, a veteran, but an active figure in the mining world. Another famous mine and the one that laid the foundations of the Hearst fortune was the Ontario, in Utah, which was only a prospect in 1872 when George Hearst examined it, deciding that "the vein had all the marks of a thoroughbred." To make the purchase, he drew on his associates in San Francisco for \$32,500, and it is said that they hesitated, having been unfortunate in some other mining deals, but they finally decided to back the judgment of Hearst—how successfully we all know now, for the Ontario has produced \$36,000,000 and has paid \$15,000,000 in dividends. The new Mining Building is worthy of the Homestake, the Ontario, and other great mines that have paid tribute to the erection of it. It is also worthy of the splendid group of buildings destined to adorn the campus of the University. The material is granite, the fine-grained white variety quarried at Raymond, on the edge of the Yosemite valley. Seen at a distance it looks like marble, but it is more enduring.

Mrs. Hearst was present, also Mr. William R. Hearst, his wife, and their little son. In the gathering, besides the faculty and students, were a number of representative mining engineers, many of them graduates of the University. Mr. Benjamin Ide Wheeler presided, with a tact that was perfect and a manner that gave a quiet dignity to the whole ceremony.

The President, in opening the exercises, spoke extemporaneously as follows:

"Members and Friends of the University of California: This occasion transcends in significance very materially the opening of a single building, for this occasion connects itself closely with the consistent permanent building plan of the University—a plan for buildings of an established standard. We owe the arrangements for that plan to the generosity and forethought of the same woman to whom we owe the building of the structure itself.

"The architectural plan adopted after the acceptance of Bernard's sketches is being adapted to the practical needs of the University by the University architect, John Galen Howard. The plan is there, and it will abide. This building belongs to the plan. California hall belongs to the plan. The Greek theatre, which we owe to another member of the same generous family, belongs in the same plan. The as yet uncompleted president's house and the central heating station, of which I am very proud, belong in the plan. So there are five buildings practically completed that belong in the permanent plan. Then, again, the foundations are being laid for the Doe library. That will be part of the plan. So will the Boalt law building that is soon to be erected.

"The standard of buildings has been fixed, and coming generations will not dare build shabby buildings on this site. We owe that fact to this building and to Cali-

fornia hall, that have set the standard for the future. They are built of honest material, honestly put together, and they tell the world that we feel nothing is too good for the University of California.

"We are assembled under the auspicious presence of three generations of the family Hearst. Regents, students, and faculty have assembled here to look upon this occasion, knowing it has great significance. For this is the best building of its kind ever reared for the advantage of the sons of men. It is a building to the memory of a plain, honest, good miner, who had a good heart toward his fellow men. He was a man who did much for humanity. His was the riskful search in the hard places of the earth. He took his riches from the hills, and stole from no man, nor lessened thereby any man's store or any man's opportunity."

The next speaker was Mr. John Galen Howard, the architect, who delivered a scholarly address; saying in part:

"First of all let me seize this auspicious moment publicly to acknowledge my heartfelt gratitude, not only from the most personal and intimate point of view, but as a member of the community—the great community at large, and even more of that smaller and more dumb, more secluded community of art, for which I feel the most poignant concern—let me express my gratitude, I say, for the very exceptional opportunity which was presented in the design of the Mining building. The most fortunate conditions were most fortunately combined at the inception of this work. Springing as it did from the wish of its founder to set up a worthy memorial of her husband, which should consist in the carrying out of a great public benefaction, the work began great and noble; in beauty and in breadth the idea of the memorial developed in the heart of its founder until it blossomed in the magnificent plans for the Greater University.

"We have tried to make our building so that its main structure shall be, as far as possible, a mere shell, whose interior portions may be torn out, adjusted, rebuilt, if necessary, without affecting the strength or aspect of the whole, and at a minimum of cost. For instance, the need of innumerable chimneys and ventilating flues for furnaces, hoods, etc., presented itself as a serious difficulty at first, especially as chimneys, connected with such furnaces as are to be installed here, burn out in the course of time and require to be renewed. This difficulty we overcame by building all of the chimneys which are likely to be subjected to such extreme wear and tear entirely independent of the structure proper. Any or all of these chimneys can be taken down to the foundations without in any degree affecting the building or its equipment, excepting as the actual reconstruction of the chimneys themselves obviously involves such changes.

"The dominating idea in the arrangement of the parts of the building is to keep the administrative and more public parts of the building in the front or south portion. Of these the most important, artistically, is the great memorial vestibule-museum, which occupies the centre of the south façade, lighted by the three great arches, under which we sit, and running through three stories to the roof.

"Behind this southern suite of apartments are three wings extending toward the north; the central space, which is the core and heart of the building, being virtually a great top-lighted court, to be devoted to the purposes of the mining laboratory. The east and west wings on the exterior, corresponding to the central court in the interior, are arranged for metallurgical laboratories and for special and research laboratories. Above these are a series of drafting rooms.

"Within, everything is work-a-day, substantial, and

convenient, but totally devoid of ornament, as a building of this character should be. It is a mining building first, last, and all the time, both inside and out. We have sought to secure beauty, not by easy masquerade and putting on of architectural stuff, but by organic composition, working from within out, and letting the heart of the thing speak.

"Useful; beautiful. Our dearest wish has been that this building should be able to brave these times and the times to come with a front modest, yet frank—simple, clean, sterling, permanent—beautiful in its sincere and assured though reticent way, but devoid of anything remotely suggestive of overdoing in the way of ornament or pompous grouping of its parts—its poetic message stripped of verbiage—classic to the core, yet classic of that primitive type which might almost be called archaic, were it not that it is quickened by the breath of modern life."

Then followed Mr. S. B. Christy, dean of the College of Mines; his eloquent speech was much appreciated,

human nature, stronger even than the desires for personal immortality, is the desire that the memory of those we love shall endure in the land of the living. But how seldom is that desire realized!

"The only permanent monument to the dead is service to the living. The greater and more universal that service and the deeper it takes its hold upon our common human needs, the more enduring the monument.

"For the first time a fitting monument has been erected to one of those strong natures that possessed not only the creative imagination to see great possibilities of wealth in what appeared to others mere barren wastes of rock, but also the sturdy faith in Nature that actually moved mountains to realize those imaginings. Such men have created an empire. It is timely and fitting that a monument should be created to one of them.

"It was an adequate deed. Deep rooted in the eternal hills, this memorial to Senator Hearst raises its noble head into the luminous air, and stands in simple dignity, beauty, and strength. Hewn from the solid granite of

The Mining Building, University of California.

being punctuated with applause. Among other forceful things, he said:

"In the history of mining schools this noble building marks a new achievement. Never, until it was undertaken, had the chief department of a mining school been adequately housed. Everywhere in Europe, as well as in America, the fundamental and necessary, but for this purpose, auxiliary departments, have needed so much space for their laboratories and museums that the department of the mining school which deals with the mining and working of ores, the department in which the work of all the others culminates, has had to struggle with them for room to exist and means to develop.

"We are here to commemorate a noble act. This was a generous deed. Who of us, overwhelmed with sorrow, stops to think of others? We all condone and even expect selfishness in those who suffer; and it is only a deeply generous nature that can think of others at such a time.

"Years of anxious waiting, fire and flood, earthquake and tempest, have passed since the idea of this noble memorial was first conceived; but the mind that conceived it has never stopped to count the cost nor to measure the sacrifice.

"It was a wise deed. Among the strongest desires of

our own Sierra Nevada mountains, molded from the plastic clay of our own valleys, and bound together with bonds of steel; designed with consummate skill, and executed by hands that loved their work; it went through the great earthquake absolutely unscathed, as if Nature herself had taken it under her protection."

Mr. Wheeler then introduced Mr. T. A. Rickard. The President said:

"As a representative of the profession of mining engineering, and as a representative of the mining industry at large, I am glad to introduce T. Arthur Rickard, editor of the *MINING AND SCIENTIFIC PRESS*, and I am sure you will be as glad to hear him as I am to give this introduction."

The address delivered by Mr. Rickard, which was cordially received, will be found on another page.

Then followed a pretty incident. Mr. Wheeler walked down the steps, and taking little George Hearst (3½ years old) by the hand, he led him from his mother's side to a position on the steps of the building in full view of the throng. The students broke out into a cheer, that echoed among the groves of eucalyptus that frame the campus, while the sunlight played on the serious face of the child.

Thereupon Mr. William Randolph Hearst was intro-

duced, and made a speech which evoked repeated applause. He said:

"My Friends: My mother has a great happiness, which I and George Randolph share, in erecting this monument to the memory of George Hearst and expressing in this memorial his connection with a great and valuable profession and his interest in the University of California and in the State of California.

When George Hearst first came to California in 1850 the bare hills of Berkeley looked across the bay to the bare hills of San Francisco. The tents of San Francisco huddled at the water's edge. But soon the city grew and covered all the hills.

"A year ago the hills were bare again; bare and black and desolate; and there were those who feared the future and doubted and despaired. But now in one short year the hills are once more covered with the myriad buildings of a mighty city—a proud, defiant city, which no catastrophe can conquer; which no disaster can discourage or destroy!

"It is a pleasant time to dedicate a building which a pioneer of the past offers to the generations which shall succeed him. It is a time which justifies fully and completely the beautiful confidence which the pioneers of California had in the glorious future of this great State.

"The founders of California were a strong and courageous race of men. They reached this country through difficulties and dangers; they wrested their fortunes from the rocks; they gained their knowledge in the hard school of experience.

"They loved the land of their adoption; they pictured its progress, dreamed of its development, and all the time they builded, strong and true, the firm foundations of its greatness and prosperity.

"And all they did, they did for us; and all they gained, they gained to leave us; and institutions such as these are founded to make our paths of learning pleasant places, and to transmit to us and to generations yet to come the hard-earned knowledge that these pioneers acquired.

"It is for us of the present generation, for you of the coming generations, to carry on to full fruition the noble work which the founders of California so well began. In the direction and prosecution of that work this great university will play a leading part; and if this institution dedicated today shall do its share and be of service, my mother will be richly rewarded.

"But, my young friends, it is just as well to realize at the starting that a mining building does not make a mining engineer. Scientific cutting may be needed to develop the full brightness of a diamond, but no amount of cutting will make a pebble shine.

"Success is not hidden in these hills, but lies deep down within your hearts and souls, and with much labor must be dragged from there into the light and assayed in the fire, just as the precious metals must be dug from the earth's depths and smelted in the furnaces and wrought and made to be of value to mankind.

"My young friends, you can and must and will succeed. Success is the destiny of California—the heritage transmitted from your sires!

"My mother rejoices at this opportunity to contribute something that may be of value to you in your careers; and we are proud to stand here today connected in some measure with the achievements in the past of George Hearst, to whom this building is dedicated, and with your achievements in the future, my young friends, to whom this building is presented."

Then the President called upon the audience to conclude the proceedings with the singing of 'America.' And so ended the ceremony of dedicating a building of deep significance to technical education.

California Ore Testing Company.

The lack of ore testing facilities west of Salt Lake City, and the rapid development of the great mining regions of Nevada, have led to the installation in San Francisco of what is probably one of the most complete and elaborate ore-testing equipments in America. The purpose of this plant is to solve problems of ore treatment, particularly with reference to the treatment of gold and silver ores in which cyanidation plays so important a part. Operations will be on a large scale, and ores will be worked preferably in carload lots. But the plant will be in no sense a custom mill. A detailed report will be furnished with each test outlining the proper method of treatment, with recommendations as to the best apparatus to adopt. What has hitherto discredited ore-testing plants is that they have usually been in the hands of apprentices and chemists with little or no practical field experience. Their conclusions are hardly more than a disconnected report of routine experiments, from which the mine-owner obtains no guidance, and little practical information. To guard against slovenly work, the Company has secured the services of Abbot A. Hanks, the well known assayer and chemist, as manager, and F. L. Bosqui, as consulting metallurgical engineer.

The plant was designed and installed by the Coast States Construction Co., in consultation with F. L. Bosqui. It is equipped with a laboratory where small tests can be carried on preliminary to the mill-runs.

The scheme of treatment is as follows: The ore is delivered to a Blake crusher and elevated to a Snyder sampler, the reject being delivered by chutes to the bins, the sample dropping to the sampling-floor, where it is quartered down for assay. There are four storage-bins for ore to be reduced by wet processes, the two smaller bins to take the oversize and undersize from a shaking screen, the former passing to crushing rolls. These small bins, therefore, are set aside for experiments in dry crushing and from them the ore may be trammed direct to the cyanide leaching-vats. From the other bins, the ore may be fed either to rolls, a five-stamp battery, a three-stamp battery, or to a Huntington mill. There are three sets of copper amalgamated plates, from which the pulp is raised by a sand-pump to a Callow screen. Directly under the screen is a double-cone hydraulic sizer, and by means of the screen and sizer, three distinct products are made preparatory to concentration, which, by a very flexible system, can be carried to any one of the three concentrating machines, namely, a 6-ft. Frue vanner, an improved card concentrator, and an A. & E. canvas slime table.

The pulp from the concentrators is again elevated by a pump to a Boss classifier, which separates the pulp into sand and slime. The sand passes to the leaching-vats, the slime to a settling and decanting vat. The slime is treated by cyanide solution in an 8-ft. Hendryx agitator, and passes thence to either the Butters or Hendryx vacuum-filter. An Abbé Jumbo tube-mill of one-ton capacity has been installed for fine grinding. This is charged from the leaching-vats, and the discharge passes to the agitator and thence to the vacuum-filter. Suitable water and solution-vats have been provided, and several individual zinc-boxes for precipitation.

The company has given special attention to the type of apparatus installed, and has endeavored to make the plant sufficiently elastic to meet the widest variations of treatment. As the occasion arises, other machinery will be installed, but the policy of the management is not to adopt any new inventions or processes until a long practical demonstration has proved their value.

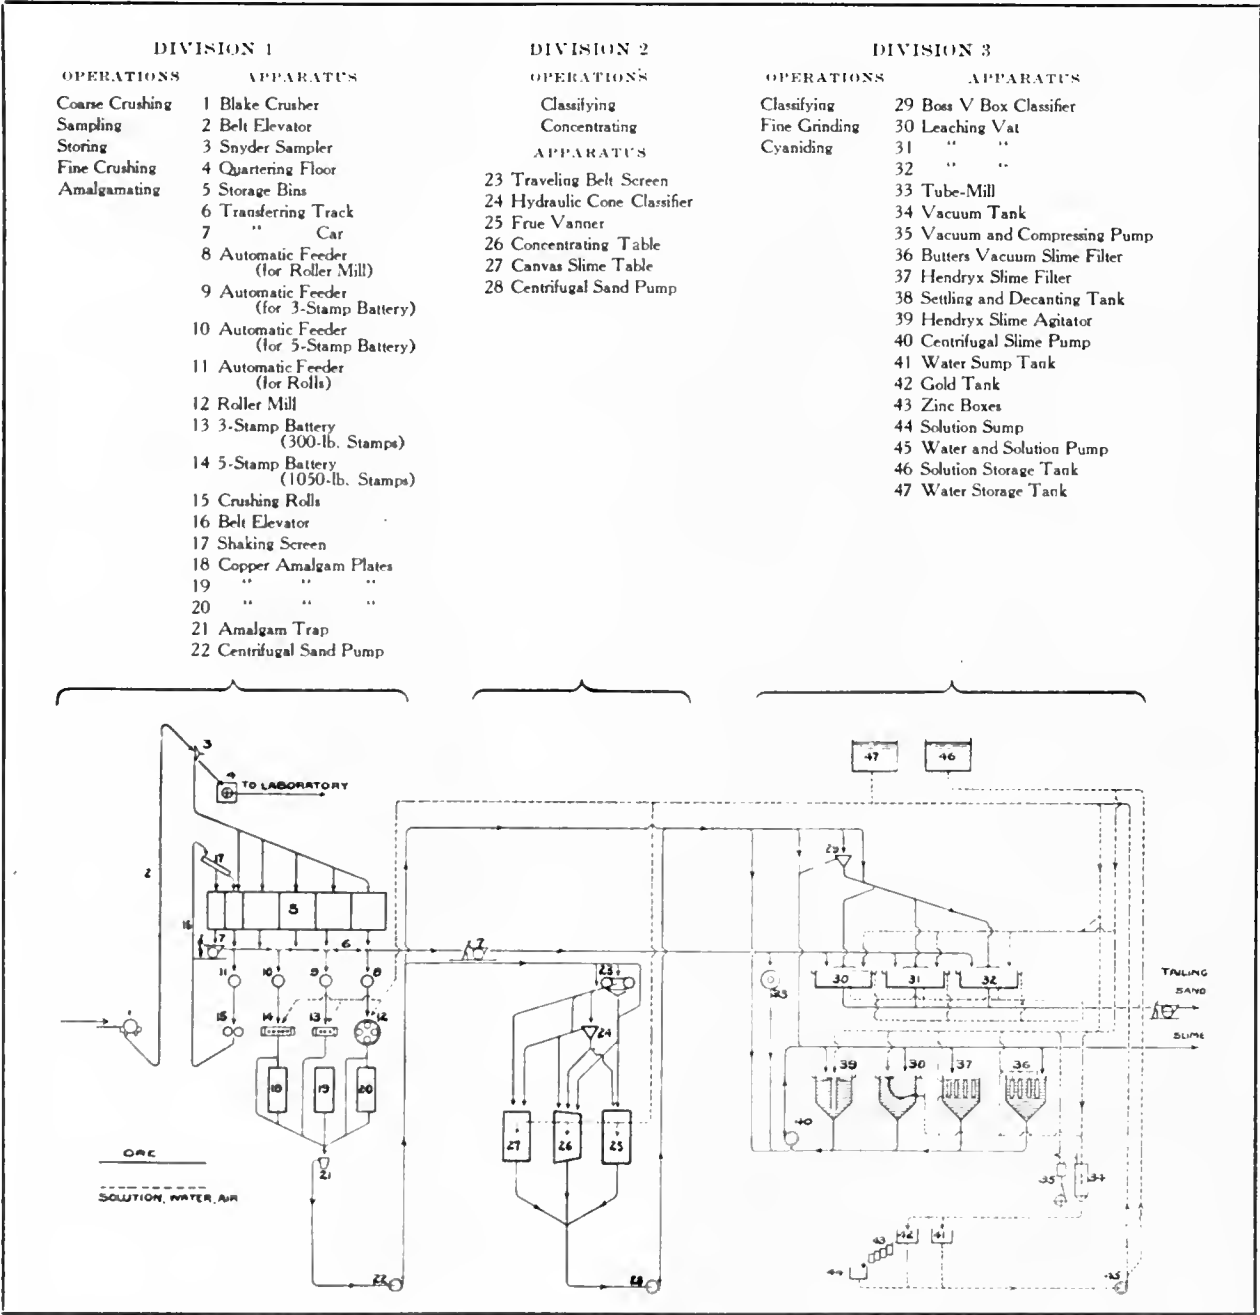

The plant is situated on Bay St., near Jones, in San

Francisco, and the office is at 425 Washington St. All communications should be addressed to the office. A descriptive circular will be furnished on application.

OIL IN BURMA.—The oil mills of the Burma Oil Co. are large and are situated at Poozoondoung, on the river a short distance below Rangoon. This is the third largest oil company in the world, but fears foreign competition, and so far has succeeded in blocking all efforts to secure permission to erect storage tanks at Rangoon. This forces its rival to import all oil in cars instead of in tank

value of \$8,568,900 in 1906, as against 16,542,432 gal., valued at \$2,654,038 in 1902. A high grade of water-white oil is now locally refined and claimed to equal that from America. At present Burma exports little fuel oil, though this is used in the refineries and tank steamers of the Burma Oil Co., and on several of the Irrawaddy Flo-tilla Co. steamers. Consignments of petroleum have been sent to India, but as yet on a very small scale.

NEW CHILEAN RAILWAY.—Work on the railway tunnel through the backbone of the Andes is making excel-

Flow Sheet of Testing Plant.

steamers, which puts the Standard at a disadvantage. At the same time the Burma Oil Co. is enlarging its facilities and improving the quality of its oil, so as to gain the complete monopoly of the Indian trade. It commenced its own transport in tank steamers in 1900 and has raised a fleet of vessels of a capacity of 500,000 gal. each. It has established ocean installations for bulk oil at Rangoon, Chittagong, Calcutta, Madras, Bombay, Marmagao, and Karachi and has besides for the distribution of its oil a network of minor installations all over India. The exports of kerosene oil continue to increase rapidly, amounting to a total of 52,926,107 gal., of a

lent headway, about as much having been accomplished during the past six months as for the previous 18 months. At the present rate it should be completed before the winter season of 1909 sets in, which will be May 1 of that year. The tunnel is at an altitude of 11,500 ft., and is about 2 1/2 miles long. The State railways of Chile are valued at \$61,310,261, of which \$11,681,169 is invested in rolling stock. Nearly all the equipment is of European production. Extensive lines are planned for the near future. The cost of operating these lines for 1906 was \$7,007,379. The expenses exceeded the receipts by \$888,539.

Keeping Account of Supplies.—I.

Written for the MINING AND SCIENTIFIC PRESS
By MATT. W. ALDERSON.

A great many mine managers, while recognizing the obvious advantage such a record would be, are no doubt deterred from keeping an account of supplies used by each individual miner because they imagine it must involve a great amount of work. Not having attempted anything of the kind, they think it must be quite a complicated affair. But the most complicated thing becomes simple when its details are systematized.

A knowledge of cost is considered to be the secret of success in the manufacturing world today, and great pains are often taken to know the exact cost to a fraction of a cent of each piece that goes into the finished product. How few in the mining business ever think to get down to details and know exactly what is being done. "If the mine pays, we are in luck; if it doesn't pay, we're out of luck." But whether a property pays or not would not seem to be a sufficient excuse for lack of approved business methods. Then in mining, as in other fields of effort, there is a better chance of success when things are run on business lines. It is easy to find mines where one man will use twice as much dynamite as another in doing the same work. It is easy to find men who will burn three candles where others will burn but two. It is easy to find persons working properties who have no idea as to which of their men are economical and which extravagant. No attempt is made to find out. In other lines of business it is found necessary to protect the house against those disposed to steal from it, but in the mining business it is assumed that everything is all right. Most miners are honest, but occasionally a man will pocket supplies and walk off with them. A few sticks of dynamite a day will in a month give a man a 50-lb. box full and it is never missed. It is not because every clerk is a thief that the business man must throw safeguards around himself; but because an occasional employee is unable to resist the temptation to do wrong. Why should not the intelligent mine superintendent be up-to-date in his business methods? When the subject of saving on candles and dynamite is broached, many will say, "Oh, that's too small a thing to bother with." But suppose there are 50 men and each of them used two candles a week more than he really should (and there are hundreds of mines where a worse record than this is made), there is an unnecessary loss in that mine of \$100 per year. And if that much loss can be shown on one of the smaller items, is it not reasonable to suppose that there are larger leaks elsewhere? And isn't a hundred dollars worth saving? Isn't it better in the owner's pocket than wasted in carelessness or extravagance? What would be thought of the cabinet-maker who would give to his workmen three boards to make what could be made with less than two, and let the men carry the unused material home? He would be laughed at as exceedingly foolish. And yet that is what we do every day in our mines.

Many managers are no doubt liberal in setting out supplies to their men, because they feel that they must be good to the men, that they must avoid giving the idea that they are stingy. But one is not good to his men who trains them in extravagant ways, and allows them to carry home with them what is really not theirs.

The giving out of the supplies is nearly always left to the judgment of the foreman, generally a man with a good practical knowledge of mining, but without business training. He is apt to do as he has done in other mines with which he is familiar. If it were suggested that he keep a record of supplies used, he would most likely

think that such work should devolve on clerks in the office.

How many candles should a man receive? A standard authority, in speaking of illuminants in mine work, says: "The consumption averages three candles per man per shift." At one mine with which I am familiar, managed on excellent business principles throughout, the men receive three candles one day and two the next. This is the most economical practice I know of. Many mines issue three candles a day to their men and many others let the men help themselves. I turn to my record and I find the following:

		Average per week.	Average per day.
1 man	8 weeks.....	13.75	2.29
1 "	10 "	13.40	2.23
1 "	9 "	12.11	2.02
1 "	8 "	11.12	1.85
1 "	8 "	10.12	1.68

The first three men of which record is given above had to light their way hundreds of feet in going in and out from their work, part of the way in a strong draft, and used their snuffs with which to warm the water of their powder-thawers. The last two used candles in regular work only. More candles are needed in some places than in others. Thus the man working with a machine, where there is a strong draft, will use more candles than one at single-hand work in the end of a level. Where the levels of a mine are lighted by electricity and men need candles for their work only, good men will not use two candles in an eight-hour day. The cheapest candle on the market will burn five hours if held in an upright position and burned where there is no draft. I have timed myself more than once to find that in mucking, where the candle was moved frequently, one would last me $4\frac{1}{2}$ hours. When I was drilling and the candle hung undisturbed most of the time, it would last longer. If I were to use an average of two candles a day under a boss who understood his business, I would expect him to know that something was wrong and needed looking after. The issuing of three candles a day comes down to us from the time when it was sometimes necessary to walk thousands of feet in the light of a candle and then work 10 to 12 hours. Now when entries are lighted and the hours are reduced to eight, we continue the practice.

At many mines the men receive a candle a day more than they use. I know of several mines where the expense for candles can be cut squarely in two. I know one manager, a man of more than local prominence, who would be dumbfounded if shown that he was giving his men two boxes of candles a week more than they used. Yet that is what he is doing, month after month. It's a little waste of \$582 per year, that's all.

At some mines effort has been made to check unnecessary waste by giving the men candles of a special color. But this does not get at the root of the matter. This does not prevent the men when they get a new supply from emptying their candle sticks and putting in fresh candles. As the men do this, they throw away lengths varying from one to three inches. And the longer length is good for two hours. Where a man is of an economical turn, he does not waste, but takes his savings home or gives it to some one with a family who needs more light in the home at night. Every effort to make the prevailing method a success seems to have resulted in failure. It is radically wrong from the start, and cannot be swung into line in an effort to make the issuing of supplies systematical and economical.

In a free-milling ore, the gold occurs in such a form that it is readily and completely recovered by crushing and amalgamation.

Education of Mining Engineers.

By T. A. RICKARD.

*When I was invited to be present on this interesting occasion, it was stated that a few remarks were expected of me as the representative of the public. The public, as you know, is a much-abused entity; it is supposed to be warmhearted but ill informed, and that is why it is possible for so aberrant an individual as myself to speak for it. Assuredly the public takes a keen interest in the mining department of the University of California and rejoices in any further facilities provided for the education of engineers in this School of Mines.

It may be profitable to consider what the public expects, what it gets, and what it may hope to get from the educational advantages offered by the scheme of instruction that is typified by the splendid structure opened on this day. I need not tell you that the public is unreasonable in some of its expectations, for that has been a characteristic of the public from time immemorial, from the day when in Rome it cried for 'bread and circuses' to the day when in San Francisco it expects cheaper water and more theatres. The public is unreasonable, for it supposes that the young men who undergo three or four years of tuition in a School of Mines are necessarily mining engineers, fully equipped to run a smelter, direct the operations of a mine, or pass judgment upon the value of an ore deposit. Occasionally the error of the public is shared by the young graduate himself, who is ready to accept responsibilities as large as his lack of experience. The sequel is lamentable. A career is spoilt; the public grows that scientific men are impractical, and forthwith entrusts the spending of its money to the other fellow—the man called 'practical' because he is ignorant of technical science. The result is again disastrous; for the industry of mining requires more than the rule-of-thumb of the untrained worker and more than the undisciplined theory of the young graduate; it requires that method be joined to experience, that the thought of the lecture room be chastened and illuminated by the realities of life, that is, by getting alongside of facts.

The public expects that the youth sent out from these laboratories and libraries shall be the finished product of a highly specialized education. That is well. To the young man trained here the world is an oyster and his training the instrument for opening the great bivalve that contains the pearl of success. But in the enthusiasm of its belief in the efficacy of a particular curriculum, the public goes too far; it expects the sons here educated to be able to earn big salaries, to discover mines, to guide the uncertain footsteps of finance—all of which is magnificent, but within the gift of no course of instruction as yet devised by man or regents. Such expectations express the flamboyant spirit of an enterprising people and they are eloquent of the respect that the modern world feels for science. Science is a light to make plain the orbits of the stars and to illumine those dark places underground where the miner digs for golden ore; science has done so much to advance the complex method of living we call civilization that mankind, especially that nondescript portion of it called the public, is disposed to ask the impossible. A course in geology will not turn a young man into a divining rod, a few lectures in chemistry will not graduate an alchemist, nor will all the folios in the library teach even the most energetic where to look for the hidden ore. Before science was, common sense was, and experience, and character. These are all needed, and these come slowly; they bud on the campus

of the University but they come to the full flower only in the arena of life.

And what does the public get from a School of Mines such as this one of the University of California? The answer is obvious. It is said of men that by their deeds you shall know them; of Schools of Mines it may be said that by their graduates you shall judge them. If you desire to ascertain what the mining department of the University of California has done for the advancement of a great industry, you must travel, you must go to the waste places of the earth, to the high mountains and the wide deserts, to the tropical South and the frozen North, to the islands of the seven seas, for there you will find the sons of Berkeley, and you will find that they have 'made good.' It has been my privilege to meet the alumni of this School of Mines in many lands, and I can say, without prejudice, for my Alma Mater is an older less progressive lady far from here, that the Berkeley mining graduates have done honor to the University of California. How much of their efficiency is due to the fact that they are the sons of men that explored a continent, how much of it is due to their being the citizens of a commonwealth that gives to each man an equality of opportunity, whether it was due to innate or acquired qualities, it is not for me to say off-hand, but I do know that it is due in large measure to an excellent training and to capable teachers, particularly to professors having the rare ability of Samuel B. Christy and Andrew C. Lawson. If the public expects good men to be graduated from this School of Mines, it ought to be content, for it has obtained them. The records of the profession of mining and metallurgy are liberally sprinkled with the names of Berkeley men that have won an honorable reputation by the exercise of their ability. It is fitting on this occasion to mention the names of some of the past students that have gained distinction in mining, metallurgy, and geology: In South Africa, Gardner F. Williams and his son Alpheus, Harry H. Webb, Wager Bradford, R. H. Robertson, Henry Hay, William W. Mein, L. A. Womble, Paul Selby, the three Hoffmann brothers (George, Carl, and John); in metallurgy, Charles Butters, C. W. Merrill, F. L. Bosqui, P. R. Bradley, E. L. Oliver; in geology, F. L. Ransome, Charles Pakache, George D. Louderback, John A. Reid, S. Tangier Smith, F. C. Calkins, Adolph Knopf, and E. S. Larsen; in general professional work, R. Chester Turner, Ross Hoffmann, Ernst Denicke, Arthur C. Nahl, E. A. Nis, T. D. Murphy; in Ecuador, F. M. Simpson; in Korea, A. E. Drucker; and nearer at home, one of the foremost mining engineers of the world, F. W. Bradley; his associate, Stanley A. Easton; and my own kinsmen, Thomas and Edgar Rickard.

Like the jewels on the breastplate of the high priest, the names of good men give lustre to their University, and they do honor to the School of Mines that honored them. And let me pay a tribute to the greater number of those destined to win no fame, to make no splash, to raise no dust, who in a quiet way are doing their duty in mine and mill the world over. If their education has not been in vain—and I never doubt it—they will be content with the daily task well done, and the routine work faithfully executed; even if their names do not appear in print or in the froth of the daily press, they will not be without honor from those that know them, and the warm heart of their Alma Mater will beat as truly for them as for those that have won a reputation.

And what more may be expected of this School of Mines if it has done so much? Something more remains. This School of Mines is a part of a University, it is expected that the graduates in mining shall have the uni-

*An address delivered at the opening of the new Mining building of the University of California, on August 23, 1907.

versity spirit. That does not mean getting together to give the college yell, that does not mean fraternity pins, nor the solidarity of a trades union, it means much more—a love of knowledge for its own sake, a desire for truth as the only scientific method, a loyalty to principles that is superior to circumstance, and moral courage that is better than that of the football field—in a word, the qualities that make a good citizen, for a good citizen is far more than a successful professional man. Gentlemen, it is the character and style of Joseph Le Conte that I want to see superadded to the technical ability and scientific training of the graduates from this School of Mines. It is twenty-two years since I first came to Berkeley on a visit, then fresh from the classroom of Thomas Henry Huxley, and I took the opportunity to listen to some of the lectures of Le Conte and to have the honor of an introduction to the great geologist. It is fitting on this occasion to refer to the man who first gave fame to the University of California; he was a thorough student and a true philosopher; above all he had those sensibilities that make the gentleman, in thought, manner, speech, and act. He typifies real university culture, not mere diletantism, but the sincerity of science, which offers windows into the infinite, and the generosity of a liberal education, which “widens the intellectual field and adds to the fleeting present those old and new worlds of the past and future.” A School of Mines whose titular chief is a professor of Greek, and a statesman, ought to turn out no narrow specialists, no lop-sided half-educated mental dyspeptics, but men of broad culture, lofty ideals, and wide sympathy. That is what the public may hope to get, and if it does not hold such hopes, it ought to.

But, Sir, in behalf of that portion of the public immediately interested in mining and having a desire to see this School of Mines even more directly useful in the scientific development of industry, I venture to make a practical suggestion. You have a splendid building, but architectural triumphs do not constitute colleges, any more than the house itself makes the home. More is needed. It is true you have a mining department of established reputation, and it existed before this building. You house it now in suitable quarters. These finer quarters indicate a larger sphere of usefulness, but to confirm the highest hopes of the public it is necessary to have an adequate teaching staff. These granite columns are handsome indeed, but they are only an adornment; the School of Mines rests in its professors and students, in the spirit that animates their efforts to train and to be trained in technical science. In the dean of the college and in the professor of geology you have two men that can hold their own anywhere; they are recognized in the mining world as leaders in their subjects and in the teaching of them. That is well known. Nevertheless, in regard to mining and metallurgy, at least, the field of knowledge is so wide and it is widening daily so fast that no one man can keep abreast of it. I say deliberately that no professor of mining or of metallurgy in any school of mines in existence keeps in close touch, or can hope to keep in proper touch, with the development of the arts concerning the practice of which he lectures daily—simply because he cannot be in two places at once. His vacations are occupied with summer schools and with sundry duties that consume even that short period of supposed leisure. His sabbatical year comes at intervals too long to serve the purpose I have in view. What is needed is the endowment of the chairs of mining and metallurgy so that there may be two professors for each chair, one man to lecture as a teacher, the other to study as a scholar in the mine, at the smelter, wherever he can best accumulate the latest knowledge on his subject. Let them take turns—a year

of learning followed by a year of teaching, successively. Thus your lecture room will give no distant echo of the mine and mill, but will be in instant harmony with the latest phase of progress; it will be a place to learn not how things were done ‘once upon a time,’ but a source of instruction telling how they are done now, in the vivid palpitating present. The first School of Mines that adopts some such method will be in accord with the requirements of an industry the wheels of which are never resting but always advancing. Unfortunately it is easier to get money for a building than for a professorship, for the first appeals to the artistic as well as to the altruistic instinct, and the acquisition of chairs, whether domestic or philosophic, must follow the completion of the house as of the college building. California has many men whom her mines have enriched, may we not hope that one or more of them will supplement the beneficence betokened by this edifice and that those others will contribute the money needed to equip this College of Mines with an adequate teaching staff?

However that may be, a great deal has already been done; you have a School of Mines of which the State is proud, and you now have quarters worthy to house it. The public that goes down the mine in skips takes a keen interest in the welfare of this department of the University and, need I say it, appreciates the generosity of the noble woman whose queenly munificence has crowned this campus with an edifice that is at once a memorial to a miner of rare judgment and a token of the part played by the industry of mining in the history of California.

May this building be consecrated to the service of efficient citizenship and to the industrial development of the Pacific Coast, of America, of the world. May this School of Mines have no enemy save the ignorant, and for a friend—the people of California.

THE EXPORTS from Honduras during the last fiscal year included ore worth \$835,597, and bar silver, \$325,286. Exports from Amapala to the United States during the calendar year 1906 amounted to \$1,102,563, of which \$1,005,466 was gold and silver bullion and concentrate. The other exports included cyanide products worth \$13,584. San Juancito is essentially a mining district, and business there is dependent on the operations of a mining company, which during the calendar year 1906 mined gold and silver to the value of \$1,010,000, all of which was exported to the United States. The imports monthly, excepting explosives and candles, amount to some 50 tons of American goods. The works are constantly increasing, and modern methods of ore treatment are being introduced. A new cyanide mill and electric-power plant increased the property value. To facilitate transportation to and from the coast three auto trucks were brought as a trial, and are giving good service over the newly-finished cart road. In addition to wages for the past year, the company expended in the country for produce, salt, etc., \$95,000; besides, its importations from the United States amounted to \$240,000.

SHASTA COUNTY COPPER DEPOSITS.—The study of the copper deposits of Shasta county, Cal., will be continued this season by L. C. Graton, of the U. S. Geological Survey, who will bring the work to completion by mapping the areal geology of the Little Backbone and Iron Mountain districts and studying three large and a few small mines. Mr. Graton will be assisted in this work by B. S. Butler. The future of the Shasta district is most promising. Three smelters are now in active operation, one old one is being overhauled, and a new one is being built. Copper ores from this district are also being smelted in considerable quantity in the vicinity of San Francisco.

The Clean-Up, Melting, and Refining of Gold Bullion.

By GERARD W. WILLIAMS.

*The absence or presence of objectionable precipitate in the extractor-boxes is a factor that involves careful consideration. Generally speaking, it is advisable to screen the fine zinc, putting back in the boxes such zinc as does not pass through the screen used. In this connection a description of the trommel employed in the Simmer & Jack mill may be of interest. It consists of a cylinder of wire-screening with thin sheet-iron ends. A door is provided in the side of the cylinder; the latter is of such size that it revolves easily in one of the extractor-box compartments or in the washing-box used for the purpose. The gold-coated zinc is placed in the trommel, which is revolved by a handle fitted to the long axis. The trommel revolves half in and half out of the water, and in a few minutes the zinc is thoroughly washed. The washing is more rapid and more complete than where the zinc is hand-scrubbed through a sieve. It is, perhaps, permissible to emphasize here the need of running water through the boxes for at least an hour prior to the clean-up. Not only is cyanide saved, but the danger of hydrocyanic acid poisoning in the subsequent acid treatment is eliminated. In mills where the zinc-boxes become charged with 'white precipitate' (essentially a mixture of hydrated zinc oxide and basic zinc ferrocyanide, with a small amount of calcium and magnesium salts), it is advisable to clean-up at least twice a month. The washing of the zinc promotes better precipitation.

On one mine on the Rand with which I was connected, the solutions leaving the boxes averaged, for all solutions, less than 0.035 dwt. per ton; a result due in no small measure to the care with which the fouled zinc was trommeled twice a month. The cyanide strength of the solutions on this mine averaged for strong solutions 0.08%, for medium 0.05, for weak 0.03, and for slime-plant solutions 0.025% KCN. The gold slime and the fine zinc are treated in three ways on the Rand, namely,

1. Treatment with sulphuric acid.
2. Treatment with sodium bisulphate.
3. The Tavernier process.

Calcination of the washed slime and melting with an oxidizing flux.

The bisulphate of sodium is obtained from the Modderfontein dynamite factory, where it is formed as a by-product. In addition to being much cheaper than commercial oil of vitriol, it is absolutely free from arsenic. All danger of poisoning from arsine is thus avoided. In this connection it may be stated that it is probable that most of the cases of 'gassing' during clean-up are not due to hydrocyanic acid gas, but to arseniureted hydrogen. This second method requires the use of larger vats, as the acid can only be used when dilute. This is no disadvantage in the design of a new plant, the extra cost being small. The mines controlled by the Consolidated Goldfields are all fitted with clean-up plants designed for the use of sodium bisulphate instead of sulphuric acid. The vats are lead-lined, covered, and provided with two flues, and a centrally situated power-driven stirring gear. When sulphuric acid is used, the procedure is similar to that pursued in this State. When all action is over the acid liquid is allowed to settle, and the clear supernatant liquid decanted. In cases where any difficulty is experienced in obtaining clear settlement, the addition of two pounds of painter's size dissolved in a gallon of water will effect a speedy settle-

ment. The slime is then treated with two or three washes of hot water, and after the final decantation is filter-pressed. The practice of placing a sheet of cheap filter-paper over each cloth is an admirable one; it prevents the valuable slime from penetrating into the substance of the cloth. The pressed slime is given a final hot-water wash. The use of hot water in this connection unquestionably facilitates the removal of the cakes of gold slime.

Even after long standing and careful filtration, it will be found that the acid solutions and washes carry appreciable quantities of gold. This is due to the solvent action of HCN in the presence of sulphuric acid, and is particularly the case where an excess of acid remains in the vats after all zinc is dissolved. For assaying solutions the following method was found to yield exact results: To one litre of the solution add 10 c.c. of 1.1 sulphuric acid, and 5 grams of zinc dust. Stir well, and when the zinc is almost all dissolved, add 10 c.c. of 5% potassium ferrocyanide. The resultant reddish precipitate settles rapidly and is easily thrown onto a filter. It is incinerated in a small crucible, fluxed with litharge, sand, and borax. Sufficient carbon is added to give a button of the required size.

The principle involved in this method is now adopted in mills employing the bisulphate process. The spent solutions are run into a large vat, and zinc fume (2.5 lb. to 50 tons of solution) stirred in. After settlement the solutions are run to waste, the assay-value of these discharged solutions being less than 0.1 dwt. per ton.

Filter-pressed slime varies in composition, but the following analyses of the slime before and after calcination may be taken as fairly typical of Rand practice. The analyses quoted are the mean of several determinations of slimes from mines wide apart.

	Before roasting.	After roasting.
	‰	‰
Gold.....	35.8	37.0
Silver.....	3.7	3.8
Zinc.....	2.4
Zinc oxide.....	6.0	27.5
Lead.....	19.1
Lead oxide.....	20.0*
Copper.....	2.2
Copper oxide.....	2.2
Iron oxide.....	1.0	2.5†
Nickel.....	0.5
Nickel oxide.....	0.5
Ferrocyanide [K ₄ Fe(CN) ₆].....	2.9‡
Lime, magnesia.....	Trace.	Trace.
Sulphuric acid (SO ₃).....	6.0‡	8.0
Silica (sand).....	12.5	14.0
Total.....	92.1	95.5

*Lead acetate was used for dipping the zinc.

†The ferrocyanides yield iron oxides (and carbides) on roasting.

‡Some sulphur is present as lead sulphide, not separately estimated.

Two factors are liable to extreme variation, zinc and silica. The presence of the first-named, assuming the slime to be well acid-treated, is due to the presence of the white precipitate. Ferrocyanides of the alkalis are decomposed by sulphuric acid with formation of CO or HCN according to dilution and temperature, but the basic ferrocyanide of zinc which at times forms a considerable portion of the white precipitate is totally unaffected by acids. The amorphous hydrated zinc oxide which forms the basis of the precipitate is practically insoluble in acid. The presence of sand may be due either to sand from imperfect filtration or to dust. The extractor-boxes are not covered.

Copper, nickel, and mercury, if present in the ore, are usually deposited on the zinc, and as these metals are not soluble in sulphuric acid under the condition obtaining, they pass onto the precipitate unchanged. In certain cases soluble sulphides formed from the ore are converted into lead sulphide in the boxes. This may be almost entirely prevented by the use of lead acetate in the sand-vats.

The gold slime is calcined at low redness for some hours, pulverized when cold, fluxed, and melted in clay-lined Salamander crucibles heated in large reverberatory furnaces. Until 1898 it was customary to melt the slime with borax, the resultant bullion being worth about £3 per ounce. In June of that year the present process was introduced. Manganese dioxide and nitre are used to effect oxidation of the base metals, the process taking place in clay-lined graphite crucibles. The following flux would give a good melt with the calcined precipitate: Gold slime, 100 parts; fused borax, 30 parts; soda, 5; sand, 20; manganese dioxide (commercial), 20; nitre, 7; fluorspar, 5. Silicate of soda is sometimes used instead of soda. The ideal flux probably corresponds to a borosilicate, but owing to the cost of borax it is advisable to form silicates with a larger percentage of metallic sub-oxides than shown in the formula.

The fusibility of zinky slime is much increased by the presence of fluorspar. Zinc fluor-silicate appears to be more fluid than zinc borosilicate. The partial substitution of boric acid (B_2O_3) for borax has undoubted advantages when the slimes contain much base metal other than zinc and lead. The replacement of half of the manganese dioxide by the (chemical) equivalent in ferric-oxide tends to increase the fluidity of the slag. The resultant bullion would contain about 975 to 985 parts of gold and silver; care must be taken to avoid excess of manganese, for, in addition to rendering the slag pasty, it has the property of dissolving both gold and silver. On the larger South African mines these slags are run down in a pan-furnace; the residual slags average, on a well-run plant, about 4 dwt. per ton.

It is a good plan to make up a few trial fusions in J pots and to select the flux that gives the best results. This does not take long, but it saves a lot of annoyance and loss of time when, as sometimes happens, the fluxes do not work well.

The Taverner process, introduced on the Rand in 1903, consists essentially in the smelting of the dried and briquetted slime and fine zinc with litharge on the hearth of a pan-furnace. The slag used is generally composed of old assay slag saved for that purpose. The lead bullion obtained is cupelled. The resultant bullion is high-grade. In some cases the slime and zinc are acid-treated before putting in the furnace.

Recent work has shown that the loss by dusting is insignificant, and not more than the loss which inevitably occurs when calcined precipitates are handled. For the treatment of large quantities of very low-grade slime it may have advantages, but with normal slime containing from 35% bullion it appears to possess no points of superiority over the processes described.

The economic limit to which it is advisable to continue refining is in some degree a factor dependent on the country where the gold is sold. Most refining processes involve a loss in the silver contents, and this becomes an important consideration when deciding between realization in Perth and London. At London, melting charges are based on the ounce bullion, so that, all things being equal, it is advisable to reduce the gross weight of the bullion as far as possible. Deductions are also made for gold bullion containing less than 800 mills gold. Another indirect advantage of refining lies in the fact that greater uniformity of assay is obtainable.

Speaking generally, it may be stated, as an axiom, that as much refining as possible should be effected in the first melt. This object is attained by the three standard methods described as representing Rand practice and for pouring into bars it is customary simply to melt the bullion under borax, a little nitre being occasionally

added during fusion. But there are, especially in the Westralian back country, many mines where the bullion does not average more than 500 or 600 fine, and in this case it is necessary to adopt some method of refining. But in this connection the fact is again worthy of emphasis, that if acid-treated slime is well roasted and then fluxed with an oxidizing flux, little difficulty will be experienced in obtaining bullion 900 fine (gold and silver) in the first melt, and this where the conditions do not permit of that thorough washing of the acid-treated precipitate which is so essential for really good work.

For general mine work, nitre is the best refining agent. The bullion is melted in a clay-lined pot and a thin stream of finely-powdered nitre is run slowly to the centre of the molten metal. Then an equal weight of borax to slag the oxides. The process is continued until the slag, which is skimmed from time to time, is light green in color. The slag is partially soluble in water, and any contained prills are readily separated by crushing and washing. The slag may be advantageously used as an addition to the flux in the next clean-up.

It has been shown that copper acts as a carrier of the oxygen from the nitre to the other metals, and further that base bullion may be simply and economically refined by granulation and fusion of the granules and potassium permanganate and borax. It has also been demonstrated that a stream of compressed air passed through molten bullion will remove all base metals without any appreciable loss of gold except the small temporary loss of small prills in the covering slag.

In experiments made in South Africa good results were obtained from the smelting of bullion rendered specially base for the purpose of experiment. The application of the process is extremely simple. The bullion is melted in a lined crucible and a slow stream of compressed air is passed into the molten metal by means of a clay pipe. By the inclusion of a glass wash-bottle in the air circuit, the progress of the air may be watched and accurately regulated. The metallic oxides are fluxed with sand and borax. The process certainly requires time, but the complete immunity from loss, actual or potential, is a great point in its favor. The cost, where compressed air is available, is small. The final bullion is not only extremely fine, but is also quite tough.

The following details of the second bi-monthly clean-up at the Ida mill, in April, 1907, illustrate certain points in the foregoing notes. Fine zinc and slime were acid-treated and thoroughly calcined on an iron tray over a wood fire. Flux:

Gold slime.....	100 parts
Soda	10 "
Fused borax	35 "
Sand	15 "
Manganese dioxide	20 "
Nitre.....	5 "

In another melt the nitre was eliminated as the roast was exceptionally good, and five parts of borax substituted.

The bullion represented 16.5% of the total weight of gold slime. It was re-melted in another smaller clay-lined crucible, and, when molten, 50 grams of an equal mixture of sand, borax, and nitre were added. The slag was skimmed and the bullion washed with a little borax prior to pouring. The bullion assayed 948.5 fine gold, 31.5 silver. The slag from the melt was fluid, dull red in color, with conchoidal fracture on cooling. Before amalgamation it assayed 1.85 oz. gold and 4.0 oz. silver per ton. Copper is the chief impurity, but large quantities of white precipitate are formed in the weak solution extractor-box, thus materially increasing the percentage of zinc in the slime.

This gold slime, if melted down with borax in a graphite crucible, yields a bullion about 600 fine, together with a certain quantity of highly auriferous matte. The following method was utilized for the purpose of treating a small quantity of such matte: The finely-crushed sulphide was mixed with 50% (by weight) of iron filings and melted in an old graphite crucible.

Fig. 1.

Fig. 2.

When melted, more iron was stirred in until it no longer dissolved. The mass was kept at the highest temperature of the furnace for an hour and then allowed to cool. When cool, the pot was broken and a coppery bullion obtained. The iron displaced the copper, forming ferrous sulphide, and set free the bulk of the gold.

SCREENS with flaring holes with the narrow part up do not blind as quickly as those with cylindrical holes. Thus an old trommel screen makes a splendid screen for a fine jig, and one which many millmen prefer to a wire screen.

The Fairchild Vacuum-Filter.

The accompanying illustration shows the details of a revoluble vacuum-filter designed by O. H. Fairchild, of Denver, for the removal of the liquid from slime during treatment by the cyanide process.

The construction and operation of this machine is briefly described as follows: Suspended in a semicircular vat is a circular filter of 10 ft. diam., composed of 14 sections or groups of filters. Each section is composed of 10 filters radially attached to the inner periphery of the filter-wheel with suitable connections through the hollow spokes and hubs with a vacuum-pump on one side and a supply of compressed air on the other. The individual filter is two feet square and there are 10 filters to each of the 14 sections, which gives a total filtering surface of 1,120 square feet.

To operate this vacuum-filter, the vat is filled with thickened pulp to a point six inches above the hub. The filter is slowly rotated and as each section is immersed in the pulp the valve connecting that particular section with the pump is opened and vacuum-connections are maintained until the section emerges from the pulp at the opposite end of the vat and reaches a point directly over the hoppers that project through the sides of the vat. At the latter point the vacuum-valve is closed and the valve controlling the passageway to the compressed fluid or liquid under pressure is opened to discharge the cake of slime.

Fig. 3.

Fig. 4.

Fig. 5.

These valves are actuated by engaging their bell-crank arms with a set of pins at certain fixed points. A three-way valve placed in the compressed fluid conduit operates to admit a solution under pressure and compressed air alternately.

This construction enables the process of filtering to proceed automatically and continuously and permits the discharge of a relatively thin cake of slime, features that will be readily appreciated by cyanide operators. The floor space required for each machine amounts to approximately 135 sq. ft. The filter is manufactured by McFarland & Co., at Denver.

The McDougall Roasting Furnace.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

These furnaces have been largely used in the inter-mountain States and mainly on ores containing 27 to 38 % sulphur. They are roasted by the heat developed from the burning of their contained sulphur, the lower percentage mentioned being the minimum that can be roasted without the aid of a supplementary fire to keep up the heat. These ores can be roasted down to 5 to 8 % sulphur, and it has been found that the roast, under favorable circumstances and for days together, can be

capacity of the reverberatory furnace in which the ore is roasted, while if imperfectly mixed the charge is slower in melting down.

With a battery of four 16-ft. McDougall roasters, each having six hearths of a combined area of 870 sq. ft., a test made upon copper-bearing sulphide concentrate during a continuous run of 10 days, gave an average of 36 tons in 24 hours. A maximum tonnage of 47 tons has been attained by a furnace of this size under favorable circumstances. This corresponds to a performance of 65 tons daily made by an 18-ft. furnace having a hearth of 1,200 sq. ft. That is we have

870 sq. ft. : 1,200 sq. ft. :: 47 tons : 65 tons.

Fig. 1. Elevation of McDougall Roasting Plant.

carried to 2.5 %. Butte ores are roasted to 7 %, and when smelted in a reverberatory furnace they gave a 40 % copper matte, a grade which, under present practice, can be easily converted; hence it has not been sought to make a lower roast than this figure. The time taken to pass the ore through the furnace is 2½ to 3 hours and, in fact, there are 25 to 30 tons in the furnace at any one time including what is in the hoppers. The capacity of the furnace varies with the nature of the ore, its sulphur contents, its moisture, and the fineness to which it has been crushed. Pyrite-bearing ore of the percentage above cited is fine enough if crushed to pass a ½-in. screen, since by decrepitation it breaks up enough to come thoroughly in contact with the air. When crushed to this size and bedded with silicious ore and limestone, the intimate mixture of these latter ingredients assists in increasing the

In the larger furnace (18 ft.) this performance has been attained without difficulty. The water needed to cool the hollow shaft and rabble-arms is 60 gal. per min. delivered at an initial temperature of 70° F., the overflow varying from 103 to 115° F. The repairs on these furnaces are small, the iron parts to be renewed being the plows and rakes, this item amounting to 0.25 to 0.5 lb. cast iron per ton of ore treated. The hearths have to be renewed sometimes, especially the 'cutting hearths,' which are particularly subject to wear and tear arising from removing lumps of partially fused ore. To save the hearth from damage when barring off these incrustations, cast-iron plates cast in Z-form are put in. These constitute the door-sill; they go down through the drop opening and rest on the hearth below; they need no bolts to hold them in place.

When 16 of these roasting furnaces have been driven from a single motor, approximately 25 hp. is needed, or $1\frac{1}{2}$ hp. per furnace.

Fig. 1 is an elevation of a plant where the ore is supplied in a regulated stream to the foot or boot of a vertical elevator, which in turn spouts it upon a troughed conveyor-belt. A movable tripper delivers it to any desired feed-hopper until the latter is full. When the tripper is not filling these feed-hoppers, it may be filling the ore-storage bins. A single attendant can draw from these bins into a car set at the ground level and this is then dumped into the hopper of the shaking-feed. When desired, the tripper can be arranged to deliver coal to a bin in those cases where a supplementary fire is needed. It should be noted that the outlet flue, carrying the hot

peripheries of the hearth in its downward progress. The ore, showering down through the openings, is brought effectively in contact with the upward passing air, but at the same time much flue-dust is formed. Opposite the drop-holes doors *E E* are provided, by which the accretions, which form so much upon the second and third hearths, may be conveniently removed. The ore upon the lower hearth is finally discharged through the base plates by two openings near the periphery, each of 2 ft. by 8 in. area, and enters the double hopper *F F*, 6 by 10 ft. in plan. The shell is lined with fire-brick headers, leaving an effective interior diameter of 16 ft. 6 in. The furnace is 19 ft. high, and its base plate is 10 ft. above the ground floor. The space between hearths is 2 ft. 4 in. The central cast iron hollow shaft *S S* is driven by bevel

Fig. 2.

escaping gases from the main flue, should be lined with tile, or made of brick. The bottom of the main flue consists of a series of pyramidal hoppers, but these are not attacked by the acid escaping gases, since they are continuously covered with flue-dust.

Fig. 2 represents the latest design shown as a half-sectional, half-outside elevation of a six-hearth 18-ft. McDougall roasting furnace No. 1, as made by the Allis-Chalmers Co. The supply of ore is kept in the hopper *B*, 5 by 7 ft. in plan. This is fed automatically by a reciprocating feed-shoe, the movement of which may be readily modified to suit the feed required. The ore enters quietly at the outer edge of the hearth, thus avoiding the formation of flue-dust. It is spread by the rabblers and is plowed by them toward the central opening of this hearth. Here it falls to the second hearth and is swept gradually outward by the second set of rabble arms *D*. At the periphery it falls through six equally spaced drop openings, each of 3 ft. by 8 in. area. Then it is moved toward the centre, and so, alternately, to the centres and

Fig. 3.

gears *M N*, actuated by spur-wheel and pinion on the driving shaft, which also carries the pulley *O*. The rabble arms *D D* are bolted to the central shaft, the joint being made with corrugated copper gaskets covered on both sides with red lead. The water-supply pipe enters the top of the hollow shaft and passes down the interior to a point near the bottom, with branches at each rabble-arm. These branches run through the rabble-arm nearly its full length, and are open at the end. Thus a circulation of water is insured outward to the end of these pipes, and returning by the hollow rabble-arms to the shaft and then rising to the overflow pipe at the top, where it is received into a launder which encircles the shaft.

Fig. 3 is a view, partly in section, of a McDougall roasting furnace, having two fire-boxes with grates, ash-pit and fire-door fronts, one of which is shown. These deliver the products of combustion to a common or single combustion chamber immediately below the lower hearth. The brick lining is 23½ in. thick and in it

are flues 10 by 16 in. area, proceeding from the combustion chamber, and delivering the heat to the second, fourth, and sixth hearths, numbering from the top three flues to each hearth. One of these flues is shown in the section delivering the gases to the fourth hearth. The shaft of this furnace is driven from above. The arrangement and construction of the rabble-arms clearly appear in the sectional view. The furnaces, being set upon the ground, the roasted ore is removed by a single chute to a tram-car set upon a sunken track. The exit flue or pipe is double, joining then into a single uptake. The usual method, however, is to have one or two uptakes leading to a horizontal main flue, or else, as in Fig. 1, to put in a down-take, which leads to a flue at, or near, the ground level. At about the level of the fire-doors will be noticed rods projecting from the side of the furnace. They indicate the position of dampers at the foot of each of the flues above referred to. They are, however, wrongly represented, since these are iron plate dampers sliding through slits in the shell, and they regulate the heat to any hearth as may be desired. As regards cost of roasting, this varies with the locality, since the price of labor is the principal factor. At the Highland Boy smelter near Salt Lake City, in 1892, the cost was 34c. per ton. This included direct charges for repairs, power, supplies, tramming ore, and calcines, and a proportionate share of all indirect and general expense. The eight furnaces take two furnace-men and two helpers per shift.

LIME IN CEMENT.—The amount of lime a cement will safely carry is dependent on the relative amounts of silica and alumina present and also on the care with which a cement is made. Practically all American cements fall between two limits, and the ratio of the bases lime and magnesia to the acids silica, iron, and alumina should not exceed 2.1 to 1 nor be less than 1.9 to 1. To make a sound cement having the first ratio the raw materials must be well mixed and very finely ground. Such a cement will be much stronger, however, than one having the lower ratio. A hypothesis has been advanced that the lime in portland cement clinker exists in three forms: In combination with silica, alumina, iron, etc., to form a magma of orthosilicates, $2\text{CaO} \cdot \text{SiO}_2$, ortho-aluminates, $2\text{CaO} \cdot \text{Al}_2\text{O}_3$, etc.; as the oxide itself in solid solution in this magma of silicates, aluminates, etc.; and as undissolved oxide, that is, lime merely disseminated through the magma, forming with the latter simply a mechanical mixture. If this is assumed, then it readily follows that it is the lime in the second condition which causes the hardening of cement mortars and the lime in the third form which promotes unsoundness. It is barely possible that in some cases with this third form of lime, the lime was at one time also in solution in the magma and crystallized out on cooling. Lime found under such conditions would probably be very slowly attacked by water and hence might easily not slake until after the mortar had hardened, thus causing expansion of the latter with consequent disintegration, distortion, and cracking.

MINERAL DEPOSITS OF ORISSA.—The iron ore deposits in the Bengal province of Orissa have been reported as being practically inexhaustible in quantity, and of excellent quality. A party of Englishmen visited the Gurumaishani deposits last year, they were satisfied with the quantity and quality of the deposits, and steps have been taken to organize a company to work the iron, gold, and other minerals which were reported as being found. Indian capitalists are taking a joint interest with London capitalists in the proposed development of the Mourbhunj deposits.

The Prospector.

Enquiries sent to this department are answered free of charge, is submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The rock marked Comer is a Basalt.

A piece of Kaolinite was sent from Big Oak Flat, Cal., by L. F.

The mineral Scheelite was sent from Randsburg by A. C. W.

The red red pebble marked C. A. B., Eagle, Alaska, is Hematite.

An impure clayey Limonite was sent by J. R. of Mercur, Utah.

The specimens sent from Iron Springs, Idaho, by J. D. T., are Jasper and Diorite.

The specimen marked A. B. C., Battle Mountain, Nev., is Pyrrhotite in quartz and calcite.

The eleven rock specimens from H. G. G. of Wonder, Nev., and numbered from 18 to 19 inclusive are all Dacites.

The specimen sent from Tokio, Japan, by R. K., appears to be a crushed and greatly altered and silicified effusive—perhaps an Andesite. A closer determination is impossible.

The rock specimens sent from Nogales, Ariz., by E. E. N., are: No. 1, Quartz Porphyry; No. 2, Quartz Porphyry; No. 3, Quartz Porphyry; No. 4, altered Andesite; No. 5, Rhyolite; No. 6, Andesite; No. 7, Diorite; No. 8, Rhyolite; No. 9, Quartz Porphyry; No. 10, Quartz Porphyry; No. 11, Quartz Diorite.

J. C., of Mazapil, Zacatecas, Mexico, sends: No. 1, Tetrahedrite; No. 2, Tetrahedrite, Chalcocite, and Chalcopyrite; No. 3, Tetrahedrite, Chalcocite, Pyrite, and Chalcopyrite; No. 4, Calcite carrying considerable iron, etc.; No. 5, Bornite in Calcite and Andradite; No. 6, Calcite, Garnet, Limonite, and Thuringite with some copper stain.

A SIMPLE DEVICE.—Following is a description of a handy device for removing pump rods, pipe, etc., that have been broken off in a drill-hole: Any blacksmith or mechanic can make this tool, using the size iron to correspond to the size of the hole, and for the iron or pipe to be removed. For instance, for 2-in. holes a piece of iron or steel $\frac{1}{2}$ by 1 in. is good size; about three feet long, pointed at one end with a short piece of round iron welded on opposite end, of suitable size to be threaded to fit a standard one-inch pipe coupling. Rings or clevises can be made of $\frac{3}{8}$ or $\frac{1}{4}$ -in. steel or iron, leaving enough room for the piece to slip through them, whence rings stand at right angles to the spear. The rings can be made to take a firmer grip on the piece by filing them to a sharp edge on the inside, so they will cut into the rod or pipe to be removed. The tool is attached to ordinary gas-pipe, enough lengths screwed together as it is lowered into the well to reach the piece to be removed. By manipulating it properly it can be worked over the rod, and as soon as a pull is exerted the rings drop down and take a good grip. If gas-pipe is not available, a ring can be forged in the top and a rope attached to it, but do not use a rope unless you are sure the piece in the well is not tight, as you would be liable to tear the rope. For larger size wells use iron and pipe to correspond.—*The Drill Hole.*

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

GYRATORY CRUSHER.—No. 863,284; Herbert I. Keen, Chicago, Ill., assignor to Allis-Chalmers Company, Chicago, Ill., a Corporation of New Jersey.

In a gyratory crusher, a shaft, a spider for the upper end of the shaft, a plate covering the spider hub, a jack screw threaded through the plate for forcing down the shaft, and a dust cap for turning the screw and shedding debris away from the same.

MEANS FOR USE IN SEPARATING THE MORE SOLUBLE CONSTITUENTS OF A MATERIAL FROM THE LESS SOLUBLE CONSTITUENTS THEREOF.—No. 863,168; Thomas Griswold, Jr., Midland, Mich., assignor to the Ontario Nickel Company, Limited, Worthington, Ontario, Canada, a Corporation.

In means for use in separating the more soluble constituents of a material from the less soluble constituents thereof, the combination of a series of settling chambers and mixing chambers; means arranged to convey unlike constituents from a plurality of said settling chambers, respectively, to said mixing chambers; and means for circulating all said constituents through said mixing chambers in the same direction.

ROASTING-FURNACE.—No. 863,187; George E. Kirk, Toledo, Ohio, assignor to Allis-Chalmers Company, Milwaukee, Wis., a Corporation of New Jersey.

The combination with a shaft, of a supporting member supported by and extended from said shaft, a hollow arm inclosing said supporting member, and a heat insulating packing interposed between the interior surface of said arm and said member.

PROCESS OF REDUCING COMPOUNDS AND PRODUCING LOW-CARBON FERRO ALLOYS.—No. 862,996; Edgar F. Price, Niagara Falls, New York, New York.

The process of reducing refractory compounds, which consists in percolating a molten reducing agent essentially comprising a highly-oxidizable element through a granular body of the compound.

TUBE OR PEBBLE MILL.—No. 863,483; Richard F. Abbe, New York, New York.

In a pebble mill, the combination of a plurality of receptacles secured together about an axis of rotation and each provided with an entrance opening and an exit opening, means for rotating said receptacles about said axis, a gudgeon at each end of said receptacles and rotatable therewith, conduits leading from one gudgeon to the entrance openings of the receptacles, conduits leading from the exit openings of the receptacles to the other gudgeon and spiral ridges secured in the interior of each gudgeon.

PROCESS FOR BURNING LIME OR OTHER SUBSTANCES.—No. 862,657; James Reaney Jr., Sherwood, Maryland.

The process of burning lime rock or other material, consisting in agitating the material in the presence of a burning heat and during the agitation separating by gravity the heavier unburned particles which settle to the bottom from the lighter burned particles which rise to the surface of the mass and removing the lighter separated particles from the surface.

Automatic Water Gauge.

The objections to many automatic gages are that the automatic devices go to their seats on the sudden opening or closing of blow-off or they become corroded, stick fast, and do not operate at the critical moment. An examination of the Success gauge will convince any engineer that these two objections are entirely overcome.

E is a double-seated valve to close both the gauge and the blow-off. It will be seen, therefore, that every time the lower handle is turned to blow-off the gauge the automatic device or ball *D* is moved by the stem on which it rests. In addition to this the stem follows the course of the arrows *B* to the outlet *G*, creating a downward pressure on the ball *D* and rolling it about in the chamber in which it is located. This great agitation of this ball from three to six times a day prevents it from ever becoming limed up and stuck fast. When the glass breaks everything is reversed; the steam rushes upward to the break, creating a strong vacuum at the lower end of the glass, when ball *D* is instantaneously raised to the location marked *C*, when flow of steam ceases. The upper ball is forced to its seat by pressure from boiler. The double seats of valve *E* can be ground by simply loosening the stuffing nut on handle.

The Penberthy Injector Co., of Detroit, Mich., is the manufacturer.

Smooth-On.

This chemical iron compound was made in 1893 by Vreeland Tompkins, a chemical student and graduate of Rutgers College, the object being to make a chemical iron, that could be easily applied to cracks and holes in iron to make permanent repairs. A compound to make such repairs must metalize practically as hard as iron. It must expand while metalizing, so as to completely fill any opening into which it is introduced and also force itself into the grain of the iron. When metalized, it must expand and contract the same as iron. After two years this was accomplished and a chemical compound made and named Smooth-On, which forms the base or starting point for the different Smooth-On iron cements. These were first prepared only in powder form and used, by mixing with a certain percentage of water, to the consistence of stiff putty and immediately applied to cold metal, as it metalizes rapidly. While very useful where small amounts of cement were required, this cement necessitated a hurrying of the work, when handling large quantities to get through before it got too stiff or hard to work. By further experiments a solvent was found which would evaporate upon the application of heat; this enabled Smooth-On to be prepared and kept in paste or fluid form, until wanted for use. The fluid preparation of Smooth-On greatly enlarged its use, as this cement may be applied to hot or cold metal.

Commercial Paragraphs.

A DECIDED NOVELTY in the electrical signal system has been installed at the Mohawk mine, in the copper region of Michigan. The installation is known as the Richmond Mine Signal System, manufactured by the RICHMOND Co., of Oshkosh, Wisconsin. The Ahmeek No. 2 shaft, another

copper mine, is also putting in a complete Richmond system.

CHARLES T. HUTCHINSON, for many years associated with the Union Iron Works of San Francisco, and of late years manager of the mining machinery department, recently severed his connection with that concern, to accept a similar position with the JOSHUA HENDY IRON WORKS, of San Francisco.

Books Received.

'Public Roads; Their Importance and Maintenance,' by E. R. Buckley. This useful volume of 120 pages is issued by the Missouri Bureau of Geology and Mines, and written by a geologist of established reputation. The book is well illustrated and contains a good deal of practical information on a subject of fundamental importance.

'The Mineral Industry.' Vol. XV. Edited by W. R. Ingalls. Issued by the Hill Publishing Co., New York. This volume gives the statistics for 1906. It is published earlier than usual, despite contents unusually voluminous, for there are 950 pages. Owing to the fact that editorial work on the volume closed in May, some of the statistics are incomplete, but they relate to minor matters, and it is held that the greater promptness of publication more than balances the lack of them. As usual there are many reviews and technological articles of permanent value, prepared by W. R. Ingalls, F. W. Parsons, Frederick Hobart, J. T. Glidden, Robert H. Richards, J. F. Kemp, and other authoritative writers. It is not necessary to emphasize the value of this publication, for it has become indispensable to those engaged in the various branches of mining. The editor, Mr. W. R. Ingalls, is to be congratulated on the timeliness, completeness, and excellence of the book. It is for sale for \$5 by the MINING AND SCIENTIFIC PRESS.

'Electricity in Mining,' by Sydney F. Walker. D. Van Nostrand Co., New York. 380 pages.

This is a comprehensive book written by an engineer engaged for 30 years in the practical application of electricity to mining work. Among the subjects treated are signals, telephones, and electric lighting apparatus in use about mines. A chapter is devoted to the generation of electricity economically; another to the principles and practice of the distribution of electricity as it is applicable to mining. The best electrical machinery used in mining is described and information is given whereby managers of mines may obtain an idea of the power required for different kinds of mining work; how that power should be delivered, and how they know when they have the proper amount. Another useful chapter is that in which are given a few simple rules for the discovery of causes of failure in electrical apparatus. The author says that he has in view "the possibility that the mine may be situated hundreds of miles from everywhere, that the engineer in charge of the apparatus may have only himself to depend upon, and that he may be obliged to depend upon rough and ready apparatus in order to keep things going." The book is well illustrated and ought to be most useful to mine engineers, superintendents, and managers.

For sale by the MINING AND SCIENTIFIC PRESS; price \$3.50.

Publications Received.

The General Index to the Publications of the California State Mining Bureau has just been issued. This is a most valuable bulletin of the contents of the large number of reports, bulletins, and maps that have been published. It is listed as Bulletin No. 46, and was compiled under the direction of State Mineralogist Lewis E. Aubury.

'The Land of Sunshine' is the title of an attractive handbook of 446 pages, describing the resources, products, industries, and climate of New Mexico, and compiled by Max Frost and Paul A. F. Walter. The book is handsomely illustrated and contains chapters on the geography, geology, and mineral resources of the Territory. Published by the New Mexico Bureau of Immigration.

Editorial.

ALTHOUGH the statement that Mr. Roosevelt intended to become editor of the New York *Tribune* was unauthorized and untrue, it does not seem wholly preposterous. When we think of the influence that a big paper edited by a man of Mr. Roosevelt's character and energy could have on the thought of the country, we regret that it is not among the probabilities. It has been said, also without authority, that the President of the United States might become President of Harvard University, and to be the successor of Mr. Charles W. Eliot is an honor second to none, not even the Presidency of America. Nevertheless, we are of the opinion that a forceful man of high character and wide experience in public affairs could make a daily paper a greater educating medium than any university in existence.

COPPER is weakening and copper mining shares are depressed. In consequence, several small mines have been shut down and the operations of the larger companies are curtailed. It is stated that the Amalgamated Company sold a large consignment of copper at 15 cents, and that producers are timid. Certainly, buyers have been withholding their orders and as production continues there will be an accumulation of stock, endangering the stability of the market. It is likely that copper will be very weak for a while, but there is every reason to feel confident as to the future. Industrial depression will have to be severe and world-wide before the market can stay at anything like 15 cents. We expect to see the metal again at between 20 and 25 cents, that is, in the course of a year or so, after a period of unsteadiness. In the meanwhile copper that costs anywhere near 15 cents to produce had better be kept underground.

THE SCHOLARLY ARTICLE by Mr. F. Lynwood Garrison will be appreciated by mining geologists. In the course of his description of the occurrence of metallic sulphides in the tufts of Santo Domingo, he refers to similar occurrences elsewhere and draws attention to a type of ore deposit that is well worthy of closer study. Some of our geological friends could contribute supplementary observations and we hope that they will do so. It is likely that portions of the San Juan formation, consisting of tuff and breccia, in southwestern Colorado, were laid down in water, that is to say, the volcanic dust dropped into a lake and when consolidated became a rock the origin of which, therefore, was in part volcanic and in part sedimentary. The present writer remembers seeing a piece of rhyolite containing fossils, and thus eminently suited to deceive an unwary petrographer. It came from Nevada, and consisted of the

fine product of explosive volcanic energy that had fallen into water and had become consolidated under conditions permitting of the enclosure of plant remains. The successful exploitation of ore deposits in the consolidated tuffs of Colorado and Nevada adds another to the many rocks in which gold is found.

HYDRAULIC MINING is not as important a branch of gold mining as it was a few years ago, but in certain localities it continues to exemplify the effects of geological action in the past and of human activity in the present. At Cariboo, in British Columbia, a former channel of the Quesnelle river is being mined close to the existing river-bed, the two channels being separated by a narrow rim of rock. Mr. Douglas Waterman contributes an excellent description of the deposit and the manner in which it is being mined. Incidentally, mention must be made of Mr. J. B. Hobson, the engineer under whose skillful management the Consolidated Cariboo Hydraulic Mining Company has been enabled to operate so successfully.

Lost Bullion Spanish Mines.

THE STORY told in a court of law at Denver proves the Lost Bullion Spanish Mining Company to have been an imposture of the worst kind. Last week, by the verdict of a jury, eleven men were found guilty of a conspiracy to use the United States mails for fraud. Several of the defendants, at least two of them, were mining engineers in good standing, and to them conviction is an indelible disgrace, removing them from the ranks of the reputable members of the profession. The case was brought to trial by the Post-Office Inspectors and among the chief witnesses for the prosecution was Mr. Waldemar Lindgren, whose services were loaned by the Geological Survey to the Post-Office Department.

Briefly, a prospector named Du Bois claimed to be the discoverer of an ancient Spanish mine, first found by an aged Yaqui Indian. It was stated that big quantities of silver had been taken from these cavernous workings by the Spaniards before an Indian uprising had driven them from the country. To bolster this yarn, the promoters engaged mining engineers to make a pretended investigation and to certify as to the amount of ore available. A confession obtained by the postal inspectors from Du Bois punctured the soapy film of falsehood. It was proved that in the preparation of their glowing prospectus, the promoters hired a newspaper man named Lindsey, who used large patches of Prescott's history to heighten the interest of the descriptive matter distributed through the mail. The deed transferring the property proved to be in a fictitious name. A mining engineer testified that his report had been garbled and his samples doctored. Another, whose name it is a pleasure to mention—Henry Edwards—was asked to act as consulting engineer; he went to the alleged mine and refused to make an examination. Among those convicted, one mining engineer "was tired of making examinations for other people" and preferred a large block of stock. He

demanding and obtained 200,000 shares, which proved his undoing. For the sake of giving them a market value, he lied. To raise \$50,000, the sum of \$5,000 was spent in publishing the same kind of alluring statements and pseudo-scientific bunkum that anyone can read in dozens of newspapers today or tomorrow, especially in the Sunday editions of big dailies and on the advertising pages of religious papers.

When the agents of the Post-Office Department went to the alleged ancient mine, they found a large natural cave in limestone and they also discovered a big fraud. In order to get scientific opinion as to the nature of the hole, Mr. Lindgren was requested to make an examination, the result of which was conclusive. To combat this testimony the defence engaged a Professor Lindermann as an expert witness; he talked a lot of balderdash about stalactites and lime formations, all in the sort of language that parodies science and blooms on the pages of prospectuses designed for the illiterate. To prove the absurdity of this 'professor's' statements, our friend Mr. Philip Argall was put on the stand. Thus in the end the whole tissue of absurd lies was swept aside, with the result that the jury found all the perpetrators guilty.

We have told the story at some length because it exhibits a phase of mining that cannot be too clearly exposed.

Of course, this is not business but cheating; nevertheless, there is much of the same sort of thing in progress at the present time, and it is an inevitable concomitant of speculative excitement such as has marked the past two years. 'Ancient workings' and 'lost mines' are nothing new; they have been used over and over again by irresponsible schemers. We read in the Australian papers just to hand that the Big Hole Exploitation Syndicate secured \$50,000 from "prominent city men" in New South Wales by representing a strange excavation in sandstone as an abandoned mine. The very name 'Lost Bullion Spanish Mines' is eloquent of deception and the flamboyant twaddle of the prospectus should have been a warning also.

But what of the mining engineers that lent their names and that of an honorable profession to this wretched swindle? The public has a right to speak bitterly of men who, under the pretense of being skillful geologists and experienced miners, sell themselves to the predatory promoter. We hope that this case will be a warning to others tempted to take stock in mining companies instead of regular fees; that way lies the road to perdition. Avoid contingent fees as you would a direct bribe, for they undermine professional integrity and excite the cupidity of which none of us is wholly devoid. One more comment may be made: We wish that the postal authorities would publish the names of the newspapers and periodicals, some of them posing as advisors to investors, that accepted the advertisement of the National Securities Company—a beautiful name for the purpose—and the Lost Bullion Spanish Mines Company. These advertisements were lures on the very face of them; that is, anyone having the least knowledge of mining could detect them. Knavery of this kind is made easy by the prostitution of the press.

By the Way.

In a recent issue of *The Evening Post*, New York, we find the following interesting account of the Hawaiian volcanoes:

To make the ascent of Haleakala one must go by train along the coast from Kahului to Paia and there take carriage to the Haleakala ranch, which lies in the foothills at the base of the great mountain. From here it is a 10-mile ride over a winding rough trail up the side of the mountain to the summit. All the lower stretches of the mountain are covered with green, and thousands of cattle find pasturage on the hillsides. The land is broken with deep gulches, marking old lava flows, and the horses pick their way gingerly over the slippery footing. As one rises, the outlook is superb. On the level isthmus connecting the two halves of the island, the cane fields are seen marked off like a checker-board. Beyond the white line of surf and the curved beaches, the waters of the Pacific stretch away to the horizon. We reached the ranch house at Olinda at 4 o'clock in the afternoon, after riding for an hour through a blinding rainstorm. Two hours later, within three miles of the summit, we saw a sunset more than a thousand feet above the clouds. The sides of the mountain were bare and covered with broken stones, old lava runs, and bits of broken dried wood where once scrubby undersized trees had grown.

It was 8 o'clock and pitch dark before we reached the edge of the crater. We only knew it was the summit because the horses refused to go any farther. They had walked to within a couple of yards of the crater walls, which drop sheer down 2,500 ft. The last hour of the journey we could not see five feet beyond the horses' heads, and depended wholly upon the sagacious sure-footed animals to find their own way; they kept the trail unerringly.

That night it was so cold on the summit that, although we had tents and blankets, we found it impossible to sleep comfortably, and spent the entire night seated around a fire, swathed in blankets and sweaters. The night was as still as it was cold and clear. The sunrise the next morning was a gorgeous effect. The crater of Haleakala has a circumference of 20 miles and an area of 19 square miles. A score of cones from 300 to 1,000 ft. in height dot the floor, while from out the one-time cauldron lead two gaps, once the vents of lava flows which cover the eastern and southern flanks of the mountains. The impression is one of rare desolation and grandeur.

The active crater of Kilauea, on the side of Mauna Loa, is one of the most comfortable volcanoes to visit. One may do it in white canvas shoes with perfect ease. There is a fairly well appointed hotel on the edge of the crater, and one may easily walk in an hour the three miles from the top of the crater's edge to the smoking pit, Halemaumau.

Active volcanoes exist on the island of Hawaii, but even tradition gives no account of any elsewhere in the group. And on Hawaii, volcanic activity has been confined, within modern times, to the summit and slopes of Mauna Loa, with the exception of an eruption of Mount Hualalai in the year 1801. Eruption in the crater of Kilauea at 1,000 ft. elevation, and in that of Mokuaweoweo, at the summit of the great mountain, 13,675 ft. high, together with flows of lava from points about the periphery near the summit, all occurring at irregular intervals of years, constitute the lively features of Hawaiian volcanic phenomena. The people of the island have not the slightest fear of their volcanoes. The mountains of the island are so large and the flow of lava is so sluggish after it has been moved some distance, that peo-

ple in any of the inhabited parts of the island could hardly be taken by surprise by an invasion of the molten rock.

Records are extant of more than a score of eruptions upon Mauna Loa in the nineteenth century. The lava flows came from various points near the summit, and some of them lasted many months. One in 1887 and another in 1899 made magnificent displays, which were easily and safely accessible to view at short range, and drew large numbers of spectators from all over the islands. On such occasions steamboat excursions to the nearest landing are always hastily organized, so that the scene may be witnessed before it becomes played out.

The flow of 1887 continued for more than a fortnight, down the slopes, 30 miles to the sea. In places the fiery stream spread out to a mile's width, and, passing over abrupt declivities, formed cascades of flaming debris. Fire fountains played all along the moving mass. This eruption, within the seventeen days that the flow lasted, was signalized by nearly 400 earthquake shocks, none of which did heavy damage.

The flow of 1899 started, by a peculiar coincidence, on the second Fourth of July after the annexation of Hawaii and continued for three weeks. Those fortunate enough to get within near view of the diversified manifestations, which involved some arduous mountain climbing, were fully rewarded. The eruption, according to guesses made by observers, appears to have started within 3,000 ft. from the summit, but eruptive cones of great size developed at various distances farther down for two or three miles. Some of these were mighty fountains, throwing not only fused material, but huge boulders, to a height of 50 ft. At the highest vent the eruption formed a crater, which assumed the form of a mound 150 ft. high, over the rim of which four streams of lava poured to merge at the base. A curious development in a lava flow is that as it takes its way it forms a tunnel of congealing crust through which the purely fluid matter runs for a long distance concealed. Here and there along the route the accumulated gases produce minor eruptions, causing fire fountains. In the last-mentioned flow there would be visible at once from a single point of view several of these eruption cones, ranging from 100 to 300 ft. in height.

Kilauea forms a cavity in the mountain-side with walls on three sides from 300 to 400 ft. high. Its area is about four square miles; circumference, 7.85 miles; extreme length, 2.93 miles; extreme width, 1.95 miles. The principal focus of activity is near the middle of the main crater—or what Captain Dutton, who wrote a scientific report on Hawaiian volcanoes for the United States Government in 1884, conveniently called the caldera, to distinguish it from the eruptive vents within its confines. Halemaumau, meaning the house of fire, is the name given to the principal cone, whose interior in periods of high activity constitutes a lake of molten lava.

In the intervals between the more violent periods of Kilauea, lasting sometimes for years, intense heat is retained in all of the lava vents as well as throughout miles of fissures, extending in various directions upon the floor of the caldera. Any inflammable material exposed to these openings takes only a few moments to become scorched or ignited. Odd formations of lava are found all over the floor, including the caves and bridges, within or under which the spaces are large enough to shelter a crowd. One particular cavern is a vault-shaped place entered through a hole broken in its roof. It is ten feet deep and about fifteen feet each way laterally, and its temperature is usually so high that few can remain inside it more than a few minutes.

Personal.

E. W. PARKER is in San Francisco.

F. L. BOSQUI has returned from Tonopah.

JAS. W. ABBOTT, of Pioche, is in San Francisco.

W. B. MILLIKEN is in Denver, on a visit from Nevada.

S. V. TRENT, of Salt Lake City, was in Denver recently.

J. A. AIVERETT is examining mines near Parral, Mexico.

J. V. N. DORR, of Denver, is at Deadwood, South Dakota.

T. BRUCE MARRIOTT is examining copper mines in Norway.

W. DE L. BENEDICT is expected in San Francisco during October.

F. B. REECE is spending a short time at his home near Liverpool.

FRANK A. KEITH, of the Montana-Tonopah mine, is on a visit here.

L. HUNDESHAGEN has left London on his way to the west coast of Sumatra.

H. DE C. RICHARDS has been inspecting mines near Deadwood, South Dakota.

W. E. WAINWRIGHT is manager of the Broken Hill South mine, in New South Wales.

E. E. BENJAMIN has returned to San Francisco from the examination of mines in Idaho.

J. P. SIDWELL has returned to Chicago from a visit to the Atlas mine, at Ouray, Colorado.

JAMES E. HYSLOP is manager for the new owners of the Palmilla mine, at Parral, Mexico.

MILNOR ROBERTS is superintendent for the Alaska Galena Co. near Ketchikan, Alaska.

L. H. GREENE, who has been operating in Humboldt county, Nevada, is now at Berkeley.

NORMAN CARMICHAEL, of the Arizona Copper Co., is in San Francisco from Morenci, Arizona.

OSCAR A. ANDERSON has been appointed instructor in the Dakota School of Mines, at Rapid City.

T. B. GREENFIELD has been appointed assistant engineer at the Yusspensky mine, in Central Siberia.

CHARLES L. POINDEXTER is manager for the Cia. Minera de Oro de Guarisamey, in Durango, Mexico.

H. A. SHIPMAN has been appointed consulting engineer for the United Rico Mines Co. of Rico, Colorado.

WILLIAM CAMPBELL has been promoted to an adjunct professorship of metallurgy in Columbia University.

FRANCIS W. BOSCO, mill manager for the Great Mogul Mining Co., has returned to Denver from New York.

JUNUS W. JOHNSON and HERBERT C. ENOS have opened offices at the Iturbide Hotel, Mexico City, as consulting mining engineers.

L. M. TERRY was held up and shot in the leg near Sta. Eulalia on August 16. The wound was not severe, and he is recovering rapidly.

ARTHUR S. EAKLE, professor of mineralogy in the University of California, has returned from an interesting geological reconnaissance in Alaska.

W. G. ANDERSON, formerly mine superintendent for the Dolores Mines, Ltd., in Chihuahua, is now manager for the Iona Gold Mining Co., at Smuggler, Colorado.

Obituary.

COMMODORE PERRY CRAWFORD died at Santa Rita, near Silver City, New Mexico, August 23, 1907. Owing to a mis-step, he fell into a shaft and was instantly killed. Mr. Crawford has been associated in the development of the Southwest for the last forty years, through merchandising, banking, and mining. He was a man of ability and unquestioned integrity, and one whose active and practical sympathy and kindly manner will be remembered by many, and whose loss will be keenly felt by all who knew

him. Mr. Crawford was born near East Liverpool, Ohio, in 1845. He enlisted in the Union army at the commencement of the war, at the age of seventeen, and served with honor until mustered out after Lee's surrender, taking part at Harper's Ferry in the siege of Vicksburg, and in Sherman's campaign. His body was fitly shrouded in the stars and stripes—for the long hard battle, especially of his later years, was done; and he had earned his parole. He leaves a wife, a son, in his senior year at the University of California, and six daughters.

General Mining News.

ALASKA.

News has been received in Ketchikan of a good strike on the Julia group in Yankee basin, at the end of an 800-ft. tunnel, 450 ft. below the surface. This property is under bond to John G. Heid for \$60,000, the bond expiring November 1.—Work has been temporarily suspended at the Sea Island property.—Sam Gourlay has taken a contract to drive the lower tunnel in Beaver Mtn. for the Sultana company.—Twenty-seven men are working at the Moonshine property on Prince of Wales island, under Milnor Roberts.

ARIZONA.

COCHISE COUNTY.

Work on the North Bisbee Development Co.'s property in Tombstone canyon has been temporarily suspended, to retimber the shaft.—The Shattuck-Arizona continues to produce 400 tons per day, and work is progressing on the 900-ft. level. The winze on the Leo claim, 800-ft. level, is still showing good ore.—The shipments from the Denn-Arizona average about 50 tons per day, coming principally from the 1,100-ft. level. A station will be cut at the 1,200-ft. level.—A force of miners has been put to work on the new discovery made by William Fourr, 20 miles west of Benson, and are sinking a shaft in ore. Lead ore has been discovered and opened between 30 and 40 ft. deep in that vicinity, and the lead carbonate region there is known to be about two miles square.—A strike made by the owners of the Seherer property recently, at a depth of 45 ft., of sulphide ore that assayed from 30 to 35% copper, has caused excitement this week. This property was bought by San Francisco parties some five weeks ago. Emile Allen is manager. They have shipped two carloads of ore already to the Copper Queen smelter at Douglas, and have about two carloads more on the dump. On account of the judgment given in the district court an order of sale has been made of the property of the Cochise Consolidated Copper Co., in the California mining district, in the vicinity of Paradise. The judgment was rendered in favor of Madison L. Larkin of Scranton, Pa., who held a trust deed for the property to secure a loan in the sum of \$22,000. The property of the company that is to be sold consists of a group of 13 claims, located in the heart of Paradise district, and is said to be one of the best groups in that district.

GILA COUNTY.

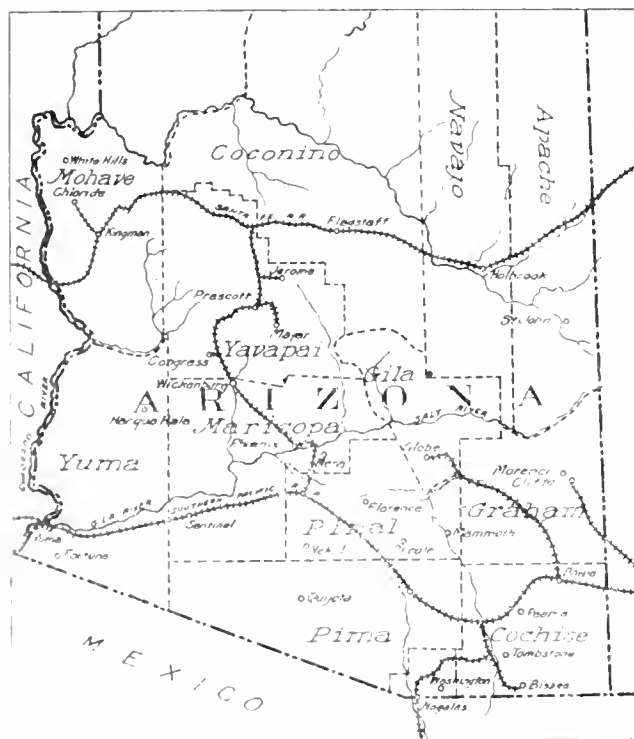

(Special Correspondence).—A good strike has been made on the property of the Superior & Boston Co., at Globe. Rich copper carbonate ore has been uncovered in the 335-ft. level of the Limestone shaft. The ore is similar to that found on the Black Oxide and Great Eastern claims and other properties of the district. The most encouraging developments on the group of claims belonging to the company are in the Black Oxide, where some 7% ore has been found. Indications point to a continuation of the high-grade ore, and the deposits show no signs of giving out. The company is erecting two lines, one at the mine and the other on the Arizona-Commercial railroad. The Great Eastern shaft is down 335 ft. and will be sunk 125 ft. more to the water-level.—The Old Dominion company should make a record production of copper, the present daily average output of the smelter being 450 tons.—A large amount of ore is being hoisted, and good progress is being made in development and construction work. The big winze is going down steadily, and by October 1 it will be completed to the 16th level. Coke and other supplies are arriving, assuring continuance of the present activity and prosperous times for Globe. No. 5 cross-cut west on the 14th level has encountered sulphide ore of about the same grade as at other points on this level, going about 10% copper. The new cross-cut is being driven slowly on account of the ground being heavy and wet, requiring careful timbering. The sulphide vein on the 14th level has now been partially opened by cross-cuts and drifts to a total length of 800 ft., the ore running well and having an extreme width of 80 ft. The average copper

value is about 10%, and in the west stopes and drifts shows an increasing percentage of sulphur so essential to the converter process of smelting. The winze will reach the 16th level at a depth of 1,235 ft., where it is expected the ore-shoot will be found to be wider even than it is on the 14th level, and to carry more sulphur in the ore.

Prescott, Sept. 1.

MARICOPA COUNTY.

Franklin W. Smith has recently reported on the property of the Southwestern Development Co. for the Phelps-Dodge people, and money has been raised for the development of the property, work on which will be resumed at once. The ore in this mine has some tellurium, which was not discovered until a short time ago. The orebody is large and the average value is good, and with proper management it should make a mine.—A plant for the treatment of low-grade copper ores is now in operation, reducing the ores of

Map of Arizona.

Cornelia Copper Co. at Ajo, 50 miles south of Gila Bend. It is known as the Anderson process and the plant is producing copper direct from the ore at a low cost. Edward L. Anderson, the inventor, is supervising the plant at Ajo. These people expect to erect a plant that will produce 2,000 lb. copper per day. The capacity of the present plant is 400 lb. per day.—Hoisting machinery has been ordered for the Greenstone mine, which is showing up well as development progresses. At the bottom of a 60-ft. shaft is a 60-ft. cross-cut, and driving along the vein each way is being done. In these drifts, each of which is 20 ft. in, there is some ore.

PINAL COUNTY.

Thos. Haley recently paid \$40,000 for interest in the Calumet mine on Mineral creek. Thos. F. Weedon of Florence negotiated the sale, and the Consolidated Big Lead and Calumet Mining Co. are the purchasers, and they will do extensive improvement.—J. H. McCabe has acquired 27 claims, including the Silver King mine, in addition to several millsites. The smelter at Price station on the Southern Pacific railroad is also owned by McCabe and associates. It is the intention to concentrate ore from the numerous mines of the group and operate them in connection with the smelter, which will also receive custom ores. The present metallurgical plant comprises a complete sampling works and a 20-ton stack, built originally for experimental purposes. A 250-ton stack is to be built to treat a large tonnage of custom ores.—W. V. Elliott, superintendent of the Wessell Copper M. & M. Co., is working six men on the

American Boy mine, situated about two miles north of Toltec, on the Southern Pacific railway. The workings at present are 100 ft. deep, the sinking being carried on for the purpose of catching the vein that shows in several other workings on the property. The American Girl, another of this company's properties, is an extension of the American Boy and carries approximately the same ore. The formation is schist and porphyry with large firm rhyolite dikes crossing it. They also have 12 claims on Arizola Mtn., which are close to the railroad and are showing up well. The Wessell Copper M. & M. Co. is composed of St. Louis capitalists and mining men who organized last winter to take over these properties after thoroughly investigating them. Vanadium has been found in a vein on claims six miles from Kelvin, belonging to Platt & Foss.

It is thought that the reorganization of the Troy-Manhattan company will soon be effected. The terms are that the men who will have control of the new company are to spend \$750,000 in development work and machinery, in return for which they will receive 60% of the stock of the old company.

YAVAPAI COUNTY.

The 160-ft. shaft of the Treasure Vault mine has been wrecked by the excessive amount of water, due to the heavy rains, which formed a torrent that swept down on the shaft, overturning the water-tank, and tore away the timbers in the shaft, carrying them to the bottom in a hopeless mass of wreckage. The whim narrowly escaped being carried to the bottom by the water. Some of the richest gold ore mined in the district was taken from the Treasure Vault. It is owned by John Daly of Crown King and R. H. Row of Prescott. The shaft will have to be entirely re-timbered.—W. H. Knight, president and general manager of the Knight Copper Co., is enthused over a strike of manganese ore made in the new working shaft on the Owl group of mines, about three-quarters of a mile south of Humboldt. The orebody, which was struck at a depth of 10 ft. in the shaft, is 4 ft. thick.

YUMA COUNTY.

Thomas Finnegan will have charge of the development of the Copper Whale group of claims, near the Victor and Bell Crown. A contract will be let for a 100-ft. shaft. New York and Los Angeles people are interested in the company.—A. E. Wiley of Los Angeles has been examining properties in the Tank Pass district.—E. A. Haggott is examining the Ironwood & Arizona property, and will advise as to new development work. The shaft is down about 300 ft. and 15 men are employed.—The Victor and Bell Crown shaft is down 250 ft., having been put down under contract by Andreas Olivares.—Development work on the Harecuvar Copper Co.'s property, near the Ora Cobre, has been started, being financed by Philadelphia capitalists.—Work has started at the Hercules property, after a two months' shut-down. This mine is near Salome and gold ore has been struck.—W. C. Price of Los Angeles has purchased six copper claims in the Silver district from Mrs. T. M. Hart of Cibola, the price being \$10,000.

CALIFORNIA.

CALAVERAS COUNTY.

Good reports of the Hamby mine, near Golden Gate, operated by the Viking Gold M. Co., are brought by C. E. Engstrom. Ten stamps are dropping, the ore being stoped from the 200-ft. point. The shaft will be sunk 100 ft. farther, and ten more stamps will be added. Eighteen men are employed.

NEVADA COUNTY.

The London Exploration Co., represented by Charles A. Derby, will pump out the Independence mine, on Wolf creek, near the lower Plumbago mill, in order to examine it. An incline is down 180 ft., and a vein is supposed to be showing in the bottom.—A good many improvements will be made in the equipment of the Ironclad, including a 10-stamp mill, a three-compartment shaft, and a 16-in. Cornish pump. Several unsuccessful attempts have been made to keep the water out of the workings with an inadequate pumping plant.—An important strike has been made in the California mine, on Deadman's Flat, where a

vein of good milling ore has been discovered in a 25-ft. raise from the south drift. The shaft is 250 ft. deep. Grass Valley people own the controlling interest in the company.—All the mines closed for Labor Day, throughout the district.—A company will take over and develop the Young America group of claims at French Corral.—The shoot recently struck in the Ethel continues to look well and the company is trying to acquire contiguous ground.—The Marcotte mill will be crushing within a month, and the five stamps on the Williamson are already dropping.—J. O. Jones, in charge of the small crew working at the Old Channel gravel mine at Blue Tent, will not concede the 8-hr. day demanded by the men who recently walked out.—J. C. Nash and John Meyers are making another examination of dredging ground at Greenhorn and the country around You Bet.—Some rich ore has been brought to Grass Valley from the Morning Star mine, which the James brothers are developing on Randolph flat. The rock came from the bottom of a 125-ft. shaft.—The vein at the Delhi mine is looking well, and the water supply is now adequate, as the second ditch from Bloody Run has been finished. Hamilton Eddie is the superintendent.—The Pittsburg Standard M. Co. will build a 5-stamp mill at the Norambagua mine, to be used in testing ore taken out in the process of development.

SHASTA COUNTY.

A statement is credited to Paul Heroult to the effect that the electrical furnace on the Pit river will not turn out any more pig iron, as at \$30 per ton there is not much profit in it. Instead, the furnaces will be run continuously making ferro-silicon, for which a higher price can be secured from the steel-casting plants. As soon as the railroad is completed past the smelter, which will be in about three months, pig iron will again be produced.—The No. 1 furnace at Kennett has been shut down for extensive repairs and alterations. It will be changed to a water-jacket-top furnace.

SIERRA COUNTY.

(Special Correspondence).—The lower cross-cut tunnel in the Tightner is being driven steadily ahead. The rock has softened during the last 50 ft., and more rapid progress is being made. Ore is being extracted from the main vein.—Work has been resumed on the Oriental, but the scarcity of men is retarding operations.—The rich strike recently made in the Rainbow is improving with development. Milling ore is being blocked out.—The Doile has been reopened by J. Freeborough, and will be systematically developed.—Construction work is under way at the Red Star. Underground operations will be resumed when winter starts.—A South Dakota company will develop and operate the Yellow Jacket group of quartz claims. Several promising veins have been exposed in prospecting the claims.—The Alma Mater group has been bonded by Oakland parties and will be developed at once. The claims contain rich quartz, and are situated on Wolf creek.

Alleghany, Aug. 31.

TRINITY COUNTY.

The Dorleska mill has started, treating ore taken out by lessees; five stamps will be kept dropping for some time. This property is at an elevation of about 7,000 ft.—It is thought that the first furnace at the Balaklala smelter will be blown in about December 1. The plant is nearly completed; three furnaces are in place, the 250-ft. smokestack is done, and the cables are being stretched on the towers of the aerial tramway. The four furnaces will handle 2,200 tons of material per day.

TUOLUMNE COUNTY.

The strike in the Omega mines continues to attract attention, as the ore is holding well. The rich shoot was struck in a cross-cut on the 300-ft. level. This property is on the west side of Table Mtn., two miles from Jamestown, not far from the old Rawhide mine. C. W. Ayers is the superintendent and a large shareholder.—Richard Sutton is in communication with Eastern people, to whom he expects to sell the Pereira mine. They will make an examination

of the property next month.—The App, Shawmut, and Jumper mills are running steadily.—Some good ore from the old Spring Guleh mine near Hunter canyon is on exhibition in Tuolumne. The Soulsby and Confidence, also on the east belt, are showing some good ore.—The Dreisam property is being cleaned out, preparatory to starting up.—The Gross mine at Tuttletown, owned by Fred Sutton of Sonora, is being worked under lease by Phil Rowe.—The Red Hill mine on Bald Mtn. has been unwatered and the 100-ft. level cleaned out. A five-year lease on the property has been given to Simon Hummel and Jim Kerr, by William Lewis.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—An important strike of silver-lead ore has been made in the adit in the Mary Ann mine. The vein is 16 in. wide and assays well.—Ore is being extracted from the Tobin, and is being developed on the six main levels; 200 tons of high-grade rock is sacked for shipment to the Denver smelter, while the lower grade material is being handled at the Wilcox mill.—A body of ore carrying gray copper and silver has been struck

ore.—Work has been resumed in the Mohawk tunnel of the Georgetown district, recently purchased by the Accord M. & M. Co. This adit is in 760 ft. The Two American Sisters company will furnish the power. J. J. Cully is president and James A. Mears is secretary, both of New York City. This tunnel was started in the early seventies to tap the Choctaw ore, and other Saxon Mtn. properties.—Jerome Smith is manager for the Democrat Mtn. M. Co., which is confining its efforts principally to the Moline tunnel, where driving is being done on the Beecher and Boston lodes. The aerial tramway from the Moline tunnel has been repaired.—Some good ore has been uncovered on the Nab-of property on Columbian Mtn., near Silver creek. Two levels have been driven 1,300 ft. and bunched ore has been exposed.—The Kalamazoo tunnel is being driven to cut the Snowdrift vein, and has about 100 ft. more to go. Caves in the tunnel have given a good deal of difficulty.

OURAY COUNTY.

(Special Correspondence).—The Atlas M. & M. Co. has recently increased its mill from 10 to 20 stamps, and will shortly increase to 40 stamps. The cross-cut tunnel is in 2,100 ft.; 425 ft. from the entrance they encountered the Crown Point vein and the Atlas vein 2,000 ft. in. These veins are being worked extensively. During the month of July they secured from the plates \$4,500, and \$4,000 worth of concentrates. The average assay values of the mine is \$13, and the pay-streak about 30 in. in width. It is estimated that with 20 stamps they will be able to mine and mill the ore under \$5 per ton, and with 40 stamps the milling cost will be 80c., and the mining cost not to exceed \$3.50 per ton; 4,200 ft. east of the Atlas claim and on the Atlas property the San Pedro tunnel opened up recently a silver vein at a depth of 1,200 ft. from the surface, three feet of ore averaging \$25 to \$30 per ton. J. P. Sidwell, of Chicago, is president.

Ouray, Aug. 30.

SAN JUAN COUNTY.

A decided shortage of miners is noticeable throughout the San Juan region, and the supply of laborers seems to be about exhausted.—Most of the mills in the region are running to full capacity. The Iowa mill is producing about a carload of concentrate per day, and the Green Mountain and Little Dora mills are running. The larger plants, including the Silver Lake, Gold King, Old Hundred, and Hamlet, are producing steadily; the Gold Prince will be dropping stamps as soon as some electrical machinery arrives, and the Mogul is only awaiting the arrival of a roaster.—Louis Resouehes has driven a tunnel 110 ft. on his property and has recently encountered a strong vein.—The tunnel on the Wonderful group in Mill gulch, above Chattanooga, is in 1,500 ft., of which 1,100 ft. is on the vein. Streaks of high-grade material have been encountered at various points. T. Jay Hurley is the manager.—The Elsinore vein has been cut in the No. 5 tunnel of the Hamlet company at Middleton, 430 ft. below the surface. The ore contains lead, copper, and zinc, and the tunnel will be continued 750 ft. to the Hamlet vein. The mill is treating 75 tons of ore per day that is taken from the drifts, as no stoping is required to produce this amount. More than 7,000 ft. of driving has been done during the past year, under the management of William Lloyd.—E. C. Condit has taken a lease and bond on the Ariadne property, near Gladstone, in Cascade gulch, from Alfred Hles.—The shaft on the Molasses will be drained as soon as the present 300-ft. contract is completed.—Some good ore has been struck in the Gold Lake group of eight claims, owned by Louis Fritz and Al Rennis, in Spence basin.—The tunnel of the Trilby Gold M. & M. Co., on King Solomon Mtn., is in 1,570 ft. and is expected to cut the main vein at about the 3,000-ft. point. A Rand compressor has been installed that will be operated by electric power. Martin Hawk is the superintendent.—Work has been resumed on the Senior Warden property, adjoining the Molasses mine on Sultan Mtn. The tunnel is in 500 ft. and the ore should be cut 300 ft. farther in. J. S. Herr is the manager.—The St. Paul, in the Red Mtn. district, now operated by the Ross M. & M. Co., has shipped another carload of copper ore.

Map of Southwestern Colorado.

in the lower levels of the Waukegan. The vein is 12 ft. wide. A small streak has also been found in the upper workings.—Work has been resumed on the Domingo group, and the lower cross-cut tunnel has been driven 400 ft. The company is being financed by Georgetown business men.—A vein averaging 11 in. wide has been struck in the Malen tunnel on the Scotia Mines group. The ore carries silver and lead, running about \$150 per ton.—A strike has been made in the North Star, on McClellan Mtn. At a depth of 200 ft. a four-inch vein running well in gold and silver, was struck. A body of ore has been struck in the adit on the Faurot lode, in the Delaware, 200 ft. from the portal. The vein is heavily mineralized and is four feet wide.—Good smelting ore has been encountered on the third level in the Bellevue-Hudson. The vein is seven feet wide. The mine will be operated by electricity, power being obtained from the Two American Sisters M. Co.—Considerable development work is under way in the American Sisters. In the Headlight shaft, the east drift from the 275-ft. level has opened up an 18-in. vein carrying silver. The mill is running on full time, and a large amount of lead, iron, and zinc concentrate is turned out.—Work will soon be resumed in driving the Golden Glory tunnel. The tunnel is expected to intersect some of the important veins of the district.

Georgetown, Aug. 15.

A strike of importance is reported in the Doric tunnel, on the Cram lode, 2,400 ft. from the portal. The ore comes from the back of the stope at this point, and carries gold, silver, lead, and zinc. Mill-test runs have been made on the

—A dozen men are engaged in sinking the 150-ft. shaft on the Iron Mask property in Maggie gulch, owned by the Intersection M. Co., for which J. E. Bowden is manager.

SUMMIT COUNTY.

The Silver Princess mine, one of the producers of the early days, is likely to soon excell all of its former records of production. Samples taken from one of the ore-shoots showed silver, lead, and zinc. High-grade milling ores are by no means infrequent in the Montezuma district, and the facilities for working them at a profit are soon to be at hand, if the recent activity of operators and large investors is to be regarded.—It is stated that the Kimberly-Wilfley mill at Kokomo is to furnish the model in a general way for the new Wellington mill, yet with important variations in some of the essential details. The special features of the Wellington mill will be close extraction and low costs. So thorough have been the tests that the Wellington officials are able to proceed with accurate knowledge of the nature of the milling requirements needed for their ores. The plant is to be situated on the eastern portion of the property, almost adjoining the property of the Reliance Dredging Co. This millsite is well selected, as a saving will be effected through the operation of a gravity tramway.

IDAHO.

SHOSHONE COUNTY.

The Missoula Copper M. Co. stockholders have voted to increase the capitalization to 1,500,000 shares of \$1 each. Robert McCormick reported that five stringers of copper ore have been struck, and a wagon-road built to the Independence tunnel so that machinery can be hauled to the property. An 8-drill compressor and motor will soon be installed.—The Snowstorm mill is treating 4,000 tons of ore per month, and 200 men are working at the mine. The new No. 4 tunnel is being driven 500 ft. vertically below No. 3.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence).—The tunnel on the Nevada Empress is in 900 ft. A winze has uncovered a four-foot orebody, and the company has decided to install a 10-stamp mill.—At the Goldfield Granite Mtn., the cross-cut tunnel is being driven to cut the vein at a depth of 500 ft. A second tunnel will soon be started.—The 450-ft. tunnel on the Richmond Gold Mtn. has cut out a body of lead and iron sulphide, containing \$15 per ton in gold. The 60-ft. shaft is in ore.—The shaft at the Nevada Frisbie is down 200 ft. in good ore. Several veins are being developed, and driving is under way.—The 10-stamp mill at the Bonnie Claire is running day and night on ore from the mine, but the highest grade is being shipped to Salt Lake for treatment. It is announced that the capacity of the mill will be doubled.—A large vein carrying some ore has been struck on the 800-ft. level in the Rattlesnake.—Some ore has been found in the May, and the vein is being developed.—The Oro Grande group is being developed by Rhyolite people. The lode is 12 ft. wide and the tunnel is in 110 ft.—The Blair group has been sampled by engineers representing Eastern parties.—The Wyman-Vyck Co. has secured a one-third interest in a group of copper claims near this point.—The Ohio-Linda Co. has decided to sink a shaft on Ohio No. 1, where some good ore has been found on the surface.—A vein containing gold, silver, and copper has been struck in the Rube Ryder group. Copper predominates with good silver values.—It is reported that a railroad will be built from this district to connect with the Las Vegas & Tonopah line.—At the Great Western much development work is being carried on, and an ore reserve is being blocked out.—The Lime Point continues to make a good showing with development.—At the Goldfield Mtn. quartz has been found containing wire gold. A tunnel is being driven to cut the lode at a depth of 600 feet.

Lida, Aug. 29.

LANDER COUNTY.

The shaft of the Reliance company's Little Gem mine is down 450 ft. on a 30° incline; 250 ft. of driving has been done on the 200-ft. level, 200 ft. on the 350-ft. level, and 100

ft. on the 400. John Tyree is the manager and Edward Cox is foreman.—The shaft of the Gold Quartz Co. is down 280 ft., and there is some milling ore on the dump. Copper indications come in about the 200-ft. point in the shaft.—Some good ore has been struck in the north drift on the 60-ft. level of the Bridal Wreath; four men are employed.—The Uncle Sam shaft is 65 ft. deep. F. E. Bowman is the manager.—An engineer has been examining the Bonanza group, now under bond to Schiele & Marion, for Salt Lake people.—The Silverside mine at Lander has recently been examined by several engineers.

LINCOLN COUNTY.

(Special Correspondence).—The incline shaft of the Nevada-Utah has attained a depth of 1,600 ft., and is still going down. Twenty-two other shafts and several cross-cuts have opened immense ore reserves. The company intends erecting a smelter near this city.—On the Prince, both shafts are below the 300-ft. level. In the bottom of No. 1, a cross-cut has uncovered a 40-ft. vein. The ore contains lead, silver, gold, and iron. The mine is equipped with a 40-hp. gasoline hoist and air-compressor.—Extensive development is under way at the Ohio-Kentucky. One shaft is down 310 ft., and another 340 ft. William Lloyd is superintendent.—The main shaft at the Last Chance is being sunk to the 500 level from the 250-ft. station. Some good ore has been encountered. E. F. Gordon is manager. Prospecting is going on at the Pioche X-Ray. Ore carrying silver, copper, and lead, and running \$15 per ton, has been found in the incline shaft.—A vein of fair-grade ore is being developed in the Mendha. The incline shaft is down 700 ft., and shipments of ore are being made to the Salt Lake smelter. The Nevada-Des Moines Co. is exploring the porphyry dike on its holdings. Good returns have been obtained from the outcroppings.—Simon Bamberger is preparing to sink a double compartment shaft on the Black and the Raymond & Ely veins. Good copper ore is being developed in the Bristol. Both shafts are in ore. Walter C. Brace is general manager.—The Ida May is being operated by W. A. Clarke, Jr. Some promising veins of low-grade copper ore are being developed.—At the Silver Horn group two parallel veins carrying silver, copper, and a small amount of gold, are being developed. The veins are about three feet wide.—The Southern Nevada M. & R. Co. has been organized to take over a group of 16 claims near this city. A small force will be engaged to develop the claims.—The building of the railroad has started a boom throughout this district, and it seems that Pioche will soon enjoy a measure of its oldtime prosperity, when it was one of the largest camps in the State.

Pioche, Aug. 19.

NYE COUNTY.

(Special Correspondence).—The Golden Anchor and Midway Extension have been consolidated, the former taking the property of the latter for 700,000 shares of its stock. The stock of the Golden Anchor has been increased from 1,000,000 to 2,000,000 shares: 170,000 shares of treasury stock will be put on the market at 20c. per share, for the purpose of paying off indebtedness and developing the properties.—It is reported that a large ore-shoot has been struck in the Belmont.—The outside districts, tributary to this city, are lively.—In the Bellehellen section 16 properties are being developed. On the Poles excellent ore is being sacked for shipment.—The shaft at the Nellie Bly has attained a depth of 37 ft., and some ore has been exposed.—At the Shasta and Aggie B. groups development is under way.—Ore has been uncovered in both properties.—Work has been resumed on the Cornforth, and the management states that shipping will commence at an early date.—In the South Klondyke district the Stormy Night and New Klondyke mines are showing up well. A small shipment of ore was recently made from the latter. The ore is principally silver-bearing with a little gold and lead.—In the Fairplay district several properties are being worked. The shaft at the Goldyke Reef is down 200 ft. A 50-ton Huntington mill is crushing the ore. Considerable water has been encountered and a pump has been ordered.—It is reported that the old Pactulus mine will be reopened by

Special Correspondence.

Mexico City.

*Denver Men Successful.—Santo Domingo Co.—Mining Near Ayutla.
—Activity in Jalisco.—Deal at Guanajuato.*

In the State of Sinaloa, about 80 miles east of Mazatlan, Hugh Swearingen and Fred Matthews, of Denver, together with a number of their friends in the railroad circles of Denver, have taken up about 500 metres along an extremely strong vein, rich in gold and silver, which was located by C. E. Parlin, whom they had grub-staked. They have organized the San Miguel Mining & Reduction Co. for operating the same, which will be under the management of Mr. Parlin. The vein is said to vary between 50 and 250 ft. in width and is but 30 miles from the line that the Southern Pacific is building. Near their property, at Santa Lucia, a Mazatlan company is operating the Piedad Anexas, which, with two years' development work, is in bonanza ore, of which the high-grade is being shipped while the low-grade is stored for the mill now in course of erection. The mill is to consist of stamps, plates, and Wilfley tables, with a cyanide plant for treating the tailing.

In the Hostotipaquillo district, State of Jalisco, the Santo Domingo Mining Co. is to be congratulated in obtaining the services of Patrick Fitzgerald as manager. Mr. Fitzgerald is an old Colorado man who for several years has been operating (in the Mascota district of Jalisco) the Lupita mines and mill for Frank Peck and others of Colorado Springs. Last fall Mr. Fitzgerald left Mexico for a while to try his fortunes in Nevada, but not meeting with the success he anticipated, he returned this spring to Mexico and has taken up the position mentioned above as offering more favorable opportunities than seemed possible at the Lupita mines, which have always proved, because of their situation and distance from the railroad, a very close proposition. The Santo Domingo, however, is but four or five hours' ride from Etzatlan, and almost adjoins the property of El Favor Mining Co., controlled by Makeever brothers. They have been opening up large bodies of high-grade ore having every indication of being a continuation of the famous Mololoa vein, now being worked by Carlos Romero. The Santo Domingo itself, on its Esperanza claim, has for several months been working on a four-foot vein, which is continually improving, and is now stated to be as good as the best in the famous old Hostotipaquillo district. In addition to El Favor the Makeever brothers have recently taken over the old Tajo mines of San Sebastian, north and west from Mascota, and in one of the best parts of the State of Jalisco, near the boundary line of the territory of Tepic. From points on the property the shores of the Pacific may be seen. The property is one of the oldest silver mines in this old camp, and the new owners will open up the vein by two adits that should cut it at 600 and 1,200-ft. depth, and plans are being prepared for a power-plant on the Los Reyes river, for the operation of a 100-ton cyanide plant as soon as the vein has been sufficiently opened. There are several cyanide plants already in successful operation in this district.

In the southern part of the State near Ayutla, Kent E. Keller, after several years' hard work on the holdings of the Carrizo Copper Co., has opened up sufficient ore to interest St. Louis capital in the erection of a concentrator and 50-ton smelter on the property; the material has been ordered, construction is under way, and it is expected that it will be ready for business in January next. This part of the work will be in charge of A. L. Waters, who

was formerly with the National Metallurgical Co., of Matchuala, San Luis Potosi, and who is now at Ayutla attending to the work. Mr. Keller has also obtained a concession for a power-plant on the Carrizo river, which it is intended shall furnish power for the mines, mill, and smelter, as well as light for the towns of Ayutla and Purificacion.

From Guanajuato comes the news of an important transfer of mining property. The Dwight Furness Co. has transferred the La Fortuna group of mines to the San Gregorio Mining & Railway Co., of New York, which is represented at Guanajuato by H. H. Miller. Capt. W. Murdoch Wiley is president. The ore is largely valuable for its gold, as well as silver. It is expected that the new company will also take over the control of the railroad from El Chorro to Marfil, where it connects with the Mexican Central.

Johannesburg, Transvaal.

Result of the Strike.—Lower Wages.—The Ticket System.—The Beer Bill.—Boer Ministry Withdraws it.—Chinese Labor.

During the past few days almost all the mine managers have been visited by delegates from the strikers, to find out on what terms they could come back to work. The delegations were informed that most of the positions on the mines were filled, and that at present only a few of the men could be taken on again. Of course, the old terms were asked for, but the managers pointed out that one of the first laws of war is that the victors dictate terms, not the vanquished. The terms given to the strikers are that for the present all underground contracting ceases; that miners 'bossing' hammer coolies or Kaffirs receive 16s. 8d. per shift, the number of laborers to be superintended to depend entirely upon the wish of the management; that machinemen receive £1 per shift for looking after three or four machines, while the exceptional machine men who 'boss' one section of the mine with five or six machines, are to receive about £35 per month. Trammers are to receive from 10s. to 15s. per shift. The delegations retired rather crestfallen, for these terms are in some cases less than half what the rates were before the strike commenced. So hard up are the men, however, that the vast majority will go to work on these terms, if any openings are found for them. The ex-strikers are now looked upon as belonging to the band of unemployed.

Such a complete rout as the underground men have had is seldom sustained by workmen anywhere, and the folly of an ill-considered ill-managed strike is well illustrated by this affair on the Rand. That the absurdly high wages prevailing on the mines had to come down no one for a moment doubted, but had the men kept quiet it would have taken seven years to accomplish what the strikers by their precipitous action have done in seven weeks. The former system of underground contracting will be changed to a great extent, and the terms will be such that men will not earn from £75 to £100 per month as formerly. In the future the expert miner will be able to earn on contract from £35 to £40 per month, while the poorer class of man can earn about half that amount.

The mines are introducing the ticket system on the Rand. Before he can obtain a job the miner will be asked to show a discharge ticket from his last employer. Every other class of laborer must show a testimonial before he can get work on a mine, and in the future the miner will do the same. Seeing that they have lost the game, the miners are calling on the Government to repatriate the strikers. It would save a lot of suffering in the future were the Government to send these men to centres where labor can be found for them, for unless the

Rand expands a great deal, no openings can be found for them here.

The community and, indeed, all of South Africa were much excited last week over a bill that the Boer ministry tried to thrust down our throats, namely the 'Beer Bill,' which provided for the sale of beer, ale, etc., to Kaffirs. Since the war it has been illegal to sell intoxicating liquors to Kaffirs, and the consensus of opinion all over South Africa is undoubtedly in favor of total prohibition so far as the native races are concerned. The Boer ministry framed the bill with the idea of attracting Kaffirs to the mines, for the natives are fond (as others!) of alcoholic drinks. It was also intended to pacify the brewers of the country, for an extra tax has just been put on beer. The bill was also a concession to the Portuguese, from whose possessions on the East Coast the natives come in large numbers to the Rand. Had this bill passed, Portuguese wines would have been imported in large quantities for the natives on the Rand. So violent

will remain in the Transvaal. The rumor might be an idle one, but it comes from a very good source, and every one is hoping it is true.

Sir Percy Fitzpatrick, who for many years has been a member of the firm of H. Eckstein & Co., has resigned. He is one of the leading lights of the Progressive Party and finds it impossible to do justice to both politics and mining. He will now give his whole time to the service of the State, and his intimate knowledge of the needs of the mining industry make him an authority of great importance in the parliament at Pretoria.

Butte, Montana.

Production of Copper in August.—New Management for Barnes-King Co.—Enlarging the Belmont Shaft.—The Bullwhacker is Closed Down.—Boston & Montana.—The Machinists' Strike.—Operations Crippled.

The estimated copper output of the Butte district in August was 27,636,655 lb., against 27,157,395 lb. in July. A number of mines show an increased production, but the total was kept down by a suspension of operations at the Neversweat, Gagnon, West Colusa, and Bullwhacker, and a reduced output from the Original, Stewart, and Minnie Healey, the decrease from the two first during the latter part of the month having been due to the strike of machinists, and that from the Minnie Healey being caused by the gas from a fire in the workings of a connecting property. The total ore tonnage and copper production for August were as follows:

Company.	Tons of ore.	Pounds of copper.
Boston & Montana	104,160	7,082,880
Anaconda	125,550	7,533,000
Butte & Boston	20,150	1,229,150
Washoe	10,850	651,000
Parrot	11,625	662,652
Trenton	12,710	762,600
North Butte	38,750	3,100,000
Coalition	46,500	3,115,500
Original	27,900	1,701,900
East Butte	7,750	589,000
Pittsburgh & Montana	9,300	744,000
Miscellaneous	6,200	465,000
Total	421,445	27,636,655

At the special meeting of the stockholders of the Barnes-King Development Co., held at Kendall, a new board of directors was elected and a complete change in the management of the company made. The old directors, against whom charges of mismanagement were made by many dissatisfied stockholders, were deposed and five out of the eight new directors were elected from Butte, so that the management of the company's affairs will be directed from this city. The new directors are John Gillie, general manager of the Amalgamated mines; Charles W. Goodale, manager of the Boston & Montana mines and smelter; L. O. Evans, attorney for the Amalgamated Copper Co.; D. J. Hennessy, head of the Hennessy Mercantile Co., formerly an Amalgamated corporation; Joseph H. Case, of Butte; Thomas S. Dee, member of the Boston firm of Paine, Webber & Co.; John C. Lalor of New York, manager of the Marcus Daly estate; Julian Gerard, son-in-law of Mrs. Daly, and a New York banker. The directors elected Mr. Gillie president of the company, and selected George T. McGee, for many years one of the Amalgamated superintendents, as manager of the mines. The complete change in management was made necessary to prevent litigation with dissatisfied stockholders. The new directors announce that a complete and detailed financial report will be made to stockholders as soon as it can be prepared. William H. A. Fischer of New York, who attended the meeting and represented 125,000 shares of opposition stock, expressed

Map of the African Goldfields

was the storm of adverse criticism, however, both in this country and in England, that the Botha ministry has climbed down, and withdrawn the Beer Bill. The Boers are masters in the art of retreating, both in war and in parliament. Some devout souls consider that the grave blunder the Boers have made in bringing forward this bill is the first nail in the coffin of the ministry, but the champions of the Boers in England, the Liberal Party, have placed so many winning cards in the hands of Het Volk, that with a little skill in playing them the Dutch can hold their position indefinitely, no matter if they wreck the mining industry or not.

An interesting rumor is going the rounds just now, which, if true, will put new hope into the whole country. It is stated that the strenuous Opposition has so hammered away at the Botha ministry on the subject of unskilled labor, and the practical impossibility of replacing the Chinese at present with Kaffir labor, that the ministry has agreed to reconsider the whole question of Chinese labor, in a short session of Parliament to be held in November. If the Boers have made this concession it is the thin edge of the wedge, and there is still hope that the Chinese, save the few hundreds that have already left,

himself well satisfied with the result of the meeting and the election of the strong board of directors.

The Anaconda Copper Mining Co. has started to enlarge the Belmont shaft. The shaft is 1,000 ft. deep, but has only two compartments. It will be enlarged by the addition of another compartment and will be re-timbered. The work will take several months. The shaft will be sunk deeper after it is enlarged and will be connected at various levels with cross-cuts from the Anaconda mine. One connection from the 1,600-ft. level has already been made, connecting with the Belmont shaft at the 900. It has been said that eventually the Belmont would be made the main working shaft of the Anaconda mine, but this has been denied. That it will become an important feature in the Anaconda mine operations is certain.

Patrick Clark, principal owner in the Bullwhacker Mining Co., says the mine has been closed because of the decrease in the price of copper. "When copper dropped to 18c. the Bullwhacker ceased operations," he said. "The mine will be re-opened when improvements are completed. Investigations and experiments are now being made by C. M. Fassett of Spokane to ascertain the advisability of installing a 100-ton leaching plant at the mine.

The quality of the ore is such that it is mined for its copper value only. Copper silicates are found, but no gold or silver. The leaching process, which is likely to be installed, has been invented by Mr. Fassett. The mine has paid two dividends of \$10,000 each, and after the installation of the leaching plant, we shall be prepared to resume active operations and payment of further dividends. None of the Butte mines, the greater producers of copper, will be forced to close down unless the price of copper drops below 11c. Because the Bullwhacker has no smelter, we cannot operate and sell our product at the present prices."

The Boston & Montana Co. is sinking the East Colusa shaft, which is 900 ft. deep, the intention being to sink it to a depth of 1,200 ft. No sinking had been done on the East Colusa in 10 years, but a lot of high-grade copper ore has been mined from the property above the 900-ft. level. The Boston & Montana is increasing the size of its ore-bins at the Pennsylvania and Mountain View mines. Their capacities will be doubled in order to provide storage-room and guard against a repetition of last winter's experience when, during a short and exceptionally severe spell of weather, the ore froze and could not be shipped, necessitating a suspension of mining. The bins at the Mountain View hold 4,500 tons and those at the Pennsylvania 2,000 tons. The proposed increase will make room for 6,500 additional tons of ore.

The Gagnon, Neversweat, West Colusa, a portion of the Original, Stewart, and Minnie Healey mines are closed. The suspension at the West Colusa and in a small portion of the Minnie Healey is due to the gas from the fire in the workings of one of the properties in that vicinity, and operations in the West Colusa will probably not be resumed until the new upcast shaft is completed, when the mines can be thoroughly ventilated. The trouble at the Gagnon, Neversweat, Original, and Stewart is due to the strike of machinists. The Original mine furnished air for the Gagnon, Original, Stewart, and the Original Davis-Daly cross-cut, but the air-compressor broke and, there being no machinists to make the repairs, work had to be suspended. At no other mines of the district has the strike interfered with operations, but it will be only a question of time when other mines will have to close unless there is a settlement of the strike. So far there has been no effort made to settle by the mining companies. Ben B. Thayer, assistant to the president of the Amalgamated Co., was in Butte at the time the ma-

chinists walked out, and it is understood that he took a decided stand in opposition to granting the machinists' demands for an increase of wages from \$4.50 to \$5 per day. Other managers who have expressed themselves on the subject have declared that the demands will not be granted and that as it becomes necessary mines will be closed and kept closed indefinitely. The miners' union has put a stop to the repair work that was being done by its members, and miners can now repair nothing but their machine-drills. For several weeks they practically did all of the machinists' work about the mines.

Calumet, Michigan.

Use of Electric Power.—Winona Copper Co.—Exploration at the Globe.—The Tamarack Shafts.—The Cliff.—Shaft-houses of the Champion.

There has been a rapid increase in the use of electric power in place of steam in the Lake Superior copper mines during recent years. The Calumet & Hecla is making remarkably broad use of it and a short time ago work was started clearing the site for a large electric power-plant for the Copper Range Consolidated Co. next to the Michigan smelter, on the south shore of Portage lake. As a result of the recent visit of four directors at the Victoria mine, in Ontonagon county, it was decided to install an electric plant to light the buildings and to purchase two electric locomotives for use underground in the long drifts and cross-cuts, where it is difficult to get trammers to work. There have been numerous and important improvements at the Victoria's stamp-mill in the last few months and the plant is now treating more than 350 tons of ore daily. Eight jigs have been replaced by half that number of Wilfley tables, resulting in a greater saving of copper. The loss of copper in the tailing is now only one-sixteenth of one per cent. The new cylinder for the stamp was delivered two weeks ago, although the manufacturers agreed to have it on the ground six months ago. It is expected that the Victoria mill will be able to treat 700 tons daily after the new cylinder has been installed.

An assessment of \$1 per share, payable on September 3, will place \$100,000 in the treasury of the Winona Copper Co. for use in continuing development work. The deadlock in the copper situation has resulted in the Winona making no sales of copper since the May output was sold. As funds are needed now to provide coal and other supplies for the winter season, a call upon the stockholders was necessary, notwithstanding that the mine has been earning a fairly good profit on its limited production for the past several months.—Preparations for carrying forward the development work at the Globe property, under option to the Copper Range Consolidated, are going along steadily. A frame shaft-house for temporary use is practically completed. It will fulfill the requirements of the property during the early development period. Hoisting has been done with a bucket, but the skip will now be employed. It is expected that one of the smaller hoists formerly used at the Champion mine will be moved to the Globe.

Owing to the installation of a new drum in the engine-house at No. 3 shaft of the Tamarack, the production of that company may show a decrease for August. It was necessary to stop hoisting at the shaft for a short time while the new drum was being placed in position; the old drum had to be raised from its bearings, and the hubs taken off. Nearly 20,000 rivets were removed. The shaft, weighing 65 tons, also had to be raised. The new drum is similar to that in use at No. 5 shaft. It has a diameter of 18 ft. at its widest point and is known as a semi-conical drum. There has been no disturbance to

underground operations at No. 3. Ore was mined as usual and stacked for shipment later on.

There are now 50 men at work at the old Cliff property, in Keweenaw county, one-third of whom are employed in underground operations. The Tamarack Mining Co., which owns the Cliff, is exploring it by means of workings from the old No. 1 South Cliff shaft. A small but adequate surface plant has been provided. A siding from the Keweenaw Central railroad reaches the boiler-house and provides economical means for handling coal, etc. Grading has been finished for a railroad spur from the main line. One of the larger buildings on the property has been converted into a boarding-house and several of the other old dwellings have been repaired and rendered fit for the use of the workmen and their families.

R. M. Edwards, the superintendent, is pushing work in the Franklin's No. 1 Pewabic shaft and has pro-

Salt Lake, Utah.

New Railroad for Bingham.—Output of Copper.—Shipments From Tintic.—The Western Pacific.—Scarcity of Coal.

The filing of articles of incorporation last week of the Bingham Central Railway Co. indicates that efforts are being made toward putting an end to the ore transportation difficulties of Bingham. It is said that the new road will have an entrance into Salt Lake City and that close traffic arrangements will be made with the Harriman system. Branch lines are to be built to the various points where ore goes for reduction in mill and smelter, and thus the Bingham Central is to become an active competitor of the Rio Grande Western—both for freight and passenger traffic. The camp of Bingham will be entered in a unique way. The Mascott Tunnel of the Dalton & Lark mine is to be utilized for this purpose; it

The Copper Region of Lake Superior.

Each rectangle is a township, six miles square.

gressed as far as the 14th level. It has been costly work re-opening this shaft, as the workings were abandoned several years ago and fell into a bad state of decay, necessitating the shaft being practically rebuilt at many points.

Rapid progress is being made by the Wisconsin Bridge & Iron Co., which has the contract for enlarging the shaft-houses at the Champion mine. Work at E shaft has been completed and attention is now being confined to B shaft. As soon as the latter is finished, work will begin at C and D shafts. At B shaft-work is well under way on the new hoist.—Thomas F. Cole, Chester A. Congdon, C. D'Autremont of Duluth, and John D. Ryan of Butte, were visitors here this week. Some of them visited the Keweenaw Copper Co.'s workings in company with Capt. Thomas Hoatson of Calumet, mining director for that corporation.—Edward Kopps, superintendent of the Michigan gold mine, near Ishpeming, has been advised by the Abbé Engineering Co. of New York that the tubemill ordered several months ago, has been shipped.

Two diamond-drills have been working for a month on the Copper Range company's property, at No. 1 camp, northwest of the Champion mine, near the road from Painesdale to Trimountain. Important results are expected from the work, and progress has been watched with a good deal of interest. Up to the present no information has been given out as to what has been accomplished, and probably will not be for some time. The fact that the crew is kept at work is considered a favorable indication that some trace of copper has been found.

is now being extended into the domains of the Ohio Copper Co. and by continuing it, the ores of the Utah Copper, Boston Consolidated, and other mines of the district will be made accessible. Although the articles of incorporation do not indicate it, it is nevertheless true that F. Augustus Heinze is a factor in the enterprise. It is proposed to build about 50 miles of track.

Figures obtained from authentic sources place the copper output of Utah smelters during August at 8,000,000 lb., which is considerably under the production of July. The decrease is due to the transportation difficulties—principally at Bingham. The Boston Consolidated laid off 300 men because of the lack of cars; while the Yampa, Utah Copper, and Utah Consolidated, for the same reason, could not keep their production up to normal. The lead production for the month is estimated at between 13,000,000 and 14,000,000 pounds.

The shipments of ore from the Tintic district during the past week aggregated 176 carloads, the contributing mines and respective amounts being: Beck Tunnel, 11; Colorado, 10; Eureka Hill, 9; Yankee Con., 4; Uncle Sam Con., 7; May Day, 7; Eagle & Blue Bell, 7; Centennial Eureka, 51; Bullion Beck, 4; Ridge & Valley, 3; Seranton, 8; Victoria, 2; Ajax, 3; Grand Central, 8; Lower Mammoth, 7; Mammoth, 20; Carisa, 1; Depue, 5; Victor Con., 1; United Sunbeam, 1 carload.

The New England Gold & Copper Co., controlled by Boston parties, produced 15 cars crude ore and concentrate during August. This brought returns of \$500 per car at the smelter.—The Utah Apex Mining Co. made a good record of production in August. The Markham

Gulch mill was kept running up to capacity on low-grade ore from this property.—The Utah Consolidated Mining & Milling Co. recently organized, has begun the development of its Tintic property, which was a producer of some consequence several years ago.—The Lower Mammoth mine at Tintic has been closed pending the installation of a new hoisting equipment. An electric plant is being installed capable of going to 3,000 ft. with the shaft.—The new equipment recently ordered for the Sioux Consolidated is in operation.

Official announcement has been made that the Western Pacific Railroad Co. will open its line for freight and passenger traffic between Salt Lake and a junction point with the Nevada Northern Railroad in Nevada on October 1. The road being a Gould enterprise, it will be operated in connection with the Rio Grande Western at Salt Lake. The Western Pacific will be the shortest route from Salt Lake to Ely by about 100 miles.—The fuel famine experienced in Utah last winter, and the probability of another one during the coming winter, has resulted in the organization of several new coal mining enterprises. There are 14 coal mines in operation in the State at the present time, and the estimated output is between 6,000 and 7,000 tons per day. In Carbon, Emery, and Iron counties are vast undeveloped deposits that will soon be made available and put an end to the present scarcity of coal. Domestic coal is selling at from \$1.25 to \$1.75 per ton higher in Salt Lake than it did this time a year ago. Retailers get from \$6 to \$6.50 per ton.

Cripple Creek, Colorado.

Lease on the Abe Lincoln.—New Orebody in the Cresson.—Portland Continues Deep Development.—Golden Cycle Mill.—Elkton Pays a Dividend.—The Vindicator Mill.

John Sharpe, the successful general manager of the Colorado State Investment Co., has acquired possession of the lease held by the Tunnel Mining & Leasing Co. on the Abe Lincoln property of the Stratton estate, the cash consideration being \$5,000. This property has been under the management of Walter Swanson, who has placed it in the first rank of producers. It was supposed at one time to have been worked out after making several small fortunes for various lessees, but under Mr. Swanson's management it has come to be one of the best mines in the district. Mr. Sharpe has started with a full force of men and it appears probable that the first six cars from a clean-up of ore already broken in the stopes will compensate for the price paid for the lease. Operations that have brought the property up to its present high state of development were begun on a vein less than 5 ft. wide, the vein steadily increased in size until it now measures from 12 to 15 ft. across, and has produced ore to the value of better than \$30 per ton for four months. Mr. Swanson goes to Wyoming to take charge of holdings recently acquired by his company near Shoshone.

The Cresson property, which has been one of the steady producers of the camp, has opened a new ore-shoot on the 500-ft. level. This was accomplished by driving a cross-cut north of the shaft. The property has made an output of about 2,000 tons per month, and this new find is certain to increase the tonnage. Chicago capitalists control the company and announcement is made that at a meeting to be held in this city on September 3 the capital stock will be increased from 1,000,000 to 1,250,000 shares, of \$1, and the number of directors from 5 to 9 members, these propositions to be submitted to the stockholders. The object of increasing the capital stock is for the purpose of acquiring the lease held by the Bull

Hill Mining & Developing Co., whose output has been about 2,000 tons of ore per month.

The Portland continues the work of development at a depth of nearly 1,600 ft. from the surface. One of the orebodies from the 1,200-ft. level is about 20 ft. wide and its length is not yet determined; other orebodies not so wide at this depth are giving profitable returns. Sinking will continue some 40 ft. more when cross-cuts will be run to connect with the 1,200-ft. level. The Portland mill is operating at nearly full capacity on ore entirely from this mine.—A statement has been made that the Golden Cycle mill will be in operation early in December; the work of rebuilding is being carried forward rapidly and the management announces its willingness to accept contracts at the old rates.—The Jennie Sample property has drawn the fire from the boilers and will not do any more hoisting until the Golden Cycle mill resumes operations. It is unwilling to accept the smelter rates and, though there is a large amount of ore broken in the stopes, prefers to wait. Some useful development work has recently been accomplished; large orebodies are blocked out on both the 300 and 500-ft. levels and a cross-cut has been driven to make better air-connections.

The Elkton Consolidated Mining Co. has declared another dividend, the fourth this year, the sum disbursed amounting to \$37,500. The condition of the mine is excellent. Cross-cutting is under way on the 700 and 800-ft. levels; the shipping ore is hoisted from the 600 up to and including the 300-ft. levels. Ore that would be considered of good average value in other properties is held in reserve, only the higher grade is hoisted. The smelter returns amount to about \$35,000 per month on an output of 1,200 tons.—The Christmas Gold Mining Co. has declared a dividend of \$1,000.—The Proper claim of the Stratton estate on Gold hill has made a second shipment from a recent strike, and the interest of prospectors is aroused so that many efforts have been made to obtain leases on adjoining properties. The mine is under lease to the Union Leasing Co. Some excellent specimens of sylvanite are on exhibition. The vein is now 2 ft. wide, and the orebody was encountered while driving for the junction with another rich orebody.

The experimental mill on the Vindicator property recently renewed operations and is handling about 40 tons of ore per day. The management expects, however, to increase the capacity in the near future.—A new cyanide mill is in contemplation on the Wedge property on Raven hill, specifications and surveys have been made. Eastern capitalists are looking over the property and until they finish their inspection nothing will be done toward the erection of the mill; if negotiations fall through, the construction of the mill is likely to be started. The Wedge has been idle for some time owing to a disagreement, but a large amount of ore lies broken in the stopes and about \$75,000 worth is estimated to be in sight in two big ore-shoots opened from the 300-ft. level.—After a shut-down of a short period the Jo Dandy mill has resumed. A new Butters filter-press has been added. The mill treats 100 tons per day.

A strike has been made on the Red Bird property belonging to the National Mining Co. on Gold hill. Harris & Co., operating the lease, have been doing development work for several months, following a vein for 50 ft. without getting pay-ore. Sinking was finally decided upon and 20 ft. below the tunnel-level rich sylvanite was encountered in a breccia formation. The vein measures at this point 4 ft. between walls and the winze put down is but 200 ft. from the portal of the tunnel.—The Trilby mine had a contract with the Golden Cycle mill to treat its ores, but is compelled to make other arrangements since the destruction of that plant.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

ANORTHOSITE is a name applied to granitoid rocks that consist of little else than labradorite, and that are of great extent in eastern Canada and the Adirondacks. These rocks are extremes of the gabbro group, into whose typical members they shade by insensible gradations.

A **SYSTEM** of riffles, consisting of a row of blocks alternating with an equal area of rocks, has been found to work successfully. This arrangement in the sluices reduces the wear on the blocks, but it is not desirable for those sluices that have to be cleaned up frequently.

THE object of annealing structural steel is to secure homogeneity of structure that is supposed to be impaired by unequal heating or by the manipulation attendant on certain processes. The objects to be annealed should be heated throughout to a uniform temperature and uniformly cooled.

THE majority of the important limestones are of marine origin, but in certain geological formations fresh water ones are well developed. The calcareous remains of organisms have been their principal source, and of these the foraminifera, the corals, and the molluscs, are the chief contributors.

METASOMATIC is a term used to describe the replacement of one or more of the minerals of a rock by others. The form of the originals is not at all preserved as in pseudomorphs, nor does the chemical composition remain the same while the form alters as in paramorphs, but both customarily change.

LIMESTONES feel the effect of metamorphism with exceptional readiness, and under deforming stresses, probably accompanied by elevation of temperature, and in the presence of water, or along the contacts with intruded dikes and sheets of igneous rocks, they lose their sedimentary characteristics, such as bedding-planes and fossils, and change into crystalline marbles.

FRAMED STRUCTURES in general consist of one or more triangles, for the reason that the triangle is the one polygonal form whose shape cannot be changed without distorting one of its sides. Problems in stresses of simple framed structures may generally be solved either by the application of the triangle, parallelogram, or polygon of forces, by the principle of the lever, or by the method of moments.

CONDUCTION is the transfer of heat between two bodies, while convection, or carrying of heat, means the transfer and diffusion of the heat in a fluid mass by means of the motion of the particles of that mass. The conduction of heat through a stagnant mass of fluid is slow in liquids, and almost unappreciable in gases. It is only by the continual circulation and mixture of the particles of the fluid that uniformity of temperature can be maintained in the fluid mass, or heat transferred between the fluid and a solid body.

RECTIPROCATING steam engines have been broadly classed either as 'high-speed' or 'low-speed' engines, but these terms are misleading, as the piston speed, which is the determining factor in any engine, is the same in both. In addition to this, in the low-speed

engines there are larger and heavier masses of metal in motion. The terms 'quick-revolving' and 'slow-revolving' have recently been substituted, and more accurately express the relation between the two types. The so-called high-speed engine runs at 300 to 400 rev. per min., and the low-speed from 50 to 150 rev. per minute.

DRY-WASHING was carried on in the early days principally by Mexicans, in those districts where water could not be obtained. Their method consisted in pulverizing rich dirt, thoroughly drying it, and then working it in a batea, the earthy portions being separated from the gold by a circular motion. The gold was also extracted by winnowing. Recently a variety of machines have been invented for this kind of work, but the application has necessarily been limited. Several novel applications of these principles in the arid deserts of the Southwest have proved successful in a limited way, notably in Nevada and Arizona.

TEMPERING STEEL is the act of giving it, after it has been shaped, the hardness necessary for the work it has to do. This is done by first hardening the piece, generally a good deal harder than is necessary, and then toughening it by slow heating and gradual softening until it is just right for the work. A piece of steel properly tempered should always be finer in grain than the bar from which it is made. If it is necessary, in order to get the required hardness, to heat it so that after being hardened the grain will be as coarse as, or coarser than, the grain in the original bar, then the steel itself is too low in carbon for the desired work.

BAUXITE has proved to be of great value as a basic refractory material in that it resists well the scouring action of metallic oxides in the furnace. For this purpose it is used most conveniently in the form of bricks. The Berger patent covers a process for making these bricks. Natural high-alumina low-silica bauxite from Arkansas is used, bonded by a small percentage of plastic fire clay, sodium silicate, or lime. The bricks contain from 88 to 90% of alumina and from 10 to 12% of ferric oxide, silica, and titanio acid. The percentage of silica can be reduced to 6 or 8% by the use of a bond free from silica, so that the brick is not appreciably detrimental to basicity. Bauxite brick seems to be especially adapted for the linings of basic open-hearth steel furnaces. The highest grade is used in the floor and walls up to the slag line, protected by a bed of calcined bauxite. Above the slag line cheaper brick with a lower percentage of bauxite can be used.

THE rigid classification of materials into conductors and non-conductors is responsible for a prevalent idea that the former only are capable of electrical conduction. Strictly speaking all materials are conductors in the sense that they are to some extent able to transmit electricity. Current is transmitted through gases by means of electrically charged particles, and modern theories substantially agree that the conducting process is the same for all substances whether they are in a gaseous, liquid, or solid state. These charged particles which have been termed ions are assumed to consist of atoms or of combinations of atoms or of infinitely smaller negatively charged particles known as electrons. It is conceived that all atoms contain one or more detachable electrons whose aggregate negative charges are balanced by an equivalent positive charge possessed by each atom, and the addition of an electron, or its removal from one of these neutral atoms or combinations of atoms forms an ion possessing an excessive positive or negative charge.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A Fundamental Problem.

The Editor:

Sir—What is the matter with 'S.T.'? He is seriously in error in his otherwise interesting communication in your issue of August 17 when he tells would-be investors to keep away from mining. That is what it amounts to when he says: "The mining districts, and every conceivable spot, to the ends of the world, are constantly being scoured by an army of keen-eyed, clear-brained, carefully trained men." "Whose business it is to go over the surface of the earth with a fine-toothed comb, from the poles to the equator and back." Again, "Always hunting for desirable properties, promising prospects, or good indications." He means by this that every new find that is good for anything is snapped up the moment the strike is made. Mining engineers are everywhere either out for themselves or in the employ of syndicates, and when they see the prospector hurl his pick through the air and know that his dream has at last come true, they spring to him from behind every greasewood bush and boulder, and fill in their already signed checks when he names his price.

Experts play their part and are entitled to all they get, but even they would smile over this fine-toothed comb-work between the poles and the equator. Rarely do any of them get onto the ground until the merits of a discovery of mineral is an old story in the camp where it was made; and a mining engineer is not a fixture in one mining district out of fifty, and as to his getting around to other than bonanza camps, it can be said that his visits to where the sizzle of a boom is not heard, are like those of the angels, few and far between.

A mining district that cannot show to those who would embark in this the most profitable of the industries an opportunity for sound investment, cannot justly be considered as being within the mineral belt, and is a place the wise will avoid.

NORTH STAR.

Atolia, Cal., August 19.

Ore Deposition.

The Editor:

Sir—I have been reading paper after paper on ore deposition, including the splendid one in your issue of August 17. My old master, Bernhard von Cotta, taught me, both in the classroom and in the field, that we must take everything into account before forming opinions or drawing conclusions. Now we know that rock masses contain enormous quantities of hydrogen gas, and so do mineralized bodies. In vain have I sought for even the word hydrogen in all these treatises, and yet it seems to me that to the chemical geologist (and every geologist should be well grounded in chemistry), the action of hydrogen cannot be neglected, especially if nascent and under pressure in vast quantities. How did it get there, and what has it done, and what can it do, are questions that confront us, and so far I have seen no attempt to tackle the problem.

We hear a great deal about carbonic acid and the part it plays, but most acid rocks, as far as I know, contain from two to fifteen times more hydrogen than carbonic acid gas. The basic rocks, such as basalt, seem to have about equal quantities of hydrogen and carbonic acid.

It seems to me that as a reducing agent it may be one of the main causes in the formation of native metals and lower sulphides such as pyrrhotite and bornite, which

are often associated with gold in acid rocks very high in hydrogen. I remember hearing Henri St. Claire Deville say that he thought hydrogen nascent and under high pressures, and from high temperatures to low ones, must have exercised an immense influence on the formation of rocks and mineral deposits. At that time he was studying the dissociation of gases at high temperatures. I suppose what we have stored up in the rocks in the way of gases is merely the remnant of nature's prodigality, but to read some papers on ore deposition you would think nature was as mean as man. The hydrogen in the rocks plays a great part in disintegration as exemplified in granites, which run very high in hydrogen, and it also must influence plant life. If the hydrogen be derived from water, think of the nascent oxygen set free below, and the work it must have done in mineral zones and is still doing. Modern research is showing us the great influence of even rare gases and emanations, and it seems to me that we shall have to change our ponderous theories on ore deposition for something lighter and more up-to-date. The trail of water is plain and easy to follow, but not so with gases. We see the camel, but miss the gnat. Forty odd years' experience, in the field and underground, have led me to believe M. Deville was right, and that gases have played a greater part in the chemistry of the earth than solutions; and now modern research is pointing the same way. No modern analysis of rocks or minerals is complete that does not give the gases as well as the solids. The enormous quantity of hydrogen in the earth's crust must be there for a purpose; it must have done and be doing something. The longer I live and travel, and the harder I work, the less I know.

WALTER E. KOCH.

El Paso, August 23.

Testing Mill-Tailing.

The Editor:

Sir—Assayers at gold mines are often called upon to determine the cause for high losses in the tailing. The amalgamator in charge of the mill is positive that the assayer has got the samples or fluxes in the assay-office salted; or else is reporting the tailing high out of pure cussedness. At such times it becomes necessary to make a careful and systematic investigation of the milling processes.

The conditions governing good amalgamation and concentration are now so generally understood that excessive losses are of rare occurrence. A casual inspection of the plates and a vanning test on an average sample of tailing should be sufficient to detect any serious errors in the treatment. If the amalgam is hard and crystalline, or is breaking away from the plates in little crooked strings, with puddles of mercury dripping from the lower ends of the plates; or if the concentrators are dirty and sloppy, I would advise a change in the mill-crew before spending much time in trying to ascertain the cause of loss.

If, however, everything in the mill seems to be properly conducted, the trouble will generally be found in the milling process itself as being not properly adapted to the ore. At such times, if there are reserves of ore in the mine large enough to justify an installation, it is best to make a series of cyanide tests on the ore and tailing, as this process is likely to be effective in the majority of cases. Where this fails, as it sometimes does chiefly from chemical causes, it is necessary to improve the amalgamation and concentration processes to effect the highest recovery. In my experience I have found that the most fruitful source of avoidable loss is occasioned by a too fine crushing of the ore, as indicated by an excessive loss in the fine slime.

To begin with, for a laboratory test, it is essential first

to procure an average sample of the tailing. This is best taken by means of some automatic device that takes a regular and true sample at short intervals, for a considerable period of time.

An amalgamation test is sometimes desirable, though I have usually found it unreliable, for the reason that if there are mistakes in the amalgamating of the ore, it is very difficult to recover floured amalgam by the ordinary laboratory amalgamation test of agitating the tailing in a bottle with mercury. Where the amalgam has become hard and crystalline it will not be readily taken up by mercury; though sometimes if the tailing is heated during drying, the amalgam undergoes a physical change that renders it amalgamable in a bottle. I once found a case of this kind at a mine in Shasta county where I had an engagement to investigate the mill-losses. The men in charge were running the mill with a deep discharge, and trying to catch most of the gold on inside plates, which were in a very hard condition, and by their smooth surface, clearly indicated a scouring action. An amalgamation test on a settled sample of the tailing failed to show any appreciable recovery. But when I heated a sample to the boiling temperature before making the test, I was able to recover about \$1.50 per ton by amalgamation. On the other hand, if the loss is occasioned by base mineral or by over-milling the ore, the floured particles are usually coated with a film that interferes with the test.

For making a test I get as fair a sample as I can from the mill, consisting of approximately two pounds of the wet tailing. The sample should be taken and given sufficient time to settle clear without the use of any precipitants such as alum or lime water. Any coagulating substance will interfere with the subsequent separation of the slime into different grades of settling.

For the amalgamation test I charged the wet tailing into a large acid bottle, add about 100 grains of pure mercury, and agitate for about one hour. I often had a great deal of trouble in procuring quicksilver that was entirely free from gold until I hit upon the following scheme for preparing it: I take an excess of the impure retorted mercury and dissolve a portion of it in strong nitric acid. If there is more of the mercury than the acid can dissolve, all of the gold contents will remain amalgamated in the undissolved portion. I decant the nitric solution and precipitate with pure copper wire, using for the purpose any old scraps of electric wire. While the mercury prepared in this way may not be chemically pure, I have never detected a trace of gold in any of it, even when prepared from mercury that was heavily charged with the metal. Having given the charge of tailing sufficient agitation to amalgamate all of the gold that will amalgamate in this way, I wash out the charge into a clean mining pan; and using some other clean receptacle for a tank, I carefully ran out and separate all of the mercury and concentrate. To effect as close a concentration as is possible on a well-adjusted vanner, it is necessary to repeat the vanning several times. Having separated the amalgam and concentrate from the tailing, I next separate the quicksilver from the concentrate. Quite a lot of the mercury will usually be found so badly floured that it is difficult to get it to unite together in one globule. To effect this, I take a little piece of pure test silver and rub the floured mercury; it will amalgamate onto the silver and can be rubbed off with the fingers, and added to the other. After collecting all of the mercury, I dissolve both the mercury and silver in nitric acid, and collect the gold on a filter for future fire-assay.

I next sieve the tailing under water on a 100-mesh sieve; finally washing them with a little clear water

which I add to the slime. I then dilute the slime up to about the original volume and allow it to rest for a period of five minutes, to settle out the heavy fine silicates, and decant the slime into another larger and clean receptacle. This operation I repeat about three times, using additions of clear water for the purpose of floating all of the fine suspended slime. The different products can now be dried, weighed, and assayed. It is usually advisable to still further separate the coarse sand that was retained on the 100-mesh sieve into several grades by means of a series of coarser sieves before assaying them; weighing out and estimating the exact percentage of each different grade of material of which the sample was composed. The total weight will give a basis for estimating the percentage and value per ton of concentrate, and the recovery per ton in free gold. The product passing a 100-sieve and settling in five minutes contains mineral that should mostly be concentratable on a canvas plant; it can be re-cleaned on properly adjusted vanners and brought up to a fair grade. The slime remaining in suspension for five minutes will yield considerable of its gold also on a canvas plant, if given a careful sizing to eliminate all heavy particles of the gangue material before treatment. But this slime is generally too fine to withstand the force of the wash-water on vanners and cannot be successfully re-cleaned; in some instances it will build up by adhesion on canvas to a high-grade product sufficiently rich for treatment; though the best scheme that I have ever found was to collect this fine mineral on submerged surfaces.

Now to return to the milling problem: If the coarse silicates are high, they evidently require finer crushing, but if the slime is the highest product it would indicate either hard amalgamation, base mineral in the ore that fouls the amalgam and renders it brittle, or that the ore is being over-milled. In case of the last the tailing will be lowered by using a coarser screen and lower discharge, with outside amalgamation.

If both the coarse particles and the slime are high, the ore should be twice crushed, followed in both instances by amalgamation and concentration with the additional adjunct of an up-to-date canvas and slime concentrating plant.

WILTON E. DARROW.

Sutter Creek, California, August 27.

An Engineer's Guarantee.

The Editor:

Sir—I read with much interest your editorial in the issue of August 24 on the Zinc Corporation, and I quite appreciate your compliment to Mr. H. C. Hoover, who evidently faced the music like a man. It is true that a responsible engineer never guarantees the percentage of extraction, or the tonnage in sight in a mine, or other things that are in the nature of estimates, but surely it is not quite correct to say that he "never guarantees anything," for engineering consists largely in the accurate ascertaining of physical facts, and as to them he is expected to be held responsible. The depth of a shaft, the width of a vein, the assay of a particular ore, the cost of a machine, and such matters are outside anything in the nature of a guess or an estimate; an engineer is expected, and usually expects, to be held responsible for statements concerning them. While most of us will endorse the position of Mr. Hoover in refusing to guarantee the success of a metallurgical process, and approve of his courage before a meeting of shareholders, I think it right to demur to the sweeping statement that a responsible engineer never guarantees "anything."

Oakland, August 29.

Hydraulic Mining in Cariboo.

Written for the MINING AND SCIENTIFIC PRESS
By DOUGLAS WATERMAN.

The Cariboo district, in British Columbia, has been known for its gold since the days of the Fraser river excitement. The early miners found their way into the rich diggings over the old trail, portions of which may still be seen by the traveler on the Canadian-Pacific, which skirts the opposite bank of the Fraser river canyon. The river bars and flats were worked with rocker and sluice-box, and by means of wing-dams the rich bedrock of the streams was exposed. Spring freshets have long since wiped out all traces of these wing-dams, which exhibited the ingenuity and resourcefulness of the pioneers, and it has been found that they did their work in a thorough and systematic manner.

Some years ago a company was formed to work the

from the old mining camp of Quesnelle Forks and about the same distance from the outlet of the great Quesnelle lake, about 190 miles by way of the 150-mile House, and about 170 miles by way of the 108-mile House and Horsefly from Ashcroft (on the line of the Canadian-Pacific railway). The journey is made at an easy grade over excellent roads, which, as far as the 150-mile House, are under Government supervision. The shorter route is used in winter, when most of the heavy freighting is done. On approaching the scene of mining operations the observer cannot fail to be impressed by the magnitude and extent of the ancient river-channels marked by valleys and a chain of lakes, and by the terrace gravel exposed along the road for miles. The mining leases of this company cover the auriferous deposits of this river system for a distance of 10 miles. The channel now being exploited parallels the south fork of the Quesnelle for two miles, from where it is first exposed by Drop

Gorge of the Quesnelle River.

bed of the Quesnelle river and a large sum of money was expended in the construction of a masonry dam at its head. When the gates were finally closed and the work of excavation begun, these old wing-dams were disclosed and it was found that the river for several miles had been completely stripped of its riches. With the passing of the white miner, the country was given over to the more frugal Chinese, who occupied the deserted cabins and with their rockers sought the best spots in the shifting sands of the river bars. It is noteworthy that the first hydraulic work done in the country was by a Chinese company, which uncovered the ancient channel now being worked by the Consolidated Cariboo Hydraulic Mining Co., Ltd., and recovered gold valued at \$900,000. This property, after passing into the hands of the latter company, produced for a period of ten years, from 1894 to 1904, \$2,457,669, an average yield of 9.9 cents per cu. yd. The Consolidated Cariboo mine is situated at Bullion on the south side of the south fork of Quesnelle river, four miles

gulch to the point where it finally breaks through the narrow ridge that separates it from the present river. The excavation begun by the Chinese company years ago has been advanced over 2,500 ft., exposing a deposit of auriferous gravel 600 ft. wide at the top, 300 ft. at the bottom, and 400 ft. deep. The face of the excavation shows 75 ft. of top gravel, under which lies 100 ft. of volcanic mud, the remainder being designated as bottom gravel. Owing to the indurated nature of the deposit, the face presents a nearly perpendicular wall which is attacked by undercutting. To protect the men and monitors from the dangerous caving of the ground occasioned by this method, the face is advanced in two sections, leaving a narrow strip of gravel between. The monitors are placed directly in front and close up to this 'toe,' which has the effect of deflecting the frequent caves which would otherwise prove most destructive. The bedrock of the channel is of sufficient elevation above the present river to allow of a bedrock sluice 1,200 ft. long

and a drop at the dump of 50 ft., which has proved sufficient, owing to the torrential nature of the stream, which carries away the tailing as rapidly as deposited. For the future working of the mine, a sluice tunnel 1,200 ft. long is required. At the time of the writer's visit in 1905 such a tunnel, 10 by 10 ft. in the clear, large enough to accommodate a sluice 7 ft. wide by 3 ft. deep, and a walk two and a half feet wide on one side for the sluice-tender, was under construction and had already been advanced 800 ft. No. 15 Gardner electric drills were employed in the work and had proved highly efficient. The distance driven per week was as much as 38 ft. in hard rock; the average cost during the season was \$12 per foot, a remarkably low figure. Power for the drills is obtained from one direct-current dynamo built by the General Electric Co., rated at 30 kw., full-load current 240 amperes at 125 volts, which also furnishes light to

includes two pooling reservoirs situated near the mine at the delivery end of the two main canals. They are utilized to collect the early spring water and to conserve the water contained in the canals after the head-gates are closed. Some idea of the cost of ditch construction in this district may be derived from the Morehead ditch, a canal 10 miles long with a capacity of 2,500 miner's inches of water, in which the average cost of excavation was 65c. per cu. yd., rock-work being figured at \$1 per yard. The cost of flumes was \$18,000 per mile and the average cost of canal per mile, including flumes and waste-gates, was \$8,000.

The present water supply has proved inadequate for the economical working of the mine, and there is under construction a canal and pipe line to tap the waters of Spanish lake, which will insure an abundant supply throughout the working season of seven months. It may be of

Cariboo Hydraulic Mine.

This photograph and the one on the opposite page should be contiguous as they represent a single view, the ridge between the river and the mine is shown to the left of this illustration and to the right of the one preceding.

the mine and camp. By the use of electricity instead of oil for lighting a saving of 70% is effected.

The method of working in two sections necessitates two lines of sluices, which are 7 ft. wide by 1 ft. deep, paved in part with ordinary wood blocks one foot thick, and by improved longitudinal steel riffles. Sluices are not curved at the turns or at the cut-in, but a drop-off of from 4 to 6 in. is provided, which accelerates the material sufficiently to prevent the clogging of the sluice. The sides exposed to the impact of the boulders are protected by end-blocks laid flush. The grade of sluices is nine, eight, and seven inches. The water is obtained from three lakes, with a storage capacity of 1,016 million cu. ft., through 33 miles of well-constructed canals capable of delivering 5,000 miner's inches under 420 ft. head. The average duty of a miner's inch of water is 4.9 cu. yd. of gravel removed per 24 hours. The water-sheds drained by the lakes and canals aggregate 59.4 square miles. The system also

interest to note the relative efficiency of different classes of labor employed in ditch construction:

Chinese	4 cu. yd. at \$1.75 per day	\$3.75c per cu. yd.

A telephone system 35 miles long places the office and store in communication with reservoir and canal tenders, foreman of the hydraulic pit, sawmill, and blacksmith shop. This was installed at a cost of \$100 per mile with an annual expense for maintenance of about \$100. The wide and level spoil-bank of the ditches is planted with clover and timothy from which a crop of hay is harvested each season, providing winter feed for the company's live-stock. But the chief benefit derived from planting this kind of fodder lies in the fact that it effectually prevents the growth of willows, the roots of which are a constant menace to the ditch. From the pent-stock pro-

vided with the usual screen and sand-box, the water is taken through two lines of 30-in. riveted steel pipe to No. 8 hydraulic giants, with deflecting nozzles of 7 and 9 in. diameter. Throughout the steep descent into the pit the pipe-lines are laid on ladders and are secured by lugs riveted to the under side of each length of pipe and by wooden yokes bolted to the timbers, and are securely anchored and braced at the turns. With the exception of the foreman, shift-bosses, and pipe-men, Japanese labor is employed in the pit, and a large crew is required to break up the boulders and huge pieces of cemented volcanic

Cross Section of Alluvial Deposit at Cariboo.

mud, which work is done with sledges and by 'bulldozing.' The men work close to the overhanging face of the cliff, from which large masses are constantly falling, but one of their number is detailed as a look-out, and so expert has he become in judging the face of gravel, that ample time is given the men in which to seek the protection of the 'toe' referred to, and but few accidents occur. The Japanese are expert powder men. They handle the dynamite from the thawing-house through the fuse-cutting and priming-house and place and fire the charges. The cost, in explosives and labor, of disintegrating the indurated volcanic mud forms a large proportion of the operating expenses of the mine. Bank blasting has been tried with pronounced success and will probably be employed in the future. A shaft was sunk to a depth of 150 ft., about 50 ft. below the stratum of indurated volcanic mud and at a distance of about 400 ft. from the face and midway between the rims. A drift was run to the face for drainage and ventilation and then powder drifts were driven to the east and then to the west rims from the main gangway. These were charged with 4,540 kegs (113,500 lb.) of black blasting powder, and after tamping, fired by electricity. It was estimated that 3,872,000 cu. yd. of clay and gravel were disintegrated and made available for economical washing at a cost of 0.66c. per cu. yd. Besides the hydraulic plant, there are the necessary adjuncts to a fully-equipped mine of this size. There is a steam-power saw-mill with a capacity of 4,000 ft. of lumber per day, fitted with planing, matching, boring, and framing machines, a band-saw, emery wheel, and grindstones, a separate camp for the Japanese laborers and accommodations for the mechanics and shift bosses, with separate house for the foreman. A model kitchen and dining room with guest chambers in the second story occupy one building; a hospital, general office, assay-office, and draughting room, melting and retort room, manager's residence, a well-equipped store and butcher shop, together with barns, stable, carriage house, blacksmith house, etc., form quite a village. The company raises its own cattle, sheep, and poultry, while a farm and garden supply the camp with vegetables and small fruits.

The Electric Age.

Just as the nineteenth century was the Age of Steel, the twentieth century, in its beginning at least, is the Age of Electricity, and electricity demands copper in ever increasing quantities. For the last six decades of the nineteenth century, says 'The Copper Handbook,' by Horace J. Stevens, the production of the leading metals increased at the rate of almost exactly $6\frac{1}{2}\%$, compounded yearly, but in the last decade of the century, copper left the other metals behind, and for 15 years past the average ratio of increase in copper production has been 8%, compounded yearly. This difference of only $1\frac{1}{2}\%$ in the ratio of yearly increase may seem small, but, like the fable of the horse's shoes, for which the first nail brought a penny and each nail thereafter was doubled in price, the cumulative results are surprising and at the end of 15 years have run into hundreds of millions of dollars. In 1881, a quarter-century past, the world's production of copper was 163,000 long tons, worth an average of 18c. per lb., giving a total value of \$65,000,000, in round figures, while at the present moment the copper mines of the world are producing at the rate of nearly 800,000 tons per annum, worth, with copper at a little more than 20c. per lb., \$1,000,000 for every day in the year, or at the rate of \$365,000,000 for 1906—an increase of almost five-fold in the world's copper bill, in a quarter of a century. With electricity finding new uses daily and with a rapid extension of electric energy for power, traction, and many other

Longitudinal Steel Riffles in Sluice-Boxes.

employments, there is small hope that the poor old world will be able to curtail its copper bill to any important extent, and every reason to believe that the world's copper, 10 years hence, will cost considerably more than the world's iron and steel cost 10 years ago.

DURING 1906 Bilboa exported 12,944 tons of pig iron to foreign countries and 20,277 tons to other parts of Spain—a total of 33,221 tons, compared with 67,678 tons shipped in 1905.

Metallic Sulphides in the Tuffs of Santo Domingo.

Written for the MINING AND SCIENTIFIC PRESS
By F. LYNWOOD GARRISON.

The copper deposits of the San Christobal district, in Santo Domingo, are found on the southeastern edge of the great mountain complex that constitutes the core or interior of this island, about 25 miles northwest from the city of Santo Domingo. I was impressed by their unusual and peculiar character when I first visited them in the winter of 1905, although at that time they were in an undeveloped condition. Finding some copper ore at the contact of an eruptive rock and the Cretaceous limestone, I naturally expected to see the usual accompanying contact phenomena. In this I was not altogether disappointed, as the limestone was found to be somewhat crystallized or marbleized near the contact. The copper minerals thus far have been found only in the eruptive. The best ore of the district is wholly in veins and pockets in the basic crystalline rocks first assumed to be dioritic, but since determined microscopically to be tuffs of an indefinite mineralogical character. This fact might explain, at least in part, the relatively slight degree of contact metamorphism exhibited in the aforesaid Cretaceous limestone. The copper minerals in the tuffs near the limestone contact are chiefly chalcocite associated with a preponderating proportion of limonite, some malachite and brochantite (a copper sulphate). As yet not the slightest trace of copper has been observed in the limestone, though a more careful and systematic search may be more successful.

In order better to understand the topic of this paper, it will be well to glance at the outline geology of Santo Domingo in particular, and the West Indies in general.

The genetic relations between the Greater Antilles and Central and South America appears to have been noticed first by Suess¹ and Von Seebach, who drew a parallel between the orographic structure of the European Mediterranean and American Caribbean basins, and demonstrated how the features that are dominant in one are representative in the other. Areas of long existing weakness in the earth's crust are recognizable in both regions, and the progressive disruption that took place over long geological periods still continues. Continental masses have been broken sectionally into these areas, and their fragments lie in part scattered about as islands of archipelagic seas; mountain chains have been sundered, disrupted, and drowned in the resulting oceanic troughs, though some of their higher pinnacles rise as islets from the abysmal depths.² Suess has shown in a masterly manner that where these great continental breakages take place they are associated with seismic or volcanic disturbances. The connection between the Antillean disturbances of the Miocene on the east-west trends and faulting in southern Mexico has been observed by Hill; the great active volcanoes of this part of Mexico being supposed to be due to weak spots or fissures caused by the crossing of the Cordilleran and Antillean trends.³ According to Heilprin⁴: "The boundaries of the region of weakness that is included within or touched by the Caribbean-Gulf basins may be roughly drawn from the western coast of Mexico to the Lesser Antilles, or over an east-and-west extent of 36° of longitude, and from the northern parts of South America to Porto Rico and the lower parts of the Mississippi Valley. Practically the whole of Central America is included in this region, whose area may be approximately put at

twice that which is represented in the Mediterranean region of Europe. Nearly the whole of this tract, and much of the region that immediately adjoins it, is characterized by violent seismic and volcanic disturbances, and probably no region of the globe, with the exception of that of the Molucca seas, has been witness to greater catastrophic events."

It is therefore evident that in studying Antillean geology one should be prepared to find extensive manifestations of past volcanic action, and such in fact is the case. Gabb, in his geological survey of Santo Domingo, noted the predominating influence of the intrusive rocks and considered them due to a series of eruptions extending from the late Cretaceous to post-Miocene times.⁵ The apparent scarcity of rhyolitic and basaltic rocks in Santo Domingo is notable; Gabb observed the absence of what he termed true volcanic rocks, consequently he could not have been cognizant of the existence of tuffs, which he appears to have considered "jaspery slates."⁶

Although volcanic activity in Tertiary times was great and extensive in the larger Antillean islands, no evidence exists of there having been any in the Quarternary period; in this respect these islands differ radically from the Lesser Antilles, where we have the yet active volcanoes of Pelée and La Soufrière of St. Vincent. The recognition of a close relationship between the Antillean geology and that of the neighboring continental areas was a brilliant generalization and a great step in advance. A consideration of their correlative economic geological relations would appear to be the next stage, but until we know much more of the countries thus affected it is impossible to go further than draw a few inferences of doubtful value, and it would seem well to avoid the question at present, confining ourselves to recording some facts that have come recently to notice.

The existence of gold in the streams of Santo Domingo, Cuba, and Porto Rico was known in the days of Columbus, and the copper deposits at El Cobre, near Santiago de Cuba, were operated by the Spaniards at a very early date, but with this exception no actual mining was done by them in America until modern times. In Santo Domingo for a number of years much gold was washed from the stream gravels, but no attempt was made to exploit any other mineral deposits, and it is doubtful if their existence was known.

Within the past ten years several efforts have been made to develop the promising copper prospects on the Nigua river in the San Christobal district of this island. For various reasons they have not been successful, although excellent ore carrying a considerable proportion of gold has been found in the veins or fracture-zones that traverse the great masses of hard tuff lying between the Jaina river on the east and the Nigua on the west. At least one such mineralized zone, running in a north-northeast direction for a distance of a mile or more, has been traced from the Nigua river. At the crest of San Francisco hill, which rises above the Nigua some four or five hundred feet, this zone begins with a width of about 30 ft. between its boundary walls, as shown in Fig. 1. Near the surface it is thoroughly decomposed into a chloritic friable mass, containing little or no copper minerals. About 150 to 200 ft. farther down the hill a section shows the zone to be split by intervening country rock. The decomposition here is slight and the mineralization greater; much quartz with some excellent chalcocite and bornite ores are found, but no chalcocite, which is disappointing, since it is evident the upper

portion of this zone or vein has been thoroughly leached and a re-deposition of the copper salts might be expected at this point. As is frequently the case in copper veins, the gold content is apt to be greater near the outcrop than in the less oxidized portions of the deposit. The outcrop on the surface of the mountain shown in the photograph (Fig. 1) is altogether barren; the maximum amount of gold appears to be in those parts of the zone or vein where the sulphides have been altered to the oxy-carbonates—malachite, azurite, etc.—and does not vary with the ratio of copper. The gold ranges from as high as \$7 per ton, while the copper content in hand-picked ore averages from 5 to 15%. Near the limestone contacts the bornite disappears entirely and the gold drops below one dollar per ton, whereas the proportion of silver shows a slight, and the iron a great, tendency to increase.

The tuff, in which these copper minerals are found, possesses some notable characteristics.⁷ When exposed

Fig. 1. On San Francisco Hill.

to weathering, as on the top of the hills, it decomposes readily into a soft clayey material that near the veins contains a large proportion of epidote and chlorite. When unaffected by atmospheric decay, as in the stream-beds where mechanical erosion has kept the surface fresh and clean, this tuff is excessively hard, dense, and breaks with a broad conchoidal fracture; it possesses varying shades of dark gray, green, and purple tints.

This coloring is decidedly peculiar; the bands of different shades range from a few inches to a foot in width and often extend entirely across an exposure. They are not uniform in width, sometimes they end abruptly, taper out, or widen, and enclose areas having the characteristic color of the surrounding rock. The lines of demarcation between the differently colored bands are straight, regular, and very sharp. These tuffs possess a fairly uniform system of fissures, frequently so regular as to resemble stratification, but others equally well marked cross them in entirely different directions; sometimes several systems of fracture occur together. The mass in the bed of the Nigua river shown in Fig. 2 exhibits this

characteristic fissuring, and also possesses the varicolored banding above mentioned, but it was impossible to indicate it in the photograph. The general trend of the tuff masses at this place is to the northeast, with an apparent dip to the south. The ore-bearing zones have a similar strike and dip; and if they can be assumed to have any regularity in strike, it is to the northwest. Cross-zones or veins with a northwest and southeast trend also occur, and it is at their intersection that the best ore is likely to be found.

Perhaps the most notable characteristic of these tuffs is the presence in them of large segregations of epidote. When exposed to the atmosphere these clusters decompose faster than the rock-mass, leaving pits or holes about the size of a walnut, as is shown in Fig. 3. When the same rock is under water in the stream, the body wears away faster than the epidote clusters, leaving them protruding from the mass as lumps or bosses.

Fig. 2. In Bed of Nigua River.

From this it is evident that the tuff is either softer than the epidote or more soluble in water. Examined under the microscope the transition of the tuff into almost pure epidote is exceedingly sharp, there being no grading or intermediate stage. This fact is perhaps suggestive of the origin of these epidote aggregations, accepting the hypothesis that the tuff was originally in a plastic or semi-plastic condition, and contained gas or air bubbles that produced globular or vesicular cavities in which the epidote collected and crystallized. It seems curious, however, that the filling of such cavities appears to be exclusively of epidote, though it might be well, in the absence of a much more extensive examination of the region, to assume this is not always the case. The fact remains, however, that except in one instance where quartz was observed filling some small globular cavities, no other mineral has yet been found in them. The microscopic structure of this tuff is shown in the microphotographs Fig. 4 and 5, the former being a typical example of the rock itself, while the latter is a section of a small quartz vein in the tuff. In Fig. 5 the dark mottled segment in the upper part of the figure is tuff, that is, the country rock. The line of demarcation between it and

⁷Gabb considered these tuffs to be altered sedimentary rocks and refers to the occurrence of similar deposits in Jamaica. *Loc. cit.* p. 190.

the quartz vein is sharp. The darker shadings in the quartz itself are mostly chlorite with some malachite, and the dense dark mass in the lower right-hand corner is limonite. Although the dividing line between the tuff and the quartz vein is well defined, the country rock is filled with green chlorite for a relatively long distance from the vein. This mineral is intimately associated with the particles constituting the rock, and is undoubtedly due to its alteration. It seems probable that the copper minerals themselves are due to secondary concentration, at least in part.

These tuffs are often cut by basic dikes of a basaltic or diabasic character, as shown in Fig. 6, which is the photograph of a rock in the bed of the Nigua river near San Francisco, in the San Christobal district. It is evident that the dike material must be softer or more soluble in water than the enclosing rock, as the dikes are some six or eight inches below the surface. The microscope shows this dike material to be composed of lath-shaped feldspars with some augite, the mass being sprinkled or peppered with fine grains of magnetite⁸.

In this neighborhood, the tuffs are sometimes associated with rhyolitic porphyry containing phenocrysts of

in the case of the iron ore deposits of the Crystal Falls district, in Michigan.¹⁰ Here the tuff deposits are grouped under the term 'pyroclastics of the Hemlock formation,' and include breccias and dust accumulations of both eolian and aqua-sedimentary origin; that is, the dust deposits may have been formed in the air, drifted into heaps by the wind, or laid down in water as a semi-stratified formation. A more common condition was probably that of mud, the condensed steam from the volcano mingling with the dust, thus forming the great mud flow so often witnessed in modern volcanic eruptions. The hardening of this material produced rocks of a basic or acid character, as determined by the proportions of silicious and alkaline bases. In the case of the Crystal Falls deposits, which are of pre-Cambrian age, both the tuffs and breccias are basic.

A tuff is usually regarded as a rock or deposit composed of the finer fragmental ejectments from explosive eruptions of volcanoes, the coarser material being denominated, when consolidated into masses, volcanic breccia or agglomerate. Some confusion appears to exist regarding the correct definition of the word 'tuff,' and it is not a satisfactory term when applied to certain classes

Fig. 4.

orthoclase and quartz, but it is not clear whether these particular rocks are associated with the ore deposits or have played any part in their genesis. As previously intimated, it is notable that ore deposits of approximately sufficient size to be workable should be found in tuffs, as they are not usually regarded as ore-bearing rocks. Taft, in his remarks upon the Bullfrog district in southern Nevada, observes:⁹

"The older tuffs are mineralized, and the more recent (upper) are not; the older are basic, while in the upper there is a flow of rhyolite. At Tonopah it is quite noticeable that the rhyolite is more recent than the 'mineralized porphyry.'"

It is evidently an error to assume, as has been done, that tuffs are necessarily a semi-solidified volcanic dust or scoriaceous material, and cannot exist as hard, dense rocks, sometimes ore-bearing, and probably playing an important part in the genesis of the orebodies contained in them and in other associated rocks of an entirely different character. While the importance of this subject does not appear to be generally recognized, its bearing in certain specific cases has been clearly understood, as

Fig. 5.

of volcanic rocks for which we appear to have as yet no better name, except the general indefinite expression 'pyroclastic.' Moreover, the word 'tuff' is often confused with 'tufa,' which is usually and correctly understood to be a material deposited by the solfataric action of hot water or steam. A mud composed of volcanic ejectamenta or dust may resemble similar material deposited by geysers and mud springs, but it appears highly probable that they have different origins, and should not be confused. For practical purposes, therefore, the word 'tuff,' in want of a better term, may be applied to more or less consolidated deposits composed of finely powdered volcanic fragments or dust. The consolidation may be the result of pressure, the cementing action of accessory material such as silica, and iron oxide, or a combination of these and other agencies. It is also conceivable the ejected fine particles of mineral matter may be in a sufficiently highly heated condition to be plastic or soft and to stick together, thus forming a spongy mass that subsequent pressure could weld into a solid rock.

⁸Trans. Am. Inst. M. E., Bulletin 6, Nov. 1905, p. 1,287.

⁹The writer is indebted to Mr. F. J. Keeley, of Philadelphia, for the preparation and identification of the microscope sections used in this paper.

¹⁰The Crystal Falls Iron-Bearing District of Michigan, by J. M. Clements and H. L. Smyth. U. S. Geol. Surv., 19th Ann. Rept. (Pt. III), p. 50.

The fact that ore deposits of commercial value may be found in indurated tuffs has not yet been generally recognized. H. H. Taft, in writing of certain gold deposits in southern Nevada, observes¹¹: "It is remarkable that so many mines have been found of late years in the volcanic tuffs, now generally known as andesite. A very large proportion of them carry gold. One cannot but wonder if there are not more. This is not a formation which prospectors have liked until lately; and as yet it has been but imperfectly studied. The fact that the mineral-bearing tuffs are basic, and are overlain by the acid rhyolite, is perhaps significant."

J. E. Spurr, in his monograph on the Tonopah district, Nevada,¹² calls attention to certain ore-bearing tuffs in Japan. Reference to the Japanese authorities develops the fact that there are a large number of localities, especially in northern Japan, where gold, silver, and copper in apparently workable quantities exist in tuffs, usually associated with Paleozoic rocks.¹³ These Japanese tuffs are associated with andesitic and rhyolitic flows, chiefly of the Tertiary period; the ore deposits, or aggregations of metallic minerals, appear to be chiefly or wholly in tuffs of a basic character and consist mostly of chalcopyrite, bornite, argentite, with occasional galena and zinc-blende.

At Potrillo, in the State of Durango, Mexico, cassiterite occurs in rhyolite-tuff along fault-planes in aggregations or nuggets, and occasionally in bands of crystalline minerals replacing the country rock between two sheet-planes. Other tin orebodies of less importance are found as ill-defined replacements of the country rock and there is some evidence that the source of the tin of this district existed as an original constituent of the country rock.¹⁴

Going west into California, we find that the greenstones of the Mother Lode gold deposits, although recognized as of sedimentary origin, are in fact derived from tuffs and eruptive detritus.¹⁵

These references might be multiplied were it necessary to further elucidate the subject; the close relationship of such consolidated volcanic ejectamenta to ore deposits and their effect upon the genesis of orebodies, whether in tuff itself or in associated rocks of different construction, is evidently a subject worthy of consideration, and one that appears to have been little understood in the past, or perhaps, what is more probable, such tuffs were classed as other kinds of rock, their actual structure being misunderstood. This is probably due to the fact that the finer tuffs are often so silicified as to be undistinguishable from massive rocks, except under the microscope.¹⁶ Rickard, in speaking of veins in andesite at Cripple Creek, does not distinguish between tuff and fine-grained andesite, which he says in the vicinity of the lodes is impregnated with the quartz to such a degree as to obscure its fragmentary character, and make it resemble phonolite.¹⁷ Purington similarly refers to the San Juan breccias of the Inogen basin, in Colorado, as andesite. He describes it as containing fragments of andesite, generally angular, in a tuffaceous matrix whose origin is igneous, and water-laid. It is extensive in the San Juan mountains (Colorado) and at its horizon most of the present productive mines of the district are situated.¹⁸ It is evident, therefore, that tuffs vary according to the character of the magmas from which they were derived in the volcano. Thus, in a region of basalt we have basaltic breccias

and tuffs; likewise in andesite, such rocks would have an andesitic nature, and so on.

Coming now to the consideration of the origin of the ore deposits that are the subject of this paper, we are confronted with some facts difficult to understand.

The ore deposits on the Nigua river may, for convenience, be divided into two groups. Segregations of copper minerals in tuffs on Bocara hill near a limestone contact, and veins or fissure-zones on San Francisco hill. The deposits of this last group can be traced in a northeasterly direction toward the Jaina river, a distance of three or four miles. On Bocara hill the ores appear to be magmatic segregations, and not veins, fracture-zones, or deposits in pre-existing cavities. The copper minerals seem to be localized in spots in the country rock. On the surface of the hill, where there has been much weathering and little erosion the mineralized segregations, being harder than the tuff, stand out in relief, in one instance forming a kind of blow-out. Lower down the hill (Bocara) where the rock has not been so much weathered, or at least where the products of decomposition have been eroded, the mineralized spots or streaks have the appearance of veins, but they are discontinuous and erratic in occurrence. The rock surrounding them is intensely hard and difficult to work. From a boulder dug out from the decomposed tuff on the top of the hill, an analysis was obtained, showing 8.17%, chalcopyrite; 26.34, malachite; 24.53, limonite; 24.78, quartz; 16.18, chlorite, and other silicates undetermined. This gives us an equivalent of about 17.95% copper and 17.20% iron.

If it is assumed that the copper minerals were aggregated when the rock was in a fluid or semi-fluid condition, we are confronted with the fact that in the nature of things a tuff, that is, a dust or fragmentary deposit, could not have been in such a condition after its deposition without the destruction of the fragmentary structure by fusion, which is not the case in this instance. The nearest state to this condition we might reasonably assume would be that of plasticity or semi-fluidity to a point short of an actual fusion of the individual particles composing the mass. The question then arises, could a segregation of metallic sulphides take place under such a condition? It is difficult to conceive how it could, unless there might be some sort of molecular flow or diffusion in accordance with Soret's principle of molecular concentration caused by differences of temperature. This hypothesis assumes that in a homogeneous solution unequally heated in different parts, concentration will be greatest in the region of lowest temperature.¹⁹ Of course, a rock of this kind is not a homogeneous body, and as it is not a solution we cannot assume the existence of osmotic pressure, as suggested by Park in the case of molten magmas.²⁰ It would therefore appear that the most plausible hypothesis to account for these segregations of metallic mineral would be the action of water or aqueous vapor. In the absence of cracks, seams, or ducts in the tuff, by which such an aqueous medium could travel, there seems to be left only an assumption of capillary circulation.

A disposition appears to exist of late to discredit the lateral secretion theories of Sandberger and assume in economic geology that the valuable metallic minerals necessarily come from the indefinite 'below,' just as in old-fashioned theology all good was ascribed to an equally

intangible 'above,' with as much sense in one case as in the other. Possibly some persons familiar with the volcanic rocks of the Great Basin in Nevada, Arizona, California, and Mexico, have observed in places the remarkable—almost universal—existence in them of traces of gold. De Kalb, in speaking of the pegmatites at the Exposed Treasure butte near the Tehachapi mountains in the Mojave desert, California, observes: "It is worthy of note that these pegmatite dikes rarely show, by samples taken at random, a value in gold lower than 20c. per ton, and many of them, particularly in the Rosamund mountains, often assay as high as \$1 per ton. The granite itself is never barren, but seldom carries more than 0.001 oz. gold per ton. The absolutely universal dissemination of gold throughout all rocks in the entire district, requiring no refined methods of analysis to determine its presence, is a noteworthy circumstance."²¹

In Mohave county, Arizona, I have myself found traces of gold in pegmatite, schist, gneiss, basalt, diorite, rhyolite, trachyte, and tufa, all within an area of ten square

Fig. 3. Pitted Tuff.

miles. There are also to be found at this place (Weaver district) rich superficial deposits of gold-quartz ores, mostly oxidized but with occasional specks and spots of sulphides, having no apparent connection with any deep-seated vein or duct; the veins are nearly horizontal, or but with a slight dip to the east. In the absence of proof to the contrary, one is forced to the conclusion that these deposits had their origin by lateral secretion and leaching of the surrounding rock.

Referring again to Bocara hill, on the Nigua river in Santo Domingo, repeated efforts to find bodies of ore large and rich enough to work have failed, and the only promising deposits so far prospected are the fissure-zones or veins on San Francisco hill, fully a mile distant and about half a mile from the nearest limestone outcrop. The ore in these fracture-zones (as I prefer to consider them) is rich and carries gold, and if found in quantity would make a valuable mine. The great fissure or fracture-zone at this place is more or less regular, but the mineralization is uncertain and discontinuous, the ore-body or pay-streak suddenly stopping and pinching out

in a most unexpected manner. The parting, or separation of the vein from the country rock, is also indistinct and in many places it could be said that there are no vein-walls, the ore shading into the rock. From the indications here it would seem that the original vein-filling or mineralization had a deep-seated origin, subsequently enriched by a downward leaching and re-disposition of the copper, since the ratio of this metal increases with depth, while the proportion of gold is greatest in the partially leached portions of the vein nearer the outcrop. This observation as to the greater proportion of gold near the outcrop, in the case of copper deposits, has been repeatedly noted, especially in fissure veins. When the oxidized, or upper parts of orebodies have been removed by erosion, as in Alaska, the sulphide zone is practically at the surface, and there has been no time for leaching and re-precipitation at lower levels, owing to the steady

Fig. 6. Dike Cutting Through Tuff.

removal or planing down of the outcrop by ice and other destructive agencies.

The genesis of the fissure veins, or zone deposits, on San Francisco hill, may be safely assumed to have combined in their origin lateral secretion, re-precipitation of solutions from the outcrop, with some proportion of metal from a deep-seated source.

Although the lines of demarcation between the vein and country rock is not always distinct, and there are frequent evidences of a metasomatic replacement of the rock by the copper minerals, while the veins are at times distinctly defined, as in the microscopic section shown in Fig. 5.

I can see no reason why an ore deposit in tuff rock should not have an origin similar to one in a solidified magma. For example, the constituents of an andesitic tuff must be practically the same as an andesitic magma, and if the metallic minerals were derived from the body of the enclosing rock, the results must be similar in either case. If the metal-bearing solutions came from greater depths than the enclosing rock, or even if they were derived from lateral secretions, there is no reason to suppose the fissures in a magma would offer a more

²¹ *Trans. A. I. M. E., Bulletin 13, p. 17. Jan., 1907.*

hospitable or favorable site for deposition than the crevices in the hard, dense, consolidated tuff. I am of the opinion that ore deposits cannot usually be ascribed to any one set of phenomena, but to combinations of forces acting together and separately at different intervals. It is a mistake to assume that any one particular agency has been the sole and only medium of deposition; in fact, I doubt if this is ever the case. Ore deposits as we find them are the finished products of Nature's great laboratory, with its multitude of forces and complex systems of construction and destruction, still going on upon the surface and in the interior of the earth. Gradually we learn something about them and by turning this modicum of knowledge to practical account we have evolved the science of economic geology, which is geology, chemistry, and physics applied to practical mining. But such tools can be safely used only by a trained hand and mind; how dangerous they are to the unskilled is to be seen today in every mining camp.

DIAMOND-CARBON IN METEORITES.—The results of careful researches on the Canyon Diablo meteorite showed (1) that it is only in certain specimens of this meteorite that carbon appears at all; (2) that in some pieces it is present in several forms, as amorphous carbon in two or three distinct varieties, as graphite, and as diamond in two varieties, black and transparent; (3) that these latter are found inclosed in or surrounded by a zone of amorphous carbon and in small fissures which stand in close relation to nodules of troilite and other compounds containing phosphorous and silicon in addition to the sulphur. Microscopic examination shows that even the portions of the iron that appear homogeneous frequently contain small nodules of this character. The metalloids—silicon, phosphorus, and sulphur—all tend to displace the carbon from molten iron, and an increase in the proportion of nickel, which is found to vary considerably in different parts of the meteorite, lessens the solubility of carbon in the alloy as compared with pure iron. These two conditions, therefore, should co-operate to favor the separation of carbon in such a meteorite. A series of new experiments was made to test the effect of conditions thus modified, with the general result that the addition of small quantities of monosulphide of iron, or of silicon, to the crucible of melted iron with carbon, on its removal from the electric furnace and just before its immersion in cold water, appeared to facilitate the production of minute diamonds. The addition of a small percentage of nickel, on the other hand, produced no apparent change from the results with pure iron. The introduction of phosphate of iron not only failed to increase the quantity of diamonds but apparently lessened it. Therefore it was concluded that the diamond-carbon in the Canyon Diablo meteorite has probably been set free from an iron carbide by the action of sulphur, and to some extent of silicon, the latter having also partly united with the carbon to form the silicon carbide in association, the natural form of the artificial product carborundum. In a number of instances the little crystals broke spontaneously days or even weeks after their formation, thus presenting a striking parallel to the occasional behavior of diamonds from the blue ground of South Africa.

MINING for beryl has been carried on more or less extensively in North Carolina, but without much result. It has been found, however, in the Spruce Pine region that by deeper mining blue beryls are frequently obtained at a greater depth than any previously taken out, and in some quantity. Many gems have been obtained weighing from three-fourths of a carat to two carats each, but few are over four carats in weight.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

A piece of Andesite was sent from Oaxaca, Mex., by H. A.

A fragment of Gabbro was sent from Silver Star, Mont., by C. L. D.

The rock from W. W. G., of Comer, Ore., was reported as an altered Andesite some weeks ago.

The two specimens from H. A. Mc., of Rebel Creek, Nev., are: No. 1, Pyrite and Molybdenite in quartz; No. 2, Quartzite.

W. L. G., of Fairview, Nev., sends: No. 1, Andesite; No. 2, Andesite; No. 3, Basalt; No. 4, Andesite; No. 5, Rhyolite; No. 6, Dacite.

The specimens sent from San Diego, Cal., by B. C. are: No. 1, Quartzite; No. 2, Pegmatite; No. 3, fine-grained Granite; No. 4, Pyrite.

W. L. R., of Victoria, B. C., sent a specimen of Tremolite, carrying andradite garnets and a vein of magnetite which is stained with red hematite.

The specimens sent from Mocorito, Mex., by R. M. H., are: No. 1, Dacite; No. 2, Andesite; No. 3, Calcite; No. 4, Andesite; No. 5, Andesite; No. 6, Andesite.

The rock specimens sent from Tonopah by R. C. N. are: A, Dacite Porphyry; B, Dacite Porphyry; C, Andesite; H, Dacite Porphyry; K, Dacite Porphyry.

G. B. sent from Buckeye, Ariz.: No. 1, Sepiolite; No. 2, Epidote; No. 3, Granite; No. 4, Siderite; No. 5, Quartz stained with iron; No. 6, Granite; No. 7, pegmatite Granite; No. 8, Andesite.

The specimens from L. B., of Kerby, Ore., are: No. 1, Serpentine with a bluish stain due to iron; No. 2, Mica Schist; No. 3, Actinolite; No. 4, Glaucofane Schist; No. 5, Diorite. The serpentine shows no indications of copper.

The specimens sent from Blair, Nev., by C. S., are: No. 1, Pyrite; No. 2, Quartz; No. 3, Quartz and Limonite stained with malachite; No. 4, Galenite in quartz; No. 5, Pyrite in quartz; No. 6, Quartz and Arsenopyrite; No. 7, Gabbro; No. 8, Calcite; No. 9, Obsidian.

PYROPE IN NEW YORK.—An interesting discovery of pyrope garnet was made in constructing the rapid transit tunnel from the south end of Manhattan island to Brooklyn. This tunnel runs from the Battery at the foot of Whitehall street to the foot of Joralemon street, Brooklyn. About 1,000 ft. south from the New York starting point beautiful grains or nodules of pyrope were obtained, capable of being cut into gems of three-fourths of a carat to one carat in weight. These were in connection with serpentine—some of the green precious variety—together with kerolite. Pyrope is a mineral belonging to igneous rocks, especially peridotites, from the alteration of which serpentine is frequently formed. The serpentines of New York and vicinity are now quite clearly shown to have originated in this way.

Arbitration: Compulsory and Voluntary.

*In all the three States of Australia where Compulsory Arbitration Acts are on trial the principle has broken down so badly in actual working that its advocates can now claim for it virtually only one merit. They can say that, whatever may be its defects, a Compulsory Arbitration Act does place one barrier, albeit a frail one, in the way of settling industrial disputes by the summary methods of strike or lock-out. There is undoubtedly some force in that contention, although, so far as strikes are concerned, the barrier has proved so frail as to be practically worthless; and although compulsory arbitration, when it is successful in this respect, leads to other evils that outweigh the value of its success. As with nations, so with classes, the ultimate arbiter of disputes is, and must always be, force—war in the one case; strike or lock-out, or boycott, or something equally drastic, in the other. But as with national, so with industrial disputes, it is possible to place barriers in the way of a resort to force; and the stronger and more efficacious these barriers can be made, the better it will be in the long run, not only for the disputants themselves, but also for others not directly involved as parties in their dispute. Compulsory arbitration having proved ineffective as a barrier in industrial disputes, the question naturally arises whether something better and stronger cannot be devised and substituted for it.

Now historical teaching, practical experience, and common sense all show that such a barrier, to be really effective, must be constructed of the two materials: compromise and arbitration. Keeping that fact in view, and by way of clearing the ground for an answer to the above question, we may briefly point out the reasons, which we have already fully dealt with in previous articles, why compulsory arbitration has failed; and then we shall be able to see more clearly how what is faulty in it may be remedied.

First, then, the element of compulsion in the existing Acts is fatal to their success. There is an old adage that you can bring a horse to the water, but you cannot make him drink. Just so, you may force men into the Arbitration Court, but you cannot make them abide by its decision. The award once given, the Court has no power to enforce it. It may be argued from this that the Acts are not compulsory enough; that the Court should be able to punish men for the non-acceptance of any award, just as a magistrate can send a thief to prison for stealing a watch. But that can never be. No power could make an employer carry on business under conditions that would mean his financial ruin, nor can any power make a man work for a specific wage against his will.

So long as an award is accepted by both sides and work continues under it, the Court has power to punish either side for any breach of that award. But it has been shown over and over again in practice that the Act is so one-sided in its application that, while the penalties prescribed for a breach of the award are readily recoverable from the employer, they either cannot be enforced against the employees, or can be recovered from them only with considerable cost and difficulty.

Another aspect of the one-sided operation of the Act is seen in the fact, to which we have already alluded, that, when an award is given, if it meets wholly or substantially the demands of the workers, they are quite willing to accept it; if, on the other hand, it fails to satisfy their requirements, they at once cease work, and revert to the old method of a strike to get what they want. We do not, of course, say that they do this in every case, but

they have done it in so many instances that such action has become almost a recognized rule. The ordinary working man, in fact, whether as an individual or as a collective trades union, looks upon the Arbitration Court, not so much as a responsible court of law whose decrees are to be respected, but rather as an institution established by Parliament at the bidding of the Labor members for the express purpose of giving to the workers higher wages or shorter hours, whenever they choose to ask for them. As long as its decisions are adverse to the employer, the Court is doing its proper work and its decisions are to be loyally accepted; but when they are adverse to the employees, the Court stands self-condemned of failure, its award may be challenged as unjust and arbitrary and tyrannous, and may be rightfully and with impunity disregarded in favor of a strike.

It may be urged that it is open to the employer to act in like manner. If he is dissatisfied with an award, there is nothing to prevent him from closing down his business and discontinuing his industry. This is perfectly true; but the cases are by no means parallel. There is all the difference in the world between the throwing down of their tools by a number of workmen and the stoppage of a whole industry by an employer. Such stoppage means ruin to the employer himself, probably also ruin to a thousand workmen for a hundred affected by the award, and great inconvenience to the public. If in consequence of an award adverse to them, some of his men go out on strike, he can still carry on his business, though hampered and embarrassed, and trust that he will gradually replace the strikers by men willing to work under the terms of the award. But, on the other hand, sooner than close down his industry altogether and sacrifice the capital he has invested in it, he will submit to almost any exactions on the part of the Arbitration Court.

In such circumstances it is only natural that the employer should seek to make good in some way or other the loss he has sustained by an adverse award. The most obvious, and, consequently, the usually adopted course, is for an employer to put up the prices of what he produces, and so to compensate himself for the enforced payment of higher wages. The result, as seen in New Zealand, is inevitable; the increased wages will in the long run not benefit the workmen at all. In New Zealand, as we have noted, the Compulsory Arbitration Act has been comparatively successful, by which we mean that its working has led to less open friction in New Zealand than elsewhere. And what has been the result? An official report issued about a year back by the Secretary of the Labor Department in that colony draws a very gloomy picture of the state of affairs. He emphasizes the fact that Arbitration Court awards have increased considerably the wages paid to workmen; but at the same time he points out that the cost of all necessities of life has increased in a still greater ratio. It therefore follows that the enhanced wages now paid to workmen have not as large a purchasing power as the lower wages that previously ruled, and, consequently, to quote Mr. Seddon, "the workmen are no better off."

An examination into the working of the Compulsory Arbitration Act in New Zealand or elsewhere makes only too clear the fundamental fallacy that underlies and undermines it. The Act is based upon the fallacious assumption that the natural law of supply and demand can be superseded at will by the artificial law of the statute book; that the State can, by passing an Act of Parliament, at any moment fix for a definite time the relative value of two commodities, work and wages. Precisely the same fallacy has always wrecked every attempt to put into practice the theory of bimetalism, for no

* From the *Journal* of the Chamber of Mines of Western Australia, April, 1907.

government yet has found itself able to establish arbitrarily a fixed ratio between the values of the two commodities, gold and silver. Similarly, no court can establish, with any degree of satisfaction, a fixed ratio between work and wages. A legal authority pointed out in this journal some time ago that in cases involving the relations of employer and employee the tendency of judges nowadays was to favor the latter at the expense of the former. So it has been with the Arbitration Court. It is a simple fact that in almost every case brought before these Courts wages have been fixed at too high a rate. The result has been inevitable. The employer, to recoup himself, has been forced to raise the price of the product of the work for which he has been compelled to pay a higher wage. He has thus restored the equilibrium of supply and demand so far as he is personally concerned, but in so doing he has disturbed that equilibrium elsewhere. The natural result has been that the prices of other commodities have been forced up, wages have risen in other branches of industry, the cost of living has been increased all around, and yet nobody benefits. Not even the workmen benefit by the increased wages they get, for the purchasing power of their wages remains the same as it was before. The State—and with the State every member of it—suffers by this condition of affairs, for, with the cost of production enormously increased, the State is seriously handicapped in its competition with other nations for the sale of its products in the markets of the world.

Before leaving this phase of the subject we may note that there is one industry alone in which the employer is debarred from raising the price of his product in order to compensate himself for the payment of higher wages. That industry is gold mining. Gold is the universal standard by which all commodities are valued, and therefore its price is theoretically unalterable. The theory is not quite true. The truth is that the value of gold—its purchasing power—has steadily depreciated and is depreciating, but the alteration in its value is so steady and so slight from year to year that for all practical purposes it may be, and is, regarded as unaltered. Hence, when the wages of miners are raised the owners of gold mines cannot resort to the obvious remedy open to other employers, and their power of recouping themselves for exactions is thus greatly curtailed. All they can do is to lessen the cost of production by all means possible, to pick the very best men they can get, and in other ways to balance increased wages by decreased working expenses or larger output. But this process cannot go on forever, and the mine-owner must reach the limit sooner than other employers, when he must abandon work and throw his men out of employment. This process has already begun its harmful work even in this young State, where many mines have been compelled to close down because they cannot afford to pay the high wages ordered by the Court.

The failure of compulsory arbitration here and elsewhere may not be unproductive of good if its lessons be read aright. The principle of arbitration for the settlement of disputes, whether they be international or industrial or social, is an excellent one; in fact, it is the only one short of an appeal to force. But to be effective it must be voluntary. That truth was clearly recognized by the delegates to the first Peace Conference held at the Hague five years ago; it is recognized in the English Conciliation Act of 1896; in the constitution of the Conciliation Court established in France; and in the methods of the State Board of Conciliation in South Australia.

The difference between voluntary and compulsory arbitration is just this, that the former requires both parties to a dispute to ask for arbitration and set the necessary

machinery in motion, while the latter necessitates action on the part of only one party to the dispute to bring a case before the Court. Thus, in the case of compulsory arbitration, the principle of compromise, which is essential to any effective agreement, is practically eliminated altogether. The attitude of the two parties before a Compulsory Arbitration Court is aggression on the one side and resentment on the other. Whatever the award may be, it is certain not to satisfy both parties, and the one which considers itself aggrieved will either repudiate the award altogether or resort to other devices to counteract the effects of it.

Of voluntary arbitration, on the other hand, the very essence is compromise and fair dealing. If a dispute arise between two parties, and if they fail to come to a satisfactory agreement after talking matters over, they decide to submit it to arbitration. Both parties are pledged beforehand to accept the award, whatever it may be; and both are ready to pledge themselves to that effect because they know that it will be just and equitable and will be given with a full knowledge of all the circumstances of the case. Thus in England, about a couple of years ago, a disastrous strike in the Lancashire industry was averted by voluntary arbitration, both sides readily submitting to the award given. Had a Compulsory Arbitration Act been in existence the employers in both cases would probably have been forced into Court, and after a long and expensive inquiry an award would have been given with which one side or the other would have been bitterly dissatisfied.

The whole tendency of voluntary arbitration is toward industrial peace. Under it there is no opportunity, such as a Compulsory Arbitration Act affords, of making a mountain of agitation out of a molehill of pretext, and bringing to arbitration some frivolous dispute that could easily be settled by five minutes' friendly conversation between employer and employee. The whole tendency of compulsory arbitration, especially when the compulsion is practically all on one side, is to generate industrial irritation, friction, and strife. Voluntary arbitration teaches employers and employees to regard themselves as friends and allies, bound together by ties of common interests, and prepared to sink or adjust minor differences in order that they may the better work together for their mutual benefit. Compulsory arbitration forces employers and employees into mutual bitterness and hostility; it compels them to look upon each other as enemies, not as allies; it makes the main object of each to exact from the other the uttermost farthing that the law allows, while the interests of the industry upon which they both depend are neglected and impaired, to the ultimate and inevitable detriment of both.

Without going into the details of its practical application, we are convinced that in the principle of voluntary arbitration, in providing the machinery for compromise and arbitration to which both parties may voluntarily resort, will be found the only effective means of satisfactorily settling industrial disputes and of preventing, so far as they can possibly be prevented, such mischievous methods as strikes and lock-outs. To quote one prominent labor leader in America: "Arbitration, to be practical, to be beneficial, must be entirely voluntary. Compulsion and arbitration are in themselves contradictory terms; there can be no real arbitration that is compulsory." And another writes: "The growing movement is toward organization among employers and workmen, which affords the perfect machinery for facilitating settlements in disputes. In this voluntary arbitration in which representatives of capital and labor are their own arbitrators, I believe lies the perfect harmony and the completion of economy in the industrial world."

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

ORE STAMP-MILL.—No. 859,044; James E. Brooks, Crawfordsville, Ore., assignor of one-half to James C. Munckers, Crawfordsville, Oregon.

A stamp-mill comprising a base, a body mounted thereon and having a die recess surrounded by an annular rim, a screen surrounding the rim, a lip extending from the body, an annular trough surrounding the screen and opening on to the lip, said trough having upwardly extending oppositely disposed walls, a cover bearing upon said walls and having an annular flange projecting into the screen, said cover having a central opening, a stamp guided within said opening and disposed above the die, a dome extending upward from the cover and over the stamp and opening, a feed spout extending along one side of the dome and through the cover, said spout being disposed to feed material into the screen and toward the stamp, and a gravity actuated door suspended across the discharge end of the spout.

STAMP-MILL.—No. 860,307; Pierre N. Leveque, Lead, South Dakota.

A device of the character described comprising a bar having its lower end engaged with a fixed pivot in a stamp-mill to permit its upper end to be swung into and out of the path of a tappet, said bar having at its upper end a horizontally extending portion to engage the stem of a stamp, a vertically extending stop portion, and a bearing, a bell crank fulcrum in said bearing, and having an arm to swing between the horizontal and vertical portions of the bar, and to engage the bottom of a tappet to raise and lower the same.

ORE-FEEDER.—No. 853,346; Henry Eggers, Denver, Colorado.

In an ore feeder, the combination of the frame, provided with floor rollers and an inclined vertical shaft at one end, with an ore feeding disk secured to said shaft, an ore hopper in said frame, having its discharge aperture resting close onto said disk and arranged to discharge thereon, ore guards arranged to guard the ore from said discharge aperture to the discharge edge of said ore feeding disk, a frictional disk secured to said shaft, a pair of roller supporting arms pivotally mounted on said shaft on opposite sides of said disk, a wedge between each roller and said frictional disk, and arranged to have a slight reciprocal movement of said rollers, resilient means for normally holding said rollers in engagement with said wedges, a reciprocating rod spring controlled in one direction of its movement, connected to said roller supporting arms, and means for moving said rod in the opposite direction of its reciprocal movement.

ELECTRIC SMELTING.—No. 861,280; Paul L. T. Héroult, La Paz, France, assignor to Societe Electro-Metallurgique Francaise, Froges, France.

In the smelting of iron ore in an electric furnace having an electrode from which the current passes to the base of the furnace, the process which consists in feeding a charge of ore and carbon in such proportion that the carbon forms a magma below the electrode, and the ore is fused above the column and is reduced in passing therethrough, and the molten iron collects at the bottom, and adding lime to the charge in quantities sufficient to form a scale of desired thickness at the sides of such column, thereby diminishing the cross-section of the column.

ORE-FEEDER.—No. 863,229; Grant B. Shipley, Milwaukee, Wis., assignor to Allis-Chalmers Company, Milwaukee, Wis., a Corporation of New Jersey.

The combination with a chute, of an inclined rotatable table therebelow, said table being provided adjacent its periphery with a drip bead, and means for supporting said table

A Magnetic Separator.

Owing to the greater cheapness of electricity, the employment of magnetic separation in ore dressing has been widened. Among the machines in successful use is the Dings Magnetic Separator, illustrated in the accompanying drawing. It is described as a machine of medium intensity, and has been used successfully in the treatment of lead ore by the Frisco Mining Co. at Gem, Idaho, where

five of these machines are now at work. Similar machines are in use by Henry E. Wood & Co., of Denver, A. R. Wilfley at Patagonia, Ariz., the Kootenay Ore Co. at Kaslo, B. C., the Colorado Zinc Co., Denver, the General Engineering Co., Salt Lake, and Claudet & Wynn, Rossland, B. C. In the illustration a double magnet is shown, but machines with a single magnet are also made. It is stated that it is possible to make five separations in one operation. The ore is fed from the hopper upon a vibrating conveyor over which it passes in a thin layer through four zones of separation. These are covered by rims of rotating wheels carrying secondary magnets, which attract and remove the magnetic material, discharging it over the sides of the conveyor. The secondary magnets are saturated by pole pieces of powerful primary magnets, while over the conveyor, but are automatically demagnetized as they pass out of the magnetic circuit to the neutral position where the rims of the wheels overhang the conveyor. The non-magnetic heads pass for final delivery at the lower end of the conveyor. Every part of the machine is accessible for inspection. The machine is made by the Dings Electro-Magnetic Separator Co. at Milwaukee, Wis.

Books Received.

'The Copper Mines of the World' by Walter Harvey Weed. Hill Publishing Co. 370 pages. Illustrated. Price \$4. This is a book the publication of which has been awaited with keen interest by the many interested in the exploitation of copper deposits. Mr. Weed has won so distinct a place as an authority on the geology of copper lodes that it is not necessary to emphasize his fitness for the task of preparing a book. The headings of the chapters suggest the wealth of information distributed among the pages of this volume: Distribution of Copper Deposits, Production of Copper, Mineralogy, Geologic Occurrence, Outcrops, Genesis of Copper Deposits, Classification. The second part of the book, from Chapter VIII to XXII, inclusive, is devoted to descriptions of the principal copper mines of the

world. Among many excellent features are the little outline maps of the chief copper regions and the accurate geologic sections. We congratulate the author and publisher on bringing out a book so useful and timely. For sale by the MINING AND SCIENTIFIC PRESS.

'Shaft-Sinking Under Difficult Conditions,' by J. Riemer. Translated from the German by C. R. Corning and Robert Peele. 176 pages, 19 folding plates, and 18 figures. Price, \$3. Published by John Wiley & Sons. This is a scholarly bit of work, and will appeal to mining engineers, especially to those that have had charge of, or desire to be prepared for, work in shifting strata and water-soaked ground. In the iron and copper regions of Michigan, in the coalfields of Pennsylvania, and in the sulphur and salt deposits of Louisiana, there is opportunity for using the experience recorded in this book. But to any mining engineer, the information given and the work described will be of great value. For sale by the MINING AND SCIENTIFIC PRESS.

Compressed Air Hose Connections.

Among recent improvements for handling air or steam in drilling are the new Reardon patent couplings for compressed-air and steam hose, manufactured by the Compressed Air Machinery Co. of San Francisco. The couplings, illustrated herewith, have

been designed to take the natural fall of the hose at its point of connection to the drill or machinery in the event of the hose being suspended in a shaft or coming up to the machine from the floor of the drift.

In ordinary hose, oil soon collects inside the tube at a point immediately adjoining the coupling and weakens the tube by destroying the fabric. The weight of the hose then causes a kink at this point, thus reducing the efficiency of

service. To prevent just such trouble these couplings were designed.

Catalogues Received.

THE DENVER FIRE CLAY CO. is distributing its latest illustrated catalogue of assayers' and chemists' supplies. This is a comprehensive catalogue and price list of 350 pages, and includes quotations on a great variety of chemical, physical, and general laboratory supplies.

THE ALLIS-CHALMERS CO. has issued Revised Bulletin No. 1,412, on the subject of crushing rolls. This contains complete tables and lists of parts, and should be useful in ordering repairs.

THE use of a 'slogan' in trade advertising is unique, although often used by organizations, and by some newspapers for a headline. Its usefulness is peculiarly suitable when properly placed as a headline, or in the body of advertisements in trade literature.

MINING AND SCIENTIFIC PRESS

Whole No. 2460. VOLUME XCV.
Number 11.

"Science has no enemy save the ignorant."

THREE DOLLARS PER ANNUM.
Single Copies, Ten Cents.

MINING AND SCIENTIFIC PRESS

ESTABLISHED MAY 24, 1860.

PUBLISHED AT 667 HOWARD ST., SAN FRANCISCO.

Telephone Temporary 4777.

Cable Address: Pertusola.

EDITED AND CONTROLLED BY T. A. RICKARD.

SPECIAL CONTRIBUTORS:

PHILIP ARGALL.	J. H. CURLE.
LEONARD S. AUSTIN.	J. R. FINLAY.
FRANCIS L. BOSQUET.	H. C. HOOVER.
R. GILMAN BROWN.	JAMES F. KEMP.
DONALD F. CAMPBELL.	CHARLES S. PALMER.
J. PARKE CHANNING.	C. W. PURINGTON.

SAN FRANCISCO, SEPTEMBER 14, 1907.

ANNUAL SUBSCRIPTION:

United States and Mexico.....	83
Canada.....	84
All Other Countries in Postal Union.....	One Guinea or 85

EDGAR RICKARD - - - - - Business Manager.

BRANCH OFFICES:

NEW YORK—42 Broadway.	DENVER—420 McPhee Bldg.
CHICAGO—934 Monadnock Block. Telephone: Harrison 636.	
LONDON—Leathwall & Simmons, 5 Birch Lane.	

PUBLISHED BY THE DEWEY PUBLISHING COMPANY.

Entered at the San Francisco Postoffice as Second-Class Matter.

Editorial.

MINING OPERATIONS, which were interrupted by a strike, have been resumed at Angels Camp. The union miners voted to return to work, and it is significant that "only Austrians and other foreigners voted to continue the strike." The worst forms of labor tyranny are un-American and we owe them to laborers lately released from the serfdom of the less progressive portions of Europe.

THE EXPERIMENT in the electrical smelting of iron ore in Shasta county, California, is reported to be a success. A tramway from the mine to the smelter is being built, and a plant for the manufacture of electrodes is under construction. Until the branch railroad and the tramway to the mine are completed, the smelter will be used for making ferro-silicon, which brings a higher price than pig iron. This enterprise means much to the industrial development of the Pacific Coast, and we hope to chronicle further progress soon.

OUR CONTEMPORARY in New York, in referring to the copper statistics for 1906 as published by the Geological Survey, says, in an off-hand way, that "the Survey's figure is too low and doubtless will be corrected in its final statement." This might pass in the days when R. P. Rothwell and David T. Day were bitterly opposed, both personally and in statistical exercises, but it will not do at this date, when the work of compiling the figures of metal production is entrusted to a group of capable men, intimately acquainted with the conditions under which the metals are extracted in the various mining districts. As between Mr. L. C. Graton, of the Survey, and the necessarily anonymous compiler on the staff of *The Engineering and Mining Journal*, there is every reason to prefer the former, simply because the Government has better facilities for obtaining data than any trade paper, and the obtaining of them is now in the hands of men thoroughly competent, as was not always the case heretofore.

ON ANOTHER PAGE we publish a useful article, by Mr. John M. Nicol, on the method of saving gold in the course of hydraulic mining in Oregon. Some references are made to Dr. David T. Day's experiments and a fair criticism is offered. At least it is constructive and not merely destructive. We regret that the State Mining Bureau should have published a pamphlet on the same subject recently, consisting of a reprint of matter at least ten years old and so incomplete as to have no practical value, on the top of some uncomplimentary references to the work done by Dr. Day and Mr. Robert H. Richards. Having regard to the fact that the deposits called 'black sands' are found mainly on the Pacific

Coast, it would seem proper for the Mining Bureau to undertake an adequate treatment of the subject.

Natural Resources and Railroads.

ON ANOTHER page we publish a letter from British Columbia referring to the shortage of coke at the smelters of the Boundary district and the steps taken by local authorities to discipline the coal company that is at fault. The Crow's Nest Pass Coal Company is held accountable for a condition of affairs highly detrimental to the mining industry of British Columbia. Whether its charter has been infringed and whether the Government can control the marketing of its output, remains to be seen. It is an interesting situation and is due to the monopoly of a natural resource, with many features comparable to the anthracite monopoly in Pennsylvania.
